Medical Action and Uses.—The action of cyanide of potassium is identical with that of hydrocyanic acid, for which it may be substituted. A solution of it applied to the tongue causes a sensation of coldness, followed by irritation and constriction of the fauces, and allowed to remain in contact with the skin, it is apt to excite a papular and even a vesicular eruption, and, applied in powder slightly moistened or incorporated with lard, it may produce an eschar. In substance or solution applied to the broken skin it may cause toxic symptoms. Internally it has been fatal in doses of from 3 to 5 grains. The employment of this salt in photography has of late years greatly multiplied the number of cases of poisoning by its use. The symptoms produced by it in such cases are insensibility, muscular spasm or convulsion, a cold, clammy, and pale skin, glistening eyes and dilated pupils, stertorous breathing, fixed jaws, foam on the lips, feeble or insensible pulse of the heart and arteries, and death in convulsion or by asthenia. On examination, the body is rigid, the eyes bright, the cavities exhale the odor of hydrocyanic acid, the lungs are congested, the auricles may be full and the ventricles empty, the brain is engorged, and also the lining membrane of the stomach, which presents a dark-red color streaked by the darker veins. In a word, its effects are, as above stated, those of hydrocyanic acid. (Compare ACID. HYDROCYANICUM DILUTUM.) Cyanide of potassium is used chiefly as a topical application for the relief of *headaches* associated with dyspepsia or with imperfect menstruation, or such as are generally included under the term *sick headache*. It has also been employed internally, and it is asserted with remarkable success, in the treatment of acute articular *rheumatism*, but the testimony appears to us insufficient. This treatment is vaunted by Dr. Luton of Rheims (*Bull. de théér.*, lxxxviii. 1), who prescribed the cyanide in solution to the extent of nearly 2 grains (Gm. 0.10) in the course of a day, or in pills of 1 grain each (Gm. 0.06), one or two of which were administered within the same space of time. He states that he did not in any case exceed the daily quantity of $2\frac{1}{2}$ grains (Gm. 0.15), and, finding that it occasioned colic and vertigo, he resumed the smaller doses. If used internally at all, for which we can discover no necessity, it should not be prescribed at first in doses exceeding $\frac{1}{4}$ grain (Gm. 0.008). A solution of from 2 to 4 grains of the salt in an ounce of water may be applied as a lotion to the head and as the most rapid means of removing stains produced by *nitrate of silver*. It is, however, too dangerous an agent to be used without extreme caution. (For an example of its fatal use through mischance see *Edinb. Med. Jour.*, xxvii. 506.)

POTASSII ET SODII TARTRAS, U. S.—TARTRATE OF POTASSIUM AND SODIUM.

Soda tartarata, Br.; *Sodæ et potassæ tartras*, *Sodæ potassio-tartras*, *Tartarus natronatus*, P. G.; *Natro-kali tartaricum*, *Sal polychrestum Seignetti*, *Tartras potassico-sodicus*.—*Rochelle salt*, *Tartarated soda*, E.; *Sel de Seignette*, *Soude tartarisée*, Fr.; *Seignettesalz*, G.

Formula $\text{KNaC}_4\text{H}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$. Molecular weight 282.

Preparation.—Take of Carbonate of Sodium 12 ounces; Acid Tartrate of Potassium, in fine powder, 16 ounces; Boiling Water 4 pints (Imperial). Dissolve the carbonate of sodium in the water, add gradually the acid tartrate of potassium, and if, after

being boiled for a few minutes, the liquid has an acid or alkaline reaction, add a little carbonate or acid tartrate till a neutral solution is obtained. Boil and filter, concentrate the liquor till a pellicle forms on the surface, and set it aside to crystallize. More crystals may be obtained by again evaporating as before.—*Br.*

Since the molecular weight of bitartrate of potassium is 188, and $\frac{1}{2}$ molecule of crystallized sodium carbonate weighs 143, 16 parts of the former require $12\frac{1}{2}$ parts of the latter if both salts are chemically pure. Owing to the presence of calcium tartrate in the one, and the loss of water of crystallization by the other, the proportions required must vary somewhat with different samples of the commercial salts; but there is no difficulty in rendering the solution exactly neutral if the above directions are followed. The reaction between the two salts is explained by the equation $2KH_2C_4H_4O_6 + Na_2CO_3 = 2KNaC_4H_4O_6 + (CO_2 + H_2O)$; besides the double salt, water and carbonic acid are formed, the latter escaping with effervescence. It is advisable to keep the neutralized mixture for some time at a temperature of about 60° C. (140° F.), when much of the calcium tartrate will be deposited, and may be removed by filtration. Large and well-formed crystals are obtained if the solution is very slowly evaporated.

This double salt was first obtained in 1672 by Pierre Seignette, an apothecary of Rochelle in France, and was sold as a secret remedy. But in 1731 the process for obtaining it was communicated by Boulduc to the French Academy, and by C. J. Geoffroy to Sloane of London.

Properties.—Tartrate of potassium and sodium crystallizes in large perfectly transparent, inodorous, six- or eight-sided prisms, or more frequently half-prisms of the right rhombic order. If crystallized from a solution containing calcium tartrate, they are white and more or less opaque. In our commerce the salt is most generally met with in the state of white powder. It has a mild saline, faintly bitterish, and cooling taste, is slightly efflorescent in dry air, and dissolves at 11° C. (51.8° F.) in 2.4 parts, at 26° C. (78.8° F.) in 1.5 parts of water (Osann), and in all proportions of boiling water, but is nearly insoluble in alcohol. The salt melts in its water of crystallization when carefully heated to about 75° C. (167° F.), and after cooling remains liquid and soft for some time. By the heat of the water-bath it loses 19 per cent of water of crystallization, and at 130° C. (266° F.), or, according to Fresenius, near 215° C. (419° F.)—altogether 25.5 per cent. At a higher heat it is decomposed, gives off inflammable gases which have the odor of burnt sugar, and leaves charcoal which contains the carbonates of potassium and sodium, and imparts to a non-luminous flame a yellow color, appearing red when viewed through a blue glass. The concentrated aqueous solution yields, on the addition of hydrochloric or acetic acid, a crystalline precipitate of cream of tartar; with barium chloride, a white precipitate soluble in nitric acid; and with silver nitrate, a white precipitate, turning black on boiling.

Tests.—The solution in 10 parts of distilled water should be clear, of neutral reaction to test-paper, and should produce no precipitate or turbidity with ammonium oxalate (calcium salt) or with ammonium sulphide (metals); and when acidulated with nitric acid and filtered from the precipitated acid potassium tartrate, the clear solution should not be affected by barium chloride (sulphate), and yield merely an opalescence (cloudiness, *U. S.*) with silver nitrate. Although ammonia is not likely to be present in a salt having the above properties, the *U. S.* and *P. G.* direct testing for it with caustic potassa. The alkaline residue left from the incineration of 3.53 Gm. of the salt should require for complete neutralization not less than 25 Ccm. of the volumetric solution of oxalic acid (*U. S.*), or 141 grains of the salt 990 grain-measures of the solution (*Br.*).

Off. Prep.—*Pulvis effervescens compositus, U. S.*

Medical Action and Uses.—In doses of from half an ounce to an ounce (Gm. 16–32) it operates as a gentle and cooling laxative, and seldom disagrees with the stomach. It is particularly acceptable in *Seidlitz powders*, which form an effervescing draught. In small and repeated doses it renders the urine alkaline. It is not incompatible with tartar emetic, with which it has sometimes been used as an emeto-cathartic, and also, in small doses, as a febrifuge. It may be given as a purgative in doses of about 1 ounce (Gm. 32). As an antilithic, from 60 to 120 grains (Gm. 4–8) may be taken, largely diluted, several times a day.

FIG. 226.

Crystal of Rochelle Salt.

POTASSII FERROCYANIDUM, U. S., Br.—FERROCYANIDE OF POTASSIUM.

Potassæ prussias flava, Br.; *Kalium ferrocyanatum*, *Kalium borussicum*, *Cyanurctum ferroso-potassium*.—*Yellow prussiate of potash*, E.; *Prussiate jaune de potasse*, *Ferrocyanure de potassium*, Fr.; *Ferrocyankalium*, *Blutlaugensalz*, G.

Formula $K_4FeCy_6.3H_2O = K_4Fe(CN)_6.3H_2O$. Molecular weight 421.9.

Preparation.—This salt was discovered by Macquer (1752) in boiling Prussian blue with caustic potassa. The iron contained in it was for a long time supposed to be an impurity, even after Berthollet (1787) had shown it to be one of its essential constituents. The salt is now extensively prepared by heating in suitable iron vessels potash which is free from sulphate until it is melted, and introducing a mixture composed of 1 part of iron filings and 28 to 33 parts of charcoal obtained from blood, hoofs, horn, hides, leather, or similar animal substances rich in nitrogen. It is less advantageous to employ these substances in the uncharred condition. 100 parts of potash require about 75 or 80 parts of the charcoal or about 100 parts of the animal matter. An evolution of carbonic acid and inflammable gases takes place after each addition to the melted mass, and when the whole fuses quietly the "melt," as it is termed, is ladled out, cooled, dissolved in water, decanted from the sediment, and crystallized. Before it enters commerce it requires purification by recrystallization from water. The above quantities yield about 120 parts of melt and about 25 parts of crystallized ferrocyanide of potassium. The insoluble portion of the melt consists of charcoal, iron, iron sulphide, phosphate of calcium, and silica. This black residue is used as manure, and is said to be destructive to the larvæ of insects. The mother-liquors, which furnish no longer well-defined crystals, are evaporated and used in another operation; they contain the excess of potash employed; also potassium sulphocyanide in case the potash was contaminated with sulphate. Although this salt is extensively manufactured in the United States, 56,000 pounds of it were imported in the year 1878 and 544,167 pounds in 1881.

Properties.—Ferrocyanide of potassium crystallizes from water in large inodorous, lemon-yellow, four-sided tables or prisms, which are translucent and rather soft and friable, and, being crystallized on a cord, usually cohere in columnar masses. It has the specific gravity 1.83, a sweetish and saline taste, and dissolves with a yellow color in 4 parts of water at 15° C. (59° F.) and in 2 parts of hot water, the salt being precipitated from this solution by alcohol in pale-yellow, pearly scales. The salt is permanent at a low temperature, but near 50° C. (122° F.) it begins to lose water of crystallization, of which it contains 12.8 per cent., and it becomes anhydrous at 100° C. (212° F.), leaving a white friable mass which melts below red heat, and at a higher temperature is decomposed into nitrogen gas and a mixture of potassium cyanide and carbide of iron. Exposed to light in the presence of moisture, it is slowly decomposed, with the

FIG. 227.

Crystal of Potassium Ferrocyanide.

formation of Prussian blue. Its solution has a neutral reaction and produces a dark-blue precipitate with ferric salts, a bluish-white precipitate (becoming dark-blue in contact with air) with ferrous salts; a brown-red precipitate with salts of copper, and white precipitates with acetate of lead and corrosive sublimate; also a white crystalline precipitate with a saturated solution of sodium bitartrate. Heated with dilute sulphuric acid, hydrocyanic acid is given off. Alkalies fail to precipitate the iron from its solution, but on fusing the salt with potassium carbonate, cyanide of potassium is formed and metallic iron is separated.

Tests.—The concentrated solution of the salt should not effervesce on the addition of sulphuric acid (absence of carbonate), and when diluted with water and acidulated with hydrochloric acid should not produce a white precipitate with chloride of barium (absence of sulphate). Since nitrate of silver is precipitated white by ferrocyanide of potassium, the presence of chloride in the latter cannot be detected until after the salt has been decomposed by fusion with pure nitrate of ammonium, or by deflagration with an equal weight of pure potassium nitrate, when the solution of the residue, acidulated with nitric acid, should not give a curdy white precipitate with nitrate of silver. The U. S. Pharmacopœia permits the presence of a minute amount of sulphate and chloride.

Pharmaceutical Uses.—Ferrocyanide of potassium is used in the preparation of Acid. hydrocyan. dilut., U. S., Br., of cyanides, ferrocyanides, and of the following salts:

Allied Salts.—FERRICYANIDE OF FERRIDCYANIDE OF POTASSIUM, *Red prussiate of potash*: $K_3Fe_2Cy_{12}$. On passing chlorine gas into a cold solution of ferrocyanide of potassium the liquid changes in color from yellow to red. When it ceases to produce a blue precipitate or color with

ferric chloride it is concentrated and the crystals purified by recrystallization. The salt is in dark-red, transparent prisms, has a saline and slightly astringent taste, and dissolves in about 4 parts of cold water. On exposure to light the solution is readily altered, ferrocyanide being again produced, when it will yield a blue precipitate with ferric salt. The salt in its fresh solution is employed as a test, precipitating dark-blue with ferrous, red-brown with mercurous, brownish-yellow with cupric, and orange-colored with argentic salts. It yields no precipitates with ferric, mercuric, or lead salts. 12,287 pounds of this salt were imported in 1878, and 106,424 pounds in 1881.

POTASSIUM SULFOCYANATE (SULFOCYANIDE).—Sulfoeyanure de potassium, *Fr.*; Kaliumsulfoeyanat, *Rhodankalium*, *G.* Formula KSCN ; mol. weight 97.—It is prepared by melting together 17 parts of potassium carbonate, 32 parts of sulphur, and 46 parts of anhydrous potassium ferrocyanide, and heating to low redness; the cold mass is treated with boiling alcohol. The salt crystallizes in colorless, four-sided, striated prisms, which are inodorous, have a pungent and saline taste, are deliquescent on exposure, and dissolve readily in water and in alcohol. A solution of the salt is used as a test for ferric salts, with which it gives a blood-red color which is not discharged by hydrochloric acid (difference from acetates and formates), but disappears on the addition of corrosive sublimate (difference from meconates).

SODIUM NITRO-PRUSSIDE, $\text{Na}_3\text{Fe}(\text{CN})_6 \cdot 0.2\text{H}_2\text{O}$. It is prepared by digesting 1 part of potassium ferrocyanide with 2 parts of nitric acid and 2 parts of water, until the liquid ceases to produce a blue precipitate with iron salts. On cooling, potassium nitrate crystallizes, and the mother-liquor after neutralization with sodium carbonate yields colorless crystals of potassium nitrate and red ones of sodium nitro-prusside; the latter are recrystallized from water. The salt forms ruby-colored rhombic prisms which are permanent in the air and dissolve in $2\frac{1}{2}$ parts of cold water, the solution being decomposed by light. A fragment of the salt heated with an oxygenated volatile oil darkens the latter, often producing a characteristic color; this reaction is prevented by oil of turpentine. In alkaline solution it is a delicate test for sulphides, producing with them a violet or blue color.

Medical Action and Uses.—Ferrocyanide of potassium has been reputed, on very slender authority, to possess active medicinal properties, anodyne, sedative, and astringent. A thorough investigation of its action by Regnaud and Hayem led them to conclude that it is inoperative both as a chalybeate and a sedative, and that it may be administered for weeks in the daily *dose* of several grains without deranging the health or altering the composition of the urine. It is used only as a chemical test for iron, copper, and zinc.

POTASSII HYPOPHOSPHIS, *U. S.*—HYPOPHOSPHITE OF POTASSIUM.

Kalium hypophosphorosum, Hypophosphis potassiensis, kalicus.—*Hypophosphite de potasse*, *Fr.*; *Kaliumhypophosphit, Unterphosphorigsaures Kali*, *G.*

Formula KH_2PO_2 . Molecular weight 104.

Preparation.—This salt may be prepared in a manner similar to that by which hypophosphite of calcium (see page 352) is obtained. When a solution of potassa is boiled with phosphorus, hypophosphite of potassium is produced, which is freed from potassa by passing carbonic acid gas into the solution, evaporating, and dissolving the hypophosphite by alcohol. It is also yielded by the double decomposition of hypophosphite of calcium and carbonate of potassium, when carbonate of calcium is precipitated and hypophosphite of potassium remains in solution; $\text{Ca}_2\text{H}_2\text{PO}_2 + \text{K}_2\text{CO}_3$ yields $\text{CaCO}_3 + 2\text{KH}_2\text{PO}_2$.

Properties.—It may be obtained in hexagonal tabular crystals, but, being extremely deliquescent on exposure, it is usually seen in white, opaque, crystalline masses or as a white granular powder. It is inodorous, has a pungent saline and bitterish taste, and a neutral or faintly alkaline reaction, and is very freely soluble in water and diluted alcohol, less soluble in absolute alcohol, but insoluble in ether. "It dissolves in 0.6 part of water and in 7.3 parts of alcohol at 15°C . (59°F .), in 0.3 part of boiling water and in 3.6 parts of boiling alcohol."—*U. S.* Heated to redness when not in contact with air or in a long test-tube, it evolves easily inflammable phosphoretted hydrogen, burning with a white (bright-yellow, *U. S.*) flame. According to Rammelsberg (1872), the gas given off consists of hydrogen and phosphoretted hydrogen, and the residue of pyro-phosphate and metaphosphate of potassium. Heated in the air, the salt burns with a yellow flame, and when evaporated with nitric acid or tritreated or heated with oxidizing agents it detonates violently. When boiled with potassa, hydrogen is given off; phosphite, and, after the solution becomes more concentrated, phosphate, of potassium is formed. The solution yields with a saturated solution of sodium bitartrate a white crystalline precipitate of cream of tartar, and with nitrate of silver a white precipitate which rapidly turns brown and black, separating metallic silver; acidulated with hydrochloric acid, and gradually

added to solution of corrosive sublimate, it causes a white precipitate consisting of calomel, and on further addition a black precipitate of metallic mercury.

Tests.—The above reactions, in connection with the ready solubility in water and alcohol, prove the purity of the salt. The aqueous solution of the salt should not effervesce with acids (carbonate), should not be rendered turbid by lime-water (carbonate, phosphate), should not be precipitated by ammonium oxalate (calcium), and should remain clear or merely become slightly cloudy with test mixture of magnesium (phosphate). Acidulated with hydrochloric acid, it should not become cloudy with barium chloride (sulphate).

Off. Prep.—Syrupus hypophosphitum, *U. S.*

Medical Uses.—This preparation has been especially recommended in the treatment of *chronic bronchitis*, but there is no sufficient proof of its efficacy in that or in any other disease, either alone or associated with the other alkaline and earthy hypophosphites. The virtue of the “syrup of the hypophosphites” resides in the iron which is one of its components.

POTASSII IODIDUM, *U. S., Br.*—IODIDE OF POTASSIUM.

Kalium iodatum, *P. G.*; *Kali hydroiodicum*, *Ioduretum potassicum*, *s. kalicum*.—*Iodure de potassium*, *Fr.*; *Jodkalium*, *Gr.*

Formula KI . Molecular weight 165.6.

Preparation.—The process recommended in the *U. S. P.* 1870 is as follows: To a hot solution of 6 ounces of potassa in 3 pints of distilled water sufficient iodine (about 16 ounces) is gradually added until the liquid remains slightly colored from excess of iodine; the solution is concentrated, 2 ounces of powdered charcoal are stirred in, the mixture is evaporated to dryness, and the powder heated for 15 minutes to dull redness in an iron crucible; the salt is then dissolved in distilled water and crystallized.

The process of the *British Pharmacopœia* does not essentially differ from the preceding except in some of the details. 1 gallon (Imperial) of potassa solution and 21 ounces or a sufficiency of iodine are directed for the production of a permanent brown tint. The liquid is evaporated to dryness, the residue powdered, mixed intimately with 3 ounces of charcoal, and the mixture, in small quantities at a time, is thrown into a red-hot crucible. When the contents are fused they are poured out, and after cooling dissolved in 40 ounces of boiling distilled water, and the solution filtered and crystallized.

On dissolving iodine in solution of potassa a reaction takes place precisely analogous to that which occurs in the action of bromine or chlorine upon the same liquid. (See POTASSII BROMIDUM and POTASSII CHLORAS.) $6KHO$ and $3I_2$ yield $5KI + KIO_3 + 3H_2O$. The iodate of potassium may be separated by evaporating the solution to dryness and treating the residue with alcohol, which dissolves the iodide of potassium only; or it may be deprived of its oxygen, and thus be converted into iodide. The deoxidation may be effected in the solution by means of sulphuretted hydrogen, but some loss of iodine is then unavoidable, and the salt is apt to contain sulphur. The saline mass left on evaporation, when heated to redness gradually parts with its oxygen, but the reduction is effected at a lower temperature and more rapidly if the mass had been previously mixed with charcoal, starch, sugar, or similar organic matter. For effecting the mixing of the charcoal with the saline mass the first directions given above are very convenient, but for reducing the iodate it is best to operate as directed by the *British Pharmacopœia*. If the mixture in small quantities is thrown into a red-hot crucible, each portion deflagrates, carbonic oxide is given off, and iodide of potassium formed. The sudden evolution of the gas from a large quantity of the mixture heated together is likely to occasion loss. This reaction is explained by the equation $KIO_3 + C = KI + 3CO$.

Various other processes have been suggested, and are serviceable, more particularly for preparing potassium iodide on a limited scale. The following deserve to be mentioned: Iodine is converted into hydriodic acid by the action of sulphuretted hydrogen (see page 59), and the acid neutralized by carbonate of potassium. Or, iodide of iron is first prepared, and the green solution boiled with an equivalent quantity of carbonate of potassium, filtered from the oxide of iron, and evaporated. The iron will settle more rapidly if an additional quantity, equal to one-third of that used in preparing the solution of ferrous iodide, is added thereto before precipitation by potassa. Instead of potassa, Hesse recommends decomposing the solution by boiling with milk of lime; the filtrate is freed from excess of lime by carbonic acid gas, and the calcium iodide decomposed by a hot solution of potassium sulphate; the little calcium sulphate remaining in the filtrate is

decomposed by potassium carbonate, after which the clear solution is evaporated to dryness. Fuchs (1865) recommended prolonged digestion of 100 parts of iodine, 240 of water, 75 of potassium carbonate, and 30 of iron, until carbonic acid ceases to be given off; the solution is further concentrated, exposed in a warm place until all iron has been converted into ferric oxide, then dried, heated to incipient redness, and extracted with water.

Nearly all the potassium iodide consumed here is now manufactured in the United States. Only 50 pounds were imported in the year 1883.

Properties.—When entirely pure, iodide of potassium is in transparent colorless cubes of a neutral reaction. This is the salt directed by the U. S. P., but as generally met with it is crystallized from an alkaline solution, and the crystals are white and opaque or merely translucent, and have a slight alkaline reaction. Crystals of similar appearance are also obtained, according to Wittstein (1861), from neutral solutions at a somewhat elevated temperature, and, according to Erlenmeyer, from very concentrated solutions. Iodide of potassium has a slight peculiar odor, a pungent saline afterward bitterish taste, melts below a red heat (Gay-Lussac), and congeals on cooling to a pearly mass. On melting the salt in contact with air a trace of iodate is formed, a little iodine given off, and the mass acquires an alkaline reaction (Pettersen, 1870); at a bright-red heat the salt is slowly volatilized. It is permanent in the air, but in a damp atmosphere or when of an alkaline reaction is somewhat deliquescent. It is freely soluble in water, requiring, according to Mulder (1864), at 15° C. (59° F.) 0.714, at 30° C. (86° F.) 0.657, at 60° C. (140° F.), 0.57, and at 100° C. (212° F.), 0.48 part of this solvent. It is likewise soluble in alcohol, requiring at the ordinary temperature 40 parts of absolute alcohol, 16 parts of alcohol sp. gr. .835, 8 parts of alcohol sp. gr. .850, and 1½ parts of diluted alcohol. The salt dissolves in about one-half the quantities named of boiling alcohol, and on cooling crystallizes partly in needles. The aqueous solution yields with tartaric acid or with sodium bitartrate a white crystalline precipitate of potassium bitartrate, and with a few drops of chlorine-water liberates iodine, which is recognized by the blue color it imparts to starch-paste or by the violet color of its solution in chloroform or bisulphide of carbon. On exposure to sunlight the solutions of iodide of potassium acquire a yellow or brownish color from the liberation of iodine, the decomposition being due to the influence of ozone, according to Houzeau (1858), or to the presence of carbonic or other acid, according to Bastaudier (1876). The experiments of Papasogli (1881) prove that sunlight, both diffuse and direct, does not decompose pure potassium iodide or its mixture with iodate; but carbonic anhydride liberates from the mixture a small quantity of iodine, while at low temperatures it has no effect upon either one of the pure salts, yet at high temperatures separates hydriodic acid in solutions of the pure iodide. Strong mineral acids liberate from the salt hydriodic acid and iodine. A mixture of the salt with chloride of ammonium becomes moist and brown on exposure, and when heated is decomposed, chloride and iodide of potassium being left behind. Raup observed that 100 parts of the iodide dissolved in 200 parts of water will dissolve 153 parts or 2 atoms of iodine, forming a dark-red liquid, from which water throws down a portion of the iodine. If the salt is dissolved in about thirty times its weight of water, the solution takes up 1 atom of iodine. These solutions are completely decolorized when agitated with ether, chloroform, or bisulphide of carbon; but if the solution has been made with alcohol instead of water, carbon bisulphide fails to extract the iodine, although this element is removed by the solvent mentioned from the simple tincture of iodine (Jørgensen, 1870). An aqueous solution of iodine in iodide of potassium produces with subacetate of lead dark-colored precipitates, which Dossios and Weith (1869) regarded as being mixtures of iodide of lead with finely-divided iodine; but Piffard (1861) found the precipitate with acetate of lead, after drying, could be heated to 71° C. (159.8° F.) without evolving iodine, which could likewise not be extracted with simple solvents. These facts, it seems, point to the existence of compounds of 1 atom of potassium with 1, 2, and 3 atoms of iodine. (See also LIQUOR IODINII COMP. and TINCTURA IODINII COMP.)

Tests.—If impurities other than bromide and chloride are present, the large cubical crystals will usually be the purest; for the following tests it is therefore advisable to triturate together crystals of different size: A little of the powdered salt taken up with the loop of a platinum wire and held in a non-luminous flame should at once impart a violet color to the latter (absence of sodium salt). Single crystals or several fragments of crystals laid for a moment upon moistened (not wet) red litmus-paper should not at once produce violet-blue stains (limit of potassium carbonate, about 0.1 per cent.). The aqueous solution should not be colored dark or rendered turbid by hydrosulphuric acid

(metals). An aqueous solution of the salt, mixed with a little gelatinized starch, should not become blue on being added to a mixture of diluted hydrochloric acid and test zinc (nitrate). Iodine is also liberated by this test in the presence of iodate, but the absence of the latter salt is recognized by adding gelatinized starch to the aqueous solution of the salt, and afterward a dilute acid (sulphuric, hydrochloric, or tartaric, but not nitric), when a blue color should not at once be developed. "0.2 Gm. of the salt dissolved in 2 Ccm. of ammonia-water, and then agitated with 13 Ccm. of volumetric solution of silver nitrate, should yield a filtrate which on being acidulated with nitric acid should not become so turbid within 10 minutes as to lose its pellucidness."—*P. G.* This test proves the absence of more than about 1 per cent. of chloride and bromide. It has also been admitted by the U. S. P., where, however, five times the quantity of material is ordered, and where it is required that in the acidulated filtrate *no* cloudiness should make its appearance within 10 minutes; which excludes even traces of chloride and bromide. Silver iodide is also slightly soluble in (about 3000 parts of) ammonia-water. "A solution of 1 Gm. of the salt in 20 Ccm. of water, mixed with 5 or 6 drops of test solution of barium nitrate, should show no immediate cloudiness or precipitate."—*U. S.* This test admits the presence of a trace of sulphate, which is excluded by the *P. G.* (the solution mixed with 10 drops of solution of barium nitrate should not be turbid in 5 minutes). Cyanide may be present from using impure potassium carbonate or impure iodine; its presence is determined by adding to a solution of the iodide a little ferrous sulphate, a drop of solution of ferric chloride or sulphate, and a slight excess of solution of soda. On warming the mixture and acidulating it with hydrochloric acid a blue color (of Prussian blue) should not be produced. "1 Gm. requires for complete precipitation 60.2 Ccm. (60.387 Ccm. for the pure salt) of the volumetric solution of silver nitrate."—*Br.*

Carbonate, sulphate, iodate, nitrate, and cyanide of potassium are insoluble in strong alcohol, which dissolves only small quantities of bromide and chloride of potassium. An adulteration of the iodide with more than mere traces of the last two salts may be detected by treating the iodide with eighteen times its weight of warm alcohol, and, after cooling, testing the undissolved portion. These admixtures may be estimated from the silver precipitate, which from 10 grains of pure iodide of potassium weighs 14.15 grains (or 1.415 Gm. from 1 Gm. of the salt), from the same quantity of bromide 15.8, from chloride 19.2 grains, and from cyanide 20.57 grains. Moreover, the last three may be extracted from the former by ammonia, and, after acidulating this solution with nitric acid, collected and weighed separately; or, instead of dissolving it in water, the salt to be tested may be dissolved in ammonia-water, when on the addition of silver nitrate only iodide of silver will be thrown down.

Pharmaceutical Uses.—Iodide of potassium is used in preparing the iodides of lead and of mercury. It is an ingredient of *Linim. iodi*, *Linim. potass. iodidi cum sapone*, *Br.*; *Liquor iodi comp. (iodi)*, *Tinct. iodi comp.*, *Unguentum iodi*, *Ung. potassi iodidi*, *U. S.*, *Br.*

POTASSII IODAS.—Iodate of potassium, *E.*: Iodate de potasse, *Fr.*: Kaliumjodat. Jodsaures Kali. *G.* KIO_3 ; molecular weight 214.—This salt is left behind on treating the product of the reaction of iodine upon potassa with alcohol; or it may be prepared, according to L. Henry (1870), by diffusing 127 parts of iodine in cold water, passing chlorine into it until chloride of iodine, ICl , has been formed and dissolved in water, adding 122.5 parts of chlorate of potassium and heating, when chlorine gas will be evolved, and iodate of potassium crystallizes on cooling; $\text{ICl} + \text{KClO}_3$ yields $\text{KIO}_3 + \text{Cl}_2$. The salt crystallizes in translucent or milk-white cubes, dissolves in 13 parts of cold and in 3.1 parts of boiling water, and is more freely soluble in solution of potassium iodide and insoluble in alcohol. When heated, the salt fuses, and at a high temperature parts with its oxygen, leaving potassium iodide. It detonates, but less violently than the chlorate, when thrown upon burning coal. On the addition of arsenious acid or stannous chloride the solution separates iodine; if not too diluted, its solution yields white granular precipitates with salts of barium, lead, and silver.

Physiological Action.—By the stomach, and given in large doses to animals, iodide of potassium causes efforts at vomiting, and if this is prevented by ligature they suffer depression, accompanied by diuresis, and followed by spasms and death. The mucous membrane is vascular, soft, and ulcerated. Injected into the veins, it also causes convulsions and speedy death. In man it is very rapidly absorbed and eliminated by all the excretories without undergoing decomposition, but it is discharged mainly through the kidneys, for nearly nine-tenths of the amount used may be recovered from the urine. The elimination is not always rapid, for in some cases the salt may be detected in the urine several weeks after it was taken. It has no uniform influence on either the amount or the quality of the urine secreted, but sometimes occasions albuminuria. The continued use

of iodide of potassium excites eruptions of the skin, the most common of which is acne indurata. More rarely blood-blisters or watery blebs form. Cases are sometimes met with in which the smallest dose of the salt excites urticaria (*Phila. Med. Times*, xi. 672). Iodic purpura occurs in the form of discrete purple spots upon the skin, most frequently of the legs, and which usually disappear spontaneously in two or three weeks. (Compare Mackenzie, *Times and Gaz.*, May, 1879, p. 501.) The pustular and bullar forms of the eruption seem to take their origin in the hair-follicles according to some dermatologists, in the sebaceous glands according to others. The blebs are sometimes very large, measuring an inch or more in diameter, and are filled with a clear, turbid, or bloody serum, and have been described under the name *hydroa*. They are very painful to the touch. They are of rare occurrence, and seem to depend upon some peculiarity of the patient, since they may be produced by very small doses of the medicine. In one case an attack of hemiplegia occurred during the use of massive doses of the iodide (Hallopeau). Iodide of potassium is apt to cause salivation, much resembling that which occurs during pregnancy. The symptom is mild, is not accompanied with the fetor of mercurial salivation, and ceases when the medicine is suspended. A familiar effect produced by the salt is a coryza with lachrymation and a congested state of the eyes, nostrils, frontal sinuses, antrum Highmorianum, and throat: more rarely the larynx exhibits catarrhal symptoms, with hoarseness, obstruction, and harassing cough, and sometimes very moderate doses have caused fulness of the head, giddiness, and trembling of the legs in walking. Sometimes, also, there has been impairment of vision and articulation and a partial paralysis of the vocal organs. These effects are often produced by a prolonged use of very small doses, but sometimes very large doses, such as 40 or 60 grains a day, may be taken for weeks without causing any special phenomena. The addition of aromatic spirit of ammonia to a solution of the iodide is said to greatly diminish the tendency to such consequences as have been now described. After a single dose of 8 grains of this iodide the mouth and throat became swollen and secreted viscid mucus and saliva; oedema affected not only the face, but gradually extended to the nostrils and throat and to the whole body; respiration was embarrassed. The symptoms were much relieved by the hypodermic injection of morphia, but did not disappear for several days (*Boston Med. and Surg. Jour.*, Oct. 1882, p. 405). In rare cases iodide of potassium produces an effect which is not so unusual after the prolonged administration of iodine—atrophy of the testicles.

Medical Uses.—Iodide of potassium, although sometimes successful, is not as efficacious as iodine in relieving *mercurial sore mouth*; indeed, it often aggravates the local affection. At the same time, it is the most effectual means of *eliminating mercury* from the system, and thereby curing paralysis, neuralgia, and other symptoms which occur in chronic poisoning by this metal. The same is true of *lead-poisoning* in its chronic form. If the iodide be given to a person by whom lead or mercury has been taken for a considerable period without producing characteristic toxic symptoms, those symptoms will presently be manifested in consequence of the liberation of the metal by the salt, and at the same time the former may be detected in the urine, and sometimes in the saliva, by appropriate chemical tests. To prevent a renewal of the poisoning under this treatment the iodide must be cautiously administered. According to Pouchet, during the period of aggravated symptoms the urine contains on an average 1 Mgm. of metallic lead to the liter. Under the influence of from 4 to 6 grains daily of potassium iodide the elimination of lead increases greatly for a week or ten days, and then declines below its original quantity. Hence, according to Pouchet, the remedy should not be administered continuously (*Boston Med. and Surg. Jour.*, Aug. 1881, p. 125). The power of the iodide to combine with mercury already in the system is illustrated in the treatment of *constitutional syphilis*—*i. e.* of the skin, cellular tissue, bones, and nervous system—by this medicine in persons who had taken mercury during the earlier stages of the disease. It is not unusual for them to experience the full effects of mercurial salivation. Three different explanations have been proposed for the cure of constitutional syphilis by the iodide of potassium: 1, that it revives the mercury in the system and enables it to work its specific cure; 2, that it eliminates the mercury from the system, and so removes an obstacle to the cure; and 3, that it cures syphilis by its intrinsic powers. These propositions are not incompatible with one another, and each may, in individual cases, be true. Clinical observation renders it probable that such is the case. The successful use of the iodide in this disease depends greatly upon its dose, which should never be less than 10 grains three times a day, and often must be twice or thrice as much. Indeed, not a few experts in the treatment of syphilis maintain that unless very large doses of the iodide

are given, so as to saturate the system with it, its best effects will not be displayed. In one case the patient seems to have been rescued from an apparently hopeless condition by taking 300 grains of the salt daily for three weeks (Henry, *New York Med. Record*, xx, 590). The eliminative operation of this salt is also shown in chronic *arsenical poisoning* (Falek, *Toxicologie*); a striking illustration of it was presented by the case of an arsenic-eater in Philadelphia (Da Costa, *Phila. Med. Times*, xi, 385).

The value of iodide of potassium in the treatment of *aneurism of the aorta* was discovered, as that of all really valuable medicines has been, "by the merest hazard;" and although the method which some have pursued in employing it included the absolute and prolonged repose of the patient, the share of the iodide in the result cannot fairly be challenged. In cases of aneurism of the aortic arch "not only has relief of neuralgic pains and of the general distress followed its administration, but the local-pressure symptoms have been mitigated, and firm thrombosis has taken place within the sac, while the area of pulsation and of percussion-dulness has exhibited sensible reduction" (Walshe). More recently Balfour (1868) and Bramwell (1878) proved, the former by reports of fifteen, and the latter of seven cases, that this medicine, continuously given while the patient remains at absolute rest in bed and uses a non-stimulating diet, has caused a complete disappearance of all the active signs of an aneurismal tumor, and rendered possible a return to an industrious life. In 1882 a case of cure of aneurism of the aorta by this salt, given in daily doses of 75 or 80 grains and continued for several weeks, was reported by Rhett (*Med. News*, xli, 429). It is not said whether rest was conjoined or not. The medicine must be given in doses ranging from 20 to 30 grains (Gm. 1.33-2) thrice daily, and, with occasional intermissions when iodism occurs, should be continued for weeks or months.

Numerous cases of *dropsy* owe their cure to this medicine, including ascites due to splenic or hepatic induration, and hydrothorax depending upon cardiac obstruction. It has cured acute hydrocephalus from *granular meningitis*, but chiefly when mercury had been previously administered, and *chronic hydrocephalus* under similar circumstances. In these intractable diseases it should never be neglected; and in regard to tubercular or granular meningitis, which so rarely recovers under any treatment, the use of mercury followed by iodide of potassium cannot be too strongly recommended. In not a few cases also presenting signs of *tumor of the brain*, whether syphilitic or not, the symptoms have been greatly mitigated, and sometimes quite removed, by this medicine. Seguin insisted on the necessity of administering very large doses in all such cases (*Med. Record*, xxi, 50).

In the various forms of *muscular rheumatism* iodide of potassium is one of the most efficient remedies, but especially in acute lumbago, which it often cures with marvellous rapidity. In *sciatica* and other forms of rheumatic neuralgia it is sometimes of great advantage, and even in *angina pectoris* it may afford relief. It is worse than useless in acute *articular rheumatism*, but in the chronic disease, with thickening of the fibrous capsules of the joints and effusion within them, it is often the most efficient remedy. It need not, however, be given in large doses for this affection, nor for *chronic gout*, in which also it has been found of service, but its use must be long maintained. In *chronic bronchitis* with asthma, depending upon dilatation of the bronchia or upon thickening of their walls, the iodide is often signally beneficial. The paroxysmal affection is then subordinate to the lesion of nutrition. Sée (1878) referred to twenty-four cases of "*asthma*" which he treated with this medicine and either entirely cured or materially relieved. He gave daily from 20 to 45 grains (Gm. 1.25-3) in divided doses, and continued them for several weeks. In 1882 the same physician renewed the expression of his confidence in the medicine, calling it "the remedy *par excellence* for asthma," and yet stating that it is the most useful remedy for dyspnoea of cardiac origin. He admitted that if the treatment was too prolonged the patients were apt to suffer from bloody extravasations in the mouth and nostrils, or even pulmonary hæmorrhage when a tuberculous diathesis existed, loss of appetite and aversion to food, emaciation, atrophy of the mammae, etc. A close scrutiny of this author's cases, so far as he describes them, and of several other cases published to confirm them, renders it more than probable that they were asthmatic only in so far as they complicated chronic bronchitis, a disease which the iodide of potassium has often cured. It is worthy of notice that Casey (1866) reported his having employed this medicine in twenty-five or thirty cases of "*asthma*," in every instance with decided and unequivocal relief. But the dose prescribed by him was only from 2 to 5 grains. The incongruity between the methods of the French and American physicians is very remarkable in view of the apparent identity of their results. More rational, and

probably much more efficient, than administering iodide of potassium by the stomach in large or in small doses for the relief of asthmatic bronchitis is the inhalation of an atomized solution of the salt of the strength of 5 per cent. The inhalation should be frequently repeated (Everard). On the whole, we do not find any reason for believing that asthma, in its proper sense, has been cured by iodide of potassium. In cases of *paralysis* due probably to pressure upon a motor centre or upon a nervous trunk, produced by syphilitic or other swellings, the medicine is often singularly efficient, and should never be omitted from the treatment. The same remark applies to many cases of spinal paralysis, and especially to those of incoördination of movements due to *sclerosis of the cord*. (Compare Mitchell, *Philad. Med. Times*, x. 422.) In all of the affections mentioned in this paragraph it is probable that the iodide is operative by its causing the absorption of indurations which compress the source or the channels of nervous power. That it restrains nutrition generally, normal as well as abnormal, is shown by its emaciating operation upon the testes, mammae, and ultimately on other organs, and that it at the same time promotes elimination is rendered probable by the history of its use in diseases of the skin and constitutional syphilis, etc.

The *dose* of iodide of potassium cannot be accurately defined; according to the object to be attained, it should be given in small doses, as 2 or 3 grains (Gm. 0.12–0.20), or very large ones, as from 10 to 20 grains (Gm. 0.60–1.30), three times a day, and always in a large quantity of liquid. It should be remembered that water dissolves more than its own weight of this salt. Its unpleasant taste is best concealed by dissolving it in carbonic acid water or in artificial Vichy water. This medicine has been used hypodermically in certain cases of its intolerance by the stomach, 8 grains being administered at each injection. According to Rabuteau, sulphate of quinine should not be administered before or after iodide of potassium, for mutual decomposition of the two medicines takes place and iodine is liberated, which may act poisonously.

POTASSII NITRAS, U. S., Br.—NITRATE OF POTASSIUM.

Potassæ nitras, Br.; *Kalium nitricum*, P. G.; *Nitrum depuratum*, *Sal petra*, *Sal nitri*, *Nitras potassicus s. kalius*.—*Nitrate of potash*, *Nitre*, *Saltpetre*, E.; *Azotate (Nitrate) de potasse*, *Nitre prismatique*, *Salpêtre*, Fr.; *Kaliumnitrat*, *Salpetersaures Kali*, *Salpeter*, *Kalisalpeter*, G.

Formula KNO_3 . Molecular weight 101.

Origin and Preparation.—*Nitrum* of the Romans was alkali carbonate, that of sodium being chiefly thus designated. *Saltpetre* was known to Geber in the eighth century, and in the Latin translations of his writings is called *sal petrae* and *sal petrosum*. Subsequently, it was distinguished as *sal nitrum* or *sal nitri*, until at the close of the sixteenth century it was called *nitrum*. (See *SODII CARBONAS*.) Fused by itself or with the addition of a small quantity of sulphur, it was formerly used as *sal prunelle* or *nitrum tabulatum*. *Saltpetre* is produced near the surface of the earth wherever nitrogenous organic substances are undergoing decomposition in the presence of air, moisture, and potassium compounds. It is present in considerable quantities in the calcareous soil near dwellings of some parts of India. This soil becomes impregnated with urine, and after it has been exhausted of its soluble salts soon generates them again, the decomposition being hastened by the hot and moist climate. In several parts of Europe nitrates are formed in a precisely analogous manner, either by collecting the urine of domestic animals in ditches which have been previously filled with a porous calcareous earth, or by mixing in the so-called *saltpetre-beds* animal and vegetable substances with wood-ashes and marl or other material containing lime, and forming this mixture into mounds which are occasionally moistened with drainings from the dung-pit, until after two or three years the salt accumulates in the outer layer of the heap, which is then removed, lixiviated with water, and left in contact with wood-ashes in order to decompose the nitrates of calcium and magnesium which are usually present. In India, which furnishes the greater part of the nitre, the process of exhausting the earth is very similar, except that it is usually packed upon wood-ashes and the whole lixiviated.

In the Mammoth Cave of Kentucky, and in other localities of the United States, *saltpetre* has occasionally been procured, and it may be obtained in variable quantities from most soils where vegetable and animal materials have been decaying, and from which it is taken up by the plants growing there, some of which are very rich in this salt. A. Boutin (1874) ascertained that *Amarantus melancholicus ruber* contains 16, and *Am.*

atropurpureus even 22.77, per cent. of potassium nitrate, calculated for the dry herb. The same salt crystallizes in some old extracts.

Since the Stassfurt mines have been worked the large quantities of chloride of potassium obtained have also been utilized in the production of saltpetre by a process of mutual decomposition effected with native nitrate of sodium (Chili saltpetre). Equivalent quantities of the two salts are boiled together with water until the chloride of sodium commences to separate in the boiling liquor, which is then concentrated and the chloride removed as it crystallizes. On the cooling of the solutions the crystallization of the nitre is usually disturbed by frequent stirring in order to better drain off the mother-liquor, in which most of the foreign salts remain dissolved. Variable quantities of these salts, and particularly of sodium and potassium chlorides, are always found in crude nitre, which for further purification is redissolved in water and granulated by evaporation and stirring. The last portions of adhering chlorides are in some places removed by percolating the granular powder with a concentrated solution of nitre, in which they are dissolved, while the nitrate is recovered by boiling the solution and removing the sodium chloride as it separates.

Most of the saltpetre used in the United States is purified here from the foreign crude article, of which during the year 1881-82 11,796,091 pounds were imported, besides 453,794 pounds of refined and partly refined nitrate of potassium.

Properties.—Nitrate of potassium crystallizes in colorless, transparent, six-sided, striated prisms of the rhombic system, which frequently have cavities in the interior filled with mother-liquor, so that on trituration they yield a damp powder. It is often kept in the granulated state, and is then a white crystalline powder. When heated to 339° C. (642.2° F.) it fuses to a colorless liquid, and congeals again on cooling to a radiating crystalline mass; in the presence of even a small proportion of chloride of sodium the radiating arrangement is less distinct, at least in the centre of the mass, or entirely wanting. At a higher temperature it gives off oxygen, and afterward oxygen and nitrogen, being gradually converted into nitrite, oxide, and peroxide of potassium; on the addition of sulphuric acid this residue gives off nitrous vapors. Potassium nitrate is neutral to test-paper, inodorous, has a pungently saline and cooling taste, and dissolves in water with a marked diminution of temperature. 1 part of the salt dissolves

at 0°	15°	30°	40°	50°	60°	80°	100°	114.1° C.
in 7.25	3.85	2.25	1.563	1.163	.901	.582	.405	.306 parts of water,

FIG. 228.

Crystal of Potassii Nitræs.

the boiling-point of the most concentrated solution being 114.1° C. (237.4° F.). The salt is insoluble in absolute and sparingly soluble in dilute alcohol. It is permanent in the air, but, according to Mulder (1864), absorbs a considerable amount of water when kept in a confined atmosphere saturated with moisture. When thrown upon red-hot coal it deflagrates. Warned with sulphuric acid and copper, it evolves red nitrous vapors; its aqueous solution gives a white crystalline precipitate of cream of tartar on the addition of a concentrated solution of tartaric acid or of sodium bitartrate, and if acidulated with hydrochloric acid yields a yellow precipitate with perchloride of platinum. The solution, mixed with an equal bulk of sulphuric acid, and afterward with ferrous sulphate, acquires a brown-black color.

Tests.—The aqueous solution of the salt should have a neutral reaction, and should not be affected by hydrosulphuric acid or sulphide of ammonium (absence of metals), chloride of barium (absence of sulphate), nitrate of silver (chloride), carbonate of ammonium (calcium salt), or after the addition of carbonate of ammonium by phosphate of ammonium (magnesium salt). The U. S. P. permits a faint opalescence with silver nitrate. On mixing the powdered salt or its concentrated solution with alcohol, and igniting the latter, the flame should have a violet but not a yellow color (sodium salt). On mixing 1 Gm. of the dry salt with 1 Gm. of sulphuric acid, evaporating to dryness, and igniting, the residue consists of sulphate of potassium, and should weigh .86 Gm. In the presence of nitrate of sodium the weight is less.

PULVIS TEMPERANS, S. PULVIS REFRIGERANS. Mix by trituration nitrate of potassium 1 part, bitartrate of potassium 3 parts; and sugar 8 parts.—*P. G.* 1872.

An older formula directs equal weights of sulphate and nitrate of potassium, and this, mixed

with 10 per cent. of vermillion, is *PULVIS TEMPERANS (RUBER) STAHLII*: Poudre tempérante de Stahl, *F. Cod.*

Physiological Action.—*On Animals*: In large but non-lethal doses a solution of nitrate of potassium thrown into a vein increases the arterial blood-pressure and reduces the frequency of the pulse. In lethal doses it causes a rapid fall in the arterial blood-pressure and the pulse-rate, and death by syncope is preceded by epileptiform convulsions. It appears to act as a sedative poison on the heart-muscle as well as upon the cardiac nerves. In small doses it reduces the pulse-rate and lowers the temperature, but the latter effect is more persistent than the former. In the composition and condition of the blood no change takes place, unless the use of the salt be greatly prolonged, and then the coagulability of the blood is impaired. Injected into a vein near the heart, it arrests the action of that organ, and injected into an artery supplying a limb, it first of all paralyzes the muscles with which it comes primarily into contact.

On Man: The action of nitrate of potassium upon man does not differ essentially from its action upon the lower animals. In small doses it is diuretic, provided it be given in an abundant watery vehicle; in large doses it is a cardiac and nervous sedative and a purgative; and in excessive doses a local irritant poison, as well as a powerful sedative of all the vital functions. A small piece of the salt dissolved in the mouth occasions a sense of coolness in the part and a saline taste; given in small and repeated doses to healthy persons, it does not clearly affect any function, although in some cases it appears to augment the secretion of urine, which is probably due to its local irritant action upon the kidneys, since a large proportion of it is eliminated, unchanged, with the urine. When large doses of the salt are given, however, this secretion is diminished and its specific gravity raised, chiefly by the nitre eliminated with it.

After large but non-poisonous doses the following symptoms have been observed: general weakness, giddiness, confusion of ideas, and indisposition to mental and bodily exertion, weakness of the lower limbs especially, low spirits, a tendency to grow fatigued and to sleep, timidity, and a slow and weak pulse. The pulse may fall at last to 20 per minute, and continue at the same rate for seven or eight days after the medicine has been discontinued. Appetite and digestion are not usually impaired, and the bowels are only occasionally loose. As a rule, however, full medicinal doses do not tend to relax the bowels. The effects upon the pulse and nervous system are among those which have led to the recognition of a close analogy between the salt under consideration and the bromide of potassium, and to the extraordinary suggestion that the potassium in the latter compound is the real source of its soporific powers!

When poisonous doses of nitre are taken, as an ounce and upward, there are symptoms of gastro-intestinal inflammation, and sometimes blood is vomited and passed by stool; the urine is diminished or suppressed; there are coldness of the extremities, a feeble and thready pulse, slow respiration, great debility, tremulousness, insensibility, blindness, deafness, and even convulsions. A case is on record in which a person who had taken 3½ ounces of nitre presented no marked symptoms at first, but at the end of 5 hours suddenly fell from his chair and expired. It is remarkable that poisoning by this substance generally ends in recovery, although for some time the patient may suffer from irritability of the stomach, colic, dysuria, and a sense of chilliness in the back and limbs, with weakness of the latter. After death a florid color of the lips has been noted, and a similar hue of the blood, which, indeed, other salts, as chloride of sodium, chloride of magnesium, etc., produce; the stomach is apt to contain blood, and its lining membrane is injected, softened, or corroded. The upper part of the small intestine may present a similar condition.

Medical Uses.—Nitre has long been used in acute *rheumatism*, given in a large amount of water or other liquid diluent, as 2 or 3 drachms (℥m. 8–12), and from that to an ounce (℥m. 32), in about a quart of water, which quantity was taken in 24 hours. There is no lack of competent authorities who declare that it subdues the fever and pain and shortens the attack, while others of equal competency allege that it is useless therapeutically, and repulsive to the taste and stomach. We have no doubt that the latter is the truer judgment of the two. At the present day this method of treatment is hardly thought of in the acute, and still less in the chronic, form of rheumatism. The same remark applies to *pneumonia*, various *fevers*, etc., and even in *dropsy* the diuretic virtues of nitre are too uncertain to entitle it to any confidence. It has been claimed as a remedy for *scorvy* on theoretical and unsubstantial grounds, and also upon the ground of its efficacy when dissolved in vinegar, without due consideration of the well-established virtues of the solvent in this disease. In *spasmodic asthma*, whether complicated with

bronchitis or not, inhalation of the fumes of burning paper impregnated with nitre renders the breathing freer and less stridulous, and sometimes, by repetition, cures the disease. The fumes may be employed by diffusion through the air of the patient's bedroom, or inhaled from a cigarette or from thin linen paper impregnated with a solution of nitre burned under a funnel, from the mouth of which the patient inspires. Powdered nitre, moistened with water and applied to the face night and morning, is one of the best remedies for *freckles* (*lentigo*). A similar solution is useful in *bruises* and *abrasions*. Nitre may be prescribed in powder in doses of from 10 to 30 grains (Gr. 0.60–2) or more, or in solution, which is preferable. The effects of an overdose of nitre are best palliated by the free use of water or of some bland liquid, and by warm narcotic fomentations of the epigastrium.

Potassium nitrite has been supposed to possess the powers of amyl nitrite, because their physiological action is very similar. But Dr. Hinsdale (*Inaug. Thesis*, Univ. of Penna., 1881) found that it aggravated the paroxysms of *epilepsy* and rendered them more frequent. As an antidote to strychnia he concluded that it displayed no power whatever.

POTASSII PERMANGANAS, U. S., Br.—PERMANGANATE OF POTASSIUM.

Potassæ permanganas, Br.; *Kalium permanganicum*, P. G.; *Kali hypermanganicum crystallisatum*, *Hypermanganas potassicus*, s. *kalicus*.—*Permanganate of potash*, E.; *Permanganate de potasse*, Fr.; *Kaliumpermanganat*, *Uebermangansaures Kali*, G.

Formula $K_2Mn_2O_8$. Molecular weight 314.

Permanganate of potassium should be kept in well-stopped bottles, and should not be triturated nor combined in solution with organic or readily oxidizable substances.—U. S.

Origin.—This salt appears to have been obtained by Glauber (1659), who by melting together magnesia (black oxide of manganese) with fixed alkali (potash), and dissolving the mass in water, found the solution to be of a purple color and to change to blue, red, and green. Chevillot and Edwards (1817) showed that for the production of this colored compound the presence of oxygen was necessary, whereby the manganese was oxidized to an acid. Forehammer (1820) distinguished in the green and red compound two acids, the composition of which was determined by Mitscherlich (1830).

Preparation.—Take of Caustic Potash 5 ounces; Black Oxide of Manganese, in fine powder, 4 ounces; Chlorate of Potassium $3\frac{1}{2}$ ounces; Carbonic Acid a sufficiency; Distilled Water $2\frac{1}{2}$ pints. Reduce the chlorate of potash to fine powder, and mix it with the oxide of manganese; put the mixture into a porcelain basin and add to it the caustic potash, previously dissolved in 4 ounces of the water. Evaporate to dryness on a sand-bath, stirring diligently to prevent spurning. Pulverize the mass, put it into a covered Hessian or Cornish crucible, and expose it to a dull red heat for an hour, or till it has assumed the condition of a semi-fused mass. Let it cool, pulverize it, and boil with $1\frac{1}{2}$ pints of the water. Let the insoluble matter subside, decant the fluid, boil again with $\frac{1}{2}$ pint of the water, again decant, saturate the united liquors with carbonic acid, and evaporate till a pellicle forms. Set aside to cool and crystallize. Drain the crystalline mass, boil it in 6 ounces of the water, and strain through a funnel the throat of which is lightly obstructed by a little asbestos. Let the fluid cool and crystallize, drain the crystals, and dry them by placing them under a bell-jar over a vessel containing sulphuric acid.—Br.

When binoxide of manganese is heated to dull redness with an excess of potassa a portion of it is oxidized to manganic acid at the expense of a part of the oxygen of another portion of the binoxide, which is thereby reduced to manganic oxide. But if oxygen is at the same time conducted into the mass, all the manganese will be converted into manganic acid, which unites with the potassa, forming potassium manganate. It is more convenient to supply oxygen by means of an oxidizing agent, such as nitrate or chlorate of potassium, the former of which will supply an additional quantity of alkali for uniting with the manganic acid, while the latter will be converted into potassium chloride, which remains mixed with the manganate. In this case the result will be explained by the equation $6KHO + 3MnO_2 + KClO_3 = 3K_2MnO_4 + KCl + 3H_2O$. The proportions adopted by the British Pharmacopœia are those of Gregory, and refer to a nearly pure binoxide of manganese. If the article to be used should not contain at least 93 per cent. of MnO_2 , a correspondingly larger quantity should be employed. The ignited mass contains, besides the manganate and chloride of potassium, all the mineral impurities which

were present in the black oxide. It has a green color, and when treated with a little cold water yields a dark-green solution, which may be evaporated over sulphuric acid *in vacuo*, yielding blackish-green crystals. These dissolve unchanged in solution of potassa, but yield with water a solution which rapidly acquires a red color from the decomposition of the manganate into permanganate, manganic binoxide, and potassium hydrate: $3K_2MnO_4 + 2H_2O$ yields $K_2Mn_2O_8 + MnO_2 + 4KHO$. On account of this change of color the green manganate was formerly known as *chamdeon mineral*. The hydrate of potassium which is liberated in the reaction with water will dissolve a portion of the manganate without change until combined with carbonic, sulphuric, or other acid, when the whole of the manganate will be decomposed as stated. After the impurities and manganic peroxide have subsided the clear liquid is drawn off, the sediment drained and washed upon asbestos or powdered glass (since a paper or muslin filter would decompose the permanganate), and evaporated to crystallization. The first crop or two of crystals are usually pure; subsequently they become mixed with chloride and sulphate of potassium, and require to be purified by recrystallization. Finally, the other salts accumulate in the mother-liquors to such an extent that crystals of pure permanganate can no longer be obtained, and the liquids are advantageously used for disinfecting, bleaching, or other purposes.

Graeger (1866) proposed to utilize the manganic oxide, which may be obtained in large quantities and at little expense from the liquors, in the preparation of chlorine. The production of the manganate is explained by the equation $Mn_2O_3 + KClO + 4HKO_3 = 2K_2MnO_4 + KCl + 2H_2O$. The process of Städeler (1868) for converting the manganate into permanganate of potassium by means of chlorine gas, and without separation of manganic peroxide, is apt to contaminate the product with small quantities of potassium chlorate, but with due care yields the crystallized salt, equal to 85 or 90 per cent. of the weight of the black manganese used.

In a process proposed by Squibb (1864) the formation of other crystallizable salts is avoided by heating the intimate mixture of potassa and manganic peroxide thoroughly to short of redness; while the mass is hot a small stream of water is directed upon it; the heating is renewed and the operation several times repeated. The mass is exhausted with water, and after the permanganate has been crystallized the mother-liquor is evaporated and used over again in place of a corresponding quantity of potassa.

Properties.—Permanganate of potassium is in dark-purple or deep violet-red, nearly black rhombic prismatic crystals, which have a greenish or bluish metallic lustre, do not

FIG. 229.

Crystal of Potassium Permanganate.

react upon turmeric- or litmus-paper, are permanent in the air and without odor, and have a sweet, astringent taste. A small quantity of it imparts to a large quantity of water a rich purple tint, which is destroyed by organic matter and deoxidizing agents. Alcohol, acetone, acetic acid, oxalic acid, glycerin, tartaric acid, citric acid, sugar, gum, tannin, quinine, aniline, gelatin, and many other organic compounds are more or less readily oxidized in the cold or on boiling. According to Mitscherlich, the salt dissolves at 15° C. (50° F.) in 16 parts (20 parts, *U. S.*) of water and in 2 parts (3 parts, *U. S.*) of boiling water. The solution of the pure salt may be boiled without being decomposed, but in the presence of much potassa it acquires a green color from the formation of manganate, oxygen being given off at the same time: $K_2Mn_2O_8 + 2KHO$ yields $2K_2MnO_4 + H_2O + O$. A diluted solution of potassa exerts no reducing action except in the presence of organic matter. The solution of permanganate is decolorized by hydrosulphuric acid, carbon disulphide, hyposulphites, sulphites, phosphorus, hypophosphites, iodine, iodides, and many other inorganic oxidizable substances, as well as by organic compounds; the brown oxide which precipitates yields with diluted sulphuric acid a colorless or reddish solution. When heated to redness the salt parts with a portion of its oxygen and leaves a black residue of an alkaline reaction, from which water extracts potassium hydrate. When thrown upon red-hot charcoal it deflagrates, and on being triturated with sulphur or other

inflammable bodies the mixture is decomposed with detonation. On mixing its solution in a closed vessel with glycerin, syrup, or other liquids containing organic matter a similar decomposition, accompanied by explosion, will take place. A warm concentrated solution of it, mixed with nitrate of silver and allowed to cool, deposits large crystals of permanganate of silver, which require over 100 parts of water for solution and are decomposed on being boiled with water.

Tests.—The solution of the salt in much water should have a rose-color, without a tinge of green (absence of manganate). “If a solution of the salt be mixed with enough oxalic and diluted sulphuric acid to produce a clear, colorless liquid, and a portion of this be poured upon a cold solution of ferrous sulphate in sulphuric acid, no brown or blackish-brown zone should make its appearance at the line of contact of the two liquids (absence of nitrate). Another portion of the decolorized liquid should yield no permanent precipitate or cloudiness on the addition of a few drops of test-solution of nitrate of silver (chloride). On boiling the aqueous solution of the salt with an excess of ammonia until all the manganese is precipitated as hydrated oxide, the colorless filtrate (acidulated with nitric acid) should yield no precipitate, or at most only a faint cloudiness, with test solution of nitrate of barium (limit of sulphate).”—*U. S.* An excess of oxalic acid used for decolorizing the permanganate solution is likely to produce a precipitate with silver nitrate, the oxalate being almost insoluble in water. The presence of chloride and sulphate may be determined directly in a diluted solution of the permanganate, or the latter may be decolorized by boiling with alcohol (*P. G.*); such a solution, on being mixed with diluted sulphuric acid and zinc, and afterward with solution of starch and zinc iodide, should not acquire a blue color (absence of nitrate).—*P. G.* “If 0.785 Gm. of the salt be dissolved in 50 Cem. of boiling distilled water, and 5 Cem. of sulphuric acid be cautiously added, the solution so formed should require for complete decoloration not less than 24.7 Cem. of the volumetric solution of oxalic acid (corresponding to at least 98.8 per cent. of pure permanganate of potassium).”—*U. S.* The British Pharmacopœia requires 5 grains of the salt dissolved in water to be completely decolorized by a solution of not less than 44 grains of pure ferrous sulphate, acidulated with 2 fluidrachms of diluted sulphuric acid. This test depends upon the oxidation of 10 molecules (2779) of ferrous to ferric sulphate by 1 molecule (314) of pure permanganate of potassium.

Off. Prep.—Liquor potass. permanganatis, *Br.*

Physiological Action.—Vulpian found that a solution of permanganate of potassium (Gm. 1 : water Gm. 200 = gr. xv : f℥vi) thrown into the veins of a large dog occasioned general debility, prostration, vomiting, diarrhœa, and death in from 10 to 20 hours; rapid putrefaction, dissolved blood, ecchymoses in many parts, congestion of the gastro-intestinal mucous membrane and of the kidneys, bloody urine, sometimes pulmonary infarcts, etc. (*Bull. de thérap.*, cii., 251). The readiness with which permanganate of potassium yields its oxygen to bodies having a strong affinity for that element accounts for its alleged utility in limiting putrefaction and correcting putrid smells. For these purposes it was first used in 1857, but as regards the former of them the notion was erroneous, although exceedingly minute proportions of the salt neutralize the smell of putrefaction. A solution of 1 part in 5000 parts of water is promptly destructive of infusoria, but it does not destroy the germs upon which fermentation depends; a much stronger solution is necessary for that purpose. Applied pure to the sound skin, it produces a brown stain; upon mucous surfaces it causes neither pain nor irritation, but smarting and burning when applied to a raw surface. Internally, it has been taken in doses of from 8 to 10 grains without injury when largely diluted.

Medical Uses.—Internally, permanganate of potassium has been used in *diphtheria*, *diabetes*, and *acute rheumatism*, but without any beneficial results. Ringer and Murrell extol this salt as a most efficacious remedy for *amenorrhœa* due to transient causes, such as catching cold, and even where the suspension is due to repeated pregnancies and suckling. It was given in doses of a grain at first, but gradually increased to 2 grains four times a day, as near as possible to the regular date of menstruation, and continued for three or four days. Either in pill or in solution the medicine is apt to produce a sense of substernal pressure or heartburn, and in the latter form it is very disagreeable (*Practitioner*, xxx., 128). Locally, it is chiefly employed to correct fetor in *cancer*, especially of the uterus, in corroding *ulcers*, *ozœna*, *abscesses*, *caries*, and *gangrene*. In these cases it is applied in a strong solution with a brush or sponge, or in a weaker solution upon pledgets and compresses of lint. A similar application has been made to *carbuncles* after incision. In *ozœna* it forms one of the best palliatives when applied with the nasal douche, and has also been used with great advantage in an atomized solution inhaled in *gangrene of the lung*. Injections of the solution and lint saturated with it are among the best means of treating fetid *otorrhœa*. In the proportion of about 3 grains to an ounce (Gm. 0.20 in Gm. 32) of water it forms an excellent mouth-wash and gargle when *foul breath* arises from carious teeth or from the altered secretions of the faucial glands. As a wash it palliates the fetid exhalations of the *feet* and *armpits* in certain persons, and is useful in purifying the hands from the *smell* acquired in dissecting-rooms, in post-

mortem examinations, and in various obstetrical and surgical manipulations. In *gonorrhœa* a solution of 1 or 2 grains in an ounce (Gm. 0.06–0.12 in Gm. 32) of water is a very efficient injection. It seems to act partly as a stimulant of the urethral mucous membrane, and partly by its destructive action on the pus which is the vehicle of the specific virus in true gonorrhœa. In *leucorrhœa* stronger preparations may be employed, and the same may be applied to diminish the *leucial discharge* and correct its fœtor. Solutions of this salt have been widely used as disinfectants. But if the infectious qualities of decomposing animal matter are to be measured by its power of decolorizing a solution of permanganate of potassium, then a very curious conclusion has been reached by Dr. Dougall (1878)—viz. that 1 ounce of such matter, represented by the alvine discharges of typhoid fever, deoxidizes not less than 10 ounces of Condry's liquid, and that 1 ounce of urine has the same effect on at least 2 ounces of that liquid. It follows from these premises that each patient whose excreta are so treated would cost five dollars a day for this item alone. It is more than probable, therefore, that the method is hardly ever efficiently carried out. This salt has been recommended as an antidote to *serpents' poison* (Lacerda, *Bull. de thérap.*, ci. 325; civ. 556; Richards, *Times and Gazette*, Jan. 1882, p. 93). The observations and experiments that refer to the subject only prove that the permanganate mixed with any such poison destroys its virulence, and that if introduced into the wound made by a venomous animal immediately on the infliction of the wound, no toxic phenomena will arise. Evidently, this agent destroys the constitution of the poison. The introduction of the salt in any other way than that indicated, by the mouth, by intravenous injection, or hypodermically, except at the point at which the poison entered, is useless. It seems probable that such hypodermic injection of wounds made by rabid animals would be more efficient in preventing *rabies* than any other form of cauterization.

Water contaminated by organic matter may be purified and rendered palatable by adding to it drop by drop a solution of the permanganate until the pink color of the solution ceases to be destroyed after the lapse of 24 hours. The clear liquor may then be decanted and used without danger.

A solution of not more than 2 grains of the salt to a fluidounce (Gm. 0.12 in Gm. 32) of pure water is most appropriate as a commencing injection for the vagina and urethra and as a wash for simple wounds and ulcers. A solution of 8 grains to the fluidounce (Gm. 0.50 in Gm. 32) may be used for disinfecting purposes. Internally, it may be given in *doses* of from 2 to 5 grains (Gm. 0.13–0.30) dissolved in a large quantity of water. The stains left by this salt upon linen may be removed by washing it in water acidulated with sulphurous or muriatic acid, oxalic acid, salt of sorrel, or simply by lemon-juice, or finally by a weak solution of sulphate of iron.

POTASSII SULPHAS, U. S., Br.—SULPHATE OF POTASSIUM.

Potassæ sulphas, Br.; *Kalium sulfuricum*, P. G.; *Sulfas potassicus* s. *kalicus*; *Arcanum duplicatum*, *Tartarus vitriolatus*, *Sal polychrestum* Glaseri.—*Sulphate of potash*, E.; *Sulfate de potasse*, Fr.; *Kaliumsulfat*, *Schwefelsaures Kali*, G.

Formula K_2SO_4 . Molecular weight 174.

Origin.—This salt is present in sea-water and in various mineral waters, in the ashes of many plants, in many salt-beds, and in the lava of different volcanoes. It is obtained as a secondary product in many chemical processes, such as the preparation of iodine from kelp, of nitric acid from potassium nitrate, of hydrochloric acid from potassium chloride, and in the purification of potash, etc. It appears to have been prepared in the fourteenth century from the saline residue left in the preparation of nitric acid, and to have been used medicinally by Paracelsus in the sixteenth century. Glaser (1663) prepared it by adding sulphur to melted saltpetre.

Preparation.—In the manufacture of the products of the Stassfurt mines it is obtained by decomposing potassium chloride with a hot concentrated solution of *schornite* (sulphate of magnesium and potassium), and by separating the sulphate of potassium from the double chloride of potassium and magnesium, which is formed at the same time, before the latter can crystallize. In Kalusz, Galicia, the salt is prepared from *kainite*, a mixture of sulphate and chloride of magnesium and potassium, by exhausting with a little water, boiling the residue with potassium chloride, and granulating the newly-formed potassium sulphate.

Properties.—Sulphate of potassium crystallizes in transparent, colorless, and hard

six-sided rhombic prisms or pyramids, or combinations of the two forms. It is permanent in the air, inodorous, has a somewhat sharp and saline bitterish taste, is neutral to test-paper, has the specific gravity 2.65, and yields a white powder. According to Mulder (1864), the salt dissolves

at	5°	15°	30°	40°	60°	80°	100° C.
in	11	9.7	8.13	7.15	5.62	4.6	3.82 parts of water.

It has the specific gravity 2.65, is insoluble in alcohol, but dissolves in about 500 parts of diluted alcohol. The aqueous solution, acidulated with hydrochloric acid, gives with barium chloride a white, with platinic chloride a yellow, and with saturated solution of sodium bitartrate a white crystalline, precipitate. When heated it decrepitates strongly, melts at a bright-red heat without decomposition, and at a white heat volatilizes slowly in white non-alkaline vapors, leaving a residue which on cooling is crystalline and has an alkaline reaction; when mixed with an excess of chloride of ammonium and ignited it leaves potassium chloride. It imparts a purple color to the flame.

Tests.—The aqueous solution of sulphate of potassium should not be affected by sulphuretted hydrogen or sulphhydrate of ammonium (absence of heavy metals), nor should it be precipitated by carbonate or oxalate of ammonium (calcium, etc.), or by nitrate of silver (chloride). The solution, mixed with an equal volume of sulphuric acid, should not give a brown or black color on the addition of ferrous sulphate (nitrate). Held in a non-luminous flame, this should not be permanently colored yellow. 1 Gm. of sulphate of potassium, when completely precipitated by chloride of barium, yields 1.338 Gm. of dry sulphate of barium.

Off. Prep.—Pil. colocynth. comp., Pil. colocynth. et hyoseyami, Pulv. ipecacuanhæ comp., Br.

Allied Salt.—POTASSII BISULPHAS, KHSO_4 ; molecular weight 272. Bisulphate or acid sulphate of potassium is the saline mass remaining in the retort on preparing nitric acid from nitrate of potassium and sulphuric acid (see page 73), and may be obtained in needleshaped prisms by dissolving it in less than its own weight of boiling water and cooling. The crystals are colorless and transparent, have a strongly acid taste, an acid reaction to litmus, are fusible when heated, congealing on cooling to a translucent mass, and at a higher heat are decomposed, with the evolution of oxygen and sulphurous acid gas, neutral sulphate of potassium being left. The salt dissolves without change in 2 parts of cold water, but when dissolved in a larger quantity of hot water neutral sulphate crystallizes on cooling, the liquid containing sulphuric acid. A like decomposition into neutral sulphate and acid is occasioned by alcohol.

Medical Action and Uses.—Under the name of *Sal de duobus* or *Sal polychrest* sulphate of potassium was formerly used as a purgative. It acts in a smaller dose than other salines, but is apt to be harsh, producing colicky pain and burning in the abdomen. In several instances doses of from $\frac{1}{2}$ ounce to 2 ounces have caused fatal poisoning, and oftener alarming symptoms. The symptoms were severe gastric pain, vomiting, purging, and collapse. After death inflammation of the gastro-intestinal mucous membrane was found. Its *dose* as a purgative is from 2 to 4 drachms (Gm. 8–16), but it is seldom prescribed, nor does any good reason appear that it should be so employed. The bisulphate is represented as possessing the qualities of the sulphate in a more marked degree.

POTASSII SULPHIS, U. S.—SULPHITE OF POTASSIUM.

Kalium sulfurosam, Sulfis potassicus s. kaliæ.—*Sulfite de potasse*, Fr.; *Kaliumsulfit, Schwefligsaures Kali*, G.

Formula $\text{K}_2\text{SO}_3 \cdot 2\text{H}_2\text{O}$. Molecular weight 194.

Preparation.—On passing sulphurous acid gas into a solution of carbonate of potassium until the carbonic acid has been expelled, and adding an equal weight of potassium carbonate, the sulphite, having the above composition, will crystallize on evaporation.

Properties.—Sulphite of potassium crystallizes in oblique rhombic octahedrons, which are inodorous or of a slight sulphurous odor, somewhat deliquescent, dissolve freely in water, are sparingly soluble in alcohol, show an alkaline reaction to test-paper, and have a bitter saline and sulphurous taste. Rammelsberg ascertained that an aqueous solution of the salt saturated in the cold becomes turbid on heating and clear again on cooling. Fourcroy and Vauquelin determined the salt to be soluble in its own weight of cold water; the U. S. P. states the solubility as being 1 part in 4 parts of water at

FIG. 230.

Crystal of Potassium Sulphate.

15° C. (59° F.) and in 5 parts of boiling water. When heated the salt gives off water, evolves sulphurous acid, and leaves finally a mixture of sulphate, sulphide, and hydrate of potassium. On exposure to the air it is oxidized and gradually converted into sulphate; it should therefore be preserved in well-stopped bottles. On adding sulphuric or hydrochloric acid to its solution the odor of burning sulphur is given off, but no turbidity from liberated sulphur is produced (difference from hyposulphite). This solution gives the reactions of potassium salts on the addition of chloride of platinum or of tartaric acid or of saturated solution of sodium bitartrate. The commercial salt is usually in the form of white opaque crystalline fragments or powder, obtained by evaporating the aqueous solution.

Composition.—The salt contains 48.5 per cent. K_2O , 33 per cent. SO_2 , and 18.5 per cent. H_2O .

Tests.—A 1 per cent. aqueous solution of the salt, strongly acidulated with hydrochloric acid, should produce no precipitate, or at most only a white cloudiness, on the addition of a few drops of test solution of chloride of barium (limit of sulphate). If 0.485 Gm. of the salt be dissolved in 25 Ccm. of water, and a little gelatinized starch added, at least 45 Ccm. of the volumetric solution of iodine should be required until a permanent blue tint appears after stirring (corresponding to at least 90 per cent. of pure sulphite of potassium).—*U. S.* The same amount of the volumetric solution of iodine is required by 0.27 Gm. of pure bisulphite of potassium.

Allied Salts.—BISULPHITE OF POTASSIUM, $KHSO_3$; molecular weight 120. It is prepared by passing into a concentrated solution of carbonate of potassium an excess of sulphurous acid gas and adding strong alcohol. The salt crystallizes in white needles, has a sulphurous taste and neutral reaction to test-paper, and on exposure slowly evolves sulphurous acid gas. On passing sulphurous acid gas into a warm saturated solution of potassium carbonate the liquid finally becomes greenish, and on cooling deposits hard, glossy, tabular crystals of *potassium pyrosulphite*, $K_2(SO_3)_2O$, which have a saline taste, and on heating give off sulphur and sulphur dioxide, leaving potassium sulphate.

Medical Action and Uses.—The sulphite of potassium is believed to possess the same power of controlling fermentation and putrefaction which belongs to the sulphites of sodium and magnesium. But it is much less used than either. It may be given internally, in a very dilute solution, to the extent of from 2 drachms to $\frac{1}{2}$ ounce (Gm. 8–16) in the 24 hours. The hyposulphite and the bisulphite have analogous properties, and the latter has sometimes been used externally as a stimulant and deodorizer.

POTASSII TARTRAS, *U. S., Br.*—TARTRATE OF POTASSIUM.

Potassæ tartras, Br.; *Kalium tartaricum*, P. G.; *Tartras potassicus s. kalicus*, *Tartarus solubilis*.—*Tartrate of potash*, *Soluble tartar*, E.; *Tartrate de potasse*, *Tartre soluble*, *Sal végétale*, Fr.; *Kaliumtartrat*, *Neutrales weinsaures Kali*, G.

Formula $(K_2C_4H_4O_6)_2 \cdot H_2O$. Molecular weight 470.

Preparation.—This salt appears to have been known in the sixteenth century. Boerhaave (1732) prepared it by neutralizing cream of tartar with salt of tartar, and named it *tartarus tartarizatus*. That a solution of the same salt is obtained on neutralizing cream of tartar with lime was shown by Rouelle and Marggraf (1770). It is obtained in the first part of the process for making tartaric acid (see page 107), but it is usually prepared by Boerhaave's process, or preferably with potassium bicarbonate, using 25 parts of this salt, 47 parts of pure potassium bitartrate, and about 100 parts of boiling water. The neutral or faintly alkaline solution is concentrated until a pellicle forms, and set aside to crystallize; the crystals are drained and dried. The mother-liquor is further concentrated, and when it begins to yield colored crystals may be decomposed by hydrochloric acid to obtain the remaining salt as bitartrate. The yield of crystallized potassium tartrate is about 55 or 56 parts.

The British Pharmacopœia directs 9 ounces of carbonate of potassium, 20 ounces of acid tartrate of potassium, and 50 ounces of water, and proceeds in all essential details as stated above. In the reaction between the two salts 1 molecule (188) of cream of tartar decomposes $\frac{1}{2}$ molecule (69) of dry carbonate or 1 molecule (100) of bicarbonate of potassium, forming the neutral tartrate: $2KHC_4H_4O_6 + K_2CO_3$ yields $2K_2C_4H_4O_6 + CO_2 + H_2O$, and $KHC_4H_4O_6 + KHCO_3$ yields $K_2C_4H_4O_6 + CO_2 + H_2O$. Provided the salts are pure, it will be observed that 16 parts of anhydrous carbonate will require $43\frac{2}{3}$ parts of bitartrate, and 9 parts of the former $24\frac{1}{2}$ parts of the latter, for complete neutralization. In the last formula there is a considerable excess of carbonate, which requires to

be neutralized by the further addition of bitartrate. If the latter has been contaminated with tartrate of calcium, this salt may be decomposed by prolonged boiling with potassium carbonate, calcium carbonate being deposited. Calcium tartrate is soluble in a solution of potassium tartrate, and, unless decomposed as stated, is best removed by evaporating the solution to dryness, granulating the salt, and treating it with twice its weight of cold water, when most of the calcium tartrate will be left undissolved. The same treatment, and for the same reason, is also advisable if potassium tartrate is obtained as a by-product in the manufacture of tartaric acid, by neutralizing cream of tartar, diffused in boiling water, with calcium carbonate, when potassium tartrate contaminated with calcium tartrate will remain in solution.

Properties.—Tartrate of potassium crystallizes in four- or six-sided colorless and transparent crystals of the monoclinic system, which in the presence of calcium tartrate are white and rather opaque. It is more frequently met with as a granular or fine white powder, is inodorous, has a saline bitterish taste, is without action on litmus-paper, and may be heated to 100° C. (212° F.) without losing in weight: but at 180° C. (356° F.) 1 molecule (3.8 per cent.) of water is given off (Dumas and Piria), and near 220° C. (428° F.) about 5.5 per cent. of acetone and other volatile products, the residue containing potassium carbonate; above this temperature the salt becomes colored, melts, gives off inflammable vapors with the odor of burnt sugar, and leaves a black residue having an alkaline reaction and effervescing strongly with acids. Heated with sulphuric acid, it forms a black tarry fluid, evolving inflammable gas and the odor of burning sugar. It requires 240 parts of boiling alcohol for solution, and is nearly insoluble in cold alcohol. The salt absorbs moisture on exposure to the air, and is gradually liquefied when kept in a damp atmosphere. According to Osann, it dissolves at 2° C. (35.6° F.) in .75 part, at 14° C. (57.2° F.) in .66 part, and at 64° C. (147.2° F.) in .47 part, of water. The aqueous solution yields with calcium chloride a white precipitate soluble in acetic acid and in cold potassa solution, and it gives a white precipitate with silver nitrate, becoming black on boiling. Acetic acid added to its aqueous solution causes the separation of a white crystalline precipitate consisting of bitartrate of potassium.

Tests.—When 122 grains are heated to redness till gases cease to be evolved, the alkaline residue will require for exact neutralization 990 grain-measures of the volumetric solution of oxalic acid. (*Br.*) or 25 Cem. of the latter for 2.938 of the salt (*U. S.*). If sodium is present a larger quantity of the acid solution will be required. Sodium would also be indicated by the yellow color imparted to a non-luminous flame by the alkaline residue left on ignition. Carbonate is detected by the effervescence on the addition of an acid, and ammonia by its odor on warming the solution with potassa or soda. "A 5 per cent. aqueous solution of the salt should not be affected by sulphide of ammonium (iron, zinc, lead, aluminium), nor by oxalate of ammonium (calcium), nor after acidulation with hydrochloric acid by hydrosulphuric acid (lead, copper, etc.), or by barium nitrate (sulphate). A similar solution of the salt acidulated with nitric acid should at most become opalescent on the addition of silver nitrate (chloride)." — *P. G.* The U. S. P. directs testing for calcium salt in a 10 per cent. solution, and for sulphate and chloride in a 1 per cent. solution, of the salt.

Composition.—The French Codex recognizes the anhydrous salt $K_2C_4H_4O_6$, mol. weight 226. The U. S. P. adopts the view of Dumas and Piria of the presence of $\frac{1}{2}H_2O = 3.83$ per cent. The *Br. P.* gives the formula $K_2C_4H_4O_6 \cdot H_2O$, mol. weight 244, and by its alkalimetric test admits 1 per cent. of impurity.

Other Soluble Tartars.—The name of *soluble tartar* was formerly applied also to other tartars, of which two are still recognized by European pharmacopeias:

TARTARUS BORAXATUS, P. G.: *Cremer tartari solubilis, Kalium tartaricum boraxatum, Borax tartarisatus.*—Boro-tartrate of potassium and sodium, *E.*: *Tartro-borate de potasse et de soude, Fr.*: *Boraxweinstein, G.*—2 parts of borax are dissolved in 20 parts of distilled water and digested with 5 parts of cream of tartar. When entirely dissolved the filtered liquid is evaporated with constant stirring, the resulting residue dried in thin layers, and while still warm reduced to powder and preserved in well-corked bottles.—*P. G.* It is a white, amorphous, deliquescent powder of an agreeably acidulous taste and acid reaction. It is soluble in its own weight of cold and less than half its weight of boiling water, insoluble in alcohol, and when heated is decomposed, leaving a residue of borax, carbonate of potassium, and charcoal. The aqueous solution of the salt is not disturbed by acetic acid or by a small quantity of diluted sulphuric acid, but after the addition of tartaric acid a crystalline precipitate is produced. Moistened with sulphuric acid, the salt imparts a green color to the flame of alcohol. A 10 per cent. aqueous solution should not be altered by sulphide of ammonium (metals), should not evolve ammonia on being warmed with potassa, should not be precipitated by ammonium oxalate

(calcium), and after the addition of a few drops of nitric acid it should not be precipitated by barium nitrate, and should merely become opalescent with silver nitrate.

POTASSII TARTRIO-BORAS, Tartarus borico-potassicus.—Boro-tartrate of potassium, *E.*: Tartrate borico-potassique, *Crème de tartrate soluble*, *Tartre boraté*, *Fr.*: Borsäureweinstein, *G.*—4 parts of cream of tartar, 1 of boric acid, and 10 of water are heated together until dissolved; the solution is evaporated to dryness and the residue powdered.—*F. Cod.* It forms a white inodorous powder or may be obtained in thin transparent scales, has an acidulous taste, is not deliquescent, and dissolves in 2 parts of cold water. When long kept it becomes less soluble in water, but its solubility is restored on treating it with boiling water.

AMMONII ET POTASSII TARTRAS, Tartarus solubilis ammoniatus.—Tartrate of ammonium and potassium, *E.*: Tartras de potasse et d'ammoniaque, *Fr.*: Weinsaures Ammoniak-Kali, *G.* $\text{KNH}_4\text{C}_4\text{H}_4\text{O}_6$; molecular weight 205.—It is prepared by diffusing 1 part of cream of tartar in $2\frac{1}{2}$ or 3 parts of boiling water, adding carbonate of ammonium as long as effervescence takes place, filtering, and crystallizing. It is well to render the solution alkaline by the addition of a little ammonia. The double salt crystallizes in transparent prisms having a pungent and cooling saline taste and becoming opaque on exposure from loss of ammonia. It is soluble in about 2 parts of cold and less than its own weight of hot water.

Medical Action and Uses.—Tartrate of potassium appears to promote the urinary secretion when given in small doses freely diluted, but in larger quantities it operates as a laxative. It is excreted by the kidneys as carbonate of potassium, in full doses rendering the urine alkaline. It may be used as a mild cooling purgative in all affections requiring saline aperients. It acts more gently than the sulphate of sodium or magnesium. Like other salines, it renders the bile more liquid and promotes its secretion, and hence it may be used in cases of *hepatic and portal congestion*, and especially for the relief of *hemorrhoidal swellings*. It is not unusual to associate it with senna, manna, or rhubarb, which concur in producing those effects, and with scammony and gamboge to mitigate the griping operation of those medicines. It is not very often used at present. As a purgative its dose is from half an ounce to an ounce (Gm. 16–32).

Boro-tartrate of potassium and sodium is a mild laxative or diuretic when given dissolved in a large proportion of water, the former in doses of from half an ounce to an ounce (Gm. 16–32), and the latter in doses of from 10 to 30 grains (Gm. 0.60–2). Husemann mentions larger doses (Gm. 25–60) for purgation, and adds that the preparation is costly, and that a convenient and cheaper substitute for it may be prepared by mixing 2 parts of cream of tartar with 1 part of borax. The *tartrate of ammonium and potassium* has also been used as a diuretic and laxative in the doses first above mentioned.

POTENTILLA.—CINQUEFOIL.

Fivefinger, *E.*; *Potentille*, *Fr.*; *Fingerkraut*, *G.*

Potentilla canadensis, *Linné*.

Nat. Ord.—Rosaceæ, Dryadeæ.

Description.—This perennial herb is common in dry fields and woods of North America. It has an ascending or procumbent stem, which sometimes remains simple (*Pot. simplex*, *Michaux*), but usually produces slender and creeping runners; the radical leaves are long-petiolate, the stem-leaves on short petioles or nearly sessile; all are digitately five-foliate, with the leaflets about 1 inch (25 Mm.) long, wedge-obovate and incised or toothed above. The peduncles are axillary, about as long as the leaves, and one-flowered; the calyx is five-cleft, with five bract-like appendages between the lobes; the five petals are yellow; the stamens and ovaries are numerous, the latter on ripening forming akenes attached to a convex dry receptacle. The entire plant is more or less silky-hairy, inodorous, and has a somewhat astringent and bitterish taste. It flowers from April to September.

Allied Plants.—POTENTILLA ANSERINA, *Linné*.—Silverweed, *E.*: Argentine, *Ansérine*, *Fr.*: Gänserich, Silberkraut, *G.*—This is indigenous to the northern hemisphere: it has radical, interruptedly pinnate leaves, composed of nine to nineteen oblong, deeply serrate leaflets, which are silvery white and downy underneath. It has solitary, long-peduncled flowers, and produces thread-like runners which take root at the nodes.

POT. FRUTICOSA, *Linné*. *Shrubby cinquefoil*, is likewise found in the northern hemisphere: is shrubby, about 3 feet (9 M.) high, has pinnate leaves, with five to seven linear or lance-oblong, entire, and silky leaflets, and numerous flowers.

POT. RUPESTRIS, *Linné*, a native of the mountainous parts of Europe and Siberia, has pinnate radical and three-lobed stem-leaves.

POT. PALUSTRIS, *Scopoli*, s. *Comarum palustre*, *Linné*, *Marsh cinquefoil*, grows in cool, boggy localities in Europe and North America: has the leaves with five or seven lance-oblong underneath whitish leaflets and purple-colored flowers.

POT. ARGENTEA, *Linné*. *Silvery cinquefoil*, grows in dry fields in North America and Europe: has an ascending stem, palmately five-foliate leaves and wedge-oblong, incised and beneath silvery canescent leaflets.

POT. REPTANS, *Linné*.—Creeping cinquefoil, *E.*: Potentille rampante, Quintefeuille, *Fr.*: Fünf-fingerkraut, *G.*—It grows in moist fields in Europe and Asia; has slender, creeping stems, long-petiolate, palmately five-foliate leaves, oblong-obovate, deeply serrate leaflets, and single, axillary, long-stalked flowers.

With the exception noted, all the above species have yellow flowers; they are inodorous, and their roots and herbaceous portions have a slightly astringent and bitterish taste.

Constituents.—The plants contain a little tannin, bitter, mucilaginous, and other common vegetable principles.

Medical Action and Uses.—Creeping cinquefoil is almost identical in its qualities with *P. tormentilla*. It has been employed from ancient times in Europe, on account of its slight astringency, as a remedy for *diarrhœa*, *dysentery*, *leucorrhœa*, *passive hæmorrhages*, *sore throat*, etc., and is still used as a domestic remedy. The other species have similar properties. It is generally given in a decoction made with from 2 to 4 drachms to 8 ounces of water (Gm. 8–16 in Gm. 250), and in tablespoonful doses.

PRENANTHES.—RATTLESNAKE-ROOT.

Lion's-foot, *White lettuce*, *Cancer-weed*, *Gall of the earth*.

Prenanthes (*Harpalyce*, *Don*) *alba*, *Linné*, s. *Nabalus albus*, *Hooker*.

Nat. Ord.—Compositæ, Ligulifloræ.

Description.—This North American perennial grows in rich soil on the borders of woods, and flowers in July and August. The stem is 3 to 6 feet (.9–1.8 M.) high, purplish and glaucous, branched above, and grows from a tuberous, spindle-shaped root. The leaves are petiolate, angular, hastate, the radical ones palmately five- or seven-lobed, those of the stem ovate-roundish and sinuate-toothed; the flower-heads are in loose, racemose cymes, drooping, have a cylindrical involucre, with the linear, purplish, and white scales in a single row, and a few bractlets at the base, and contain from eight to twelve ochroleucous or purplish florets, with linear-oblong, striate, and unbeaked akenes, and a pale-brownish pappus composed of several rows of rough hairs. All parts of the plant contain a milky juice and have a bitter taste. The variety *serpentaria* has the lower leaves almost palmately divided and the stem-leaves three-lobed or deeply toothed.

No analysis of its constituents has been made.

Medical Action and Uses.—The extreme bitterness of the root of this plant caused it to be used as a domestic tonic in the Southern States. Nearly thirty years ago it was affirmed to be a certain remedy for the *rattlesnake's bite*, in confirmation of a long antecedent tradition. "The milky juice of the plant was taken internally, and the leaves, steeped in water, were applied to the wound and frequently changed." No recent addition appears to have been made to these statements.

PRIMULA.—PRIMROSE.

Cowslip, *E.*; *Primevère*, *Fr.*; *Schlüssellblume* *Primel*, *G.*

Primula officinalis, *Jacquin*, s. *P. veris*, *Linné*.

Nat. Ord.—Primulacæ.

Origin.—The primrose is an acaulescent perennial indigenous to woodlands and grassy places of Europe and Northern Asia and frequently cultivated in gardens.

Description.—The subterraneous portion consists of a short, upright, brownish, and scaly root-stalk, beset with a number of fleshy rootlets, about 6 inches (15 Cm.) long, and containing a thick mealy bark and a yellowish medullium. The flowers (*flores primulæ*) are upon short or elongated scapes in umbels of ten or twelve pendulous flowers; the calyx is $\frac{1}{2}$ inch (12 Mm.) or more long, pentangular, tubular, somewhat inflated, acutely lobed, and pale-yellowish; the corolla is about an inch (25 Mm.) long, funnel-shaped, five-lobed, the lobes obovate, of a lemon-yellow color, and has in the throat five saffron-colored spots. The corolla alone is collected. It has when fresh a honey-like odor and a sweetish taste, and on drying usually acquires a dark-greenish color. The fresh root has a slight sweetish odor and a sweetish afterward bitterish and acid taste.

Constituents.—The odor of the root and flowers appears to be due to a small quantity of a butyrateous volatile oil. The *primulin* of Hünefeld is considered by Gmelin to

be identical with mannit. The acrid principle is either saponin or closely related to it; Saladin (1830) regarded it as identical with cyclamin.

Allied Plants.—*PRIMULA ELATOR*, *Jacquin*. The flowers are large and inodorous; the corolla is sulphur-yellow, and has a flat margin, with emarginate, not cordate, lobes.

PRIMULA AURICULA, *Linné*. The auricula is a native of mountainous regions of Europe, and, like both preceding species, often cultivated; the corolla is fragrant, in the wild state lemon-yellow, and has a flat margin; the short calyx has rather obtuse lobes.

ANAGALLIS ARVENSIS, *Linné*.—Red chickenweed, Red pimpernel, Weather-glass, *E.*: Mouron rouge, *Fr.*: Gauchheil, Rothe Miere, *G.*—A European weed naturalized in sandy fields of North America. It has a procumbent or ascending branched quadrangular stem about 10 inches (25 Cm.) long, and opposite or whorled sessile ovate and three-nerved leaves, entire on the margin and blackish-punctate beneath; the small flowers are axillary, long-peduncled, and have a brick-red corolla little exceeding the calyx. An. cerulea, *Schreber*, the blue pimpernel, has a blue corolla. The plants are inodorous and have a somewhat bitter and acrid taste, which is due to saponin (*D. Malapert*, 1857) or to cyclamin (*Saladin*, 1830).

LYSIMACHIA NUMMULARIA, *Linné*.—Moneywort, *E.*: Monnayère, *Fr.*: Pfennigkraut, *G.*—A creeping European plant, frequently cultivated and somewhat naturalized in North America. The leaves are short-petioled, roundish, smooth, and finely brown punctate; the flowers are axillary, bright-yellow, and rather large.

LYSIMACHIA QUADRIFOLIA, *Linné*, Crosswort. It is a common North American herb, with an erect hairy stem, with petioled lance-ovate leaves in whorls of four and five, and with long-peduncled, axillary yellow flowers.

Medical Action and Uses.—The bitter, astringent, and acrid taste of the root, and also the aroma of the flowers of this plant, doubtless first led to its being employed medicinally, and the discovery in it of a substance compared to saponin by some, and to mannit or senegin by others, confirms the popular belief that it possesses medicinal virtues. *Pliny* speaks of its popular esteem as a panacea, "In aqua potam omnibus morbis mederi tradunt." It is represented as being a stimulant of the bronchia and of the stomach, its powdered root is an active sternutatory, and the whole plant was formerly held to be anodyne, narcotic, and anti-spasmodic, and was used by noted physicians of the last two centuries for the relief of *toothache*, *insomnia*, spasmodic *hysterical* attacks, *hemiplegia*, *dysmenorrhœa*, and muscular *rheumatism*. So fixed was the belief in its power of curing *gout* and *paralysis* that among the names it bore were *radix arthritica*, *radix paralysisos*. An infusion of the flowers was thought to be especially adapted to functional nervous disorders. A decoction of the root was given for the cure of *gravel*, and an infusion in wine or beer as a *vermifuge*. In England a fermented drink known as "cowslip wine" has long been one of the most esteemed articles of the domestic pharmacopœia, and in some parts of Germany an allied species, *P. auricula*, has for centuries been used as a remedy for consumption. It will be well if some of the heroic medicines of the present day shall, after as great a lapse of time, have as favorable a record of their virtues as this humble plant enjoys. The dose of the flowers is stated to be 15 or 20 grains (Gm. 1-1.30), and an infusion is made with from 5 to 10 parts to 100 of water.

PRINOS, U. S.—BLACK ALDER.

Winterberry, *Feverbush*, *E.*; *Prinos*, *Fr.*, *G.*

The bark of *Prinos verticillatus*, *Linné*, s. *Ilex verticillata*, *Gray*.

Nat. Ord.—Aquifoliaceæ.

Origin.—The black alder or winterberry is a shrub about 8 feet (2.4 M.) high, growing in low swampy ground in Canada and the United States. It has alternate oval or obovate, acuminate, serrate leaves, about 2 or 3 inches (5 to 8 Cm.) long, downy on the veins beneath, and narrowed into petioles about $\frac{1}{2}$ inch (12 Mm.) long. The small whitish flowers are dioeciously polygamous, have a subrotate, six-parted corolla, usually six stamens, and are in little umbels, all on very short peduncles. The fruit is a globose, bright-red, six-seeded berry, which is persistent in winter, grows in clusters, apparently verticillate, and has an acidulous and bitter taste. The plant flowers in May and June, and ripens the fruit in October.

Description.—The bark is in slender pieces, $\frac{1}{4}$ or $\frac{1}{2}$ inch (6-12 Mm.) wide, or in fragments, about $\frac{1}{25}$ inch (1 Mm.) thick, fragile; externally of a brownish ash-color, with irregular light-gray or whitish patches lined with black and sprinkled with minute black or small brown circular spots. Older bark is marked with short, transverse, oblong, shallow scars, often margined with ridges. The inner surface is pale-greenish or orange-yellow, shortly striate, otherwise smooth, and has frequently thin sections of the white wood

adhering. The bark breaks with a short fracture, and shows upon transverse section a green color and a tangential arrangement of tissue. It is inodorous, and has a bitter somewhat astringent taste.

Constituents.—L. C. Collier (1880) found in the bark chlorophyll, wax, resin, tannin, sugar, starch, albumen, and an amorphous yellow bitter principle which is precipitated by basic lead acetate and by salts of platinum, silver, mercury, and tin.

Allied Species.—*PRINUS* (LEX, *Gray*) *LEVIGATUS*, *Pursh*, grows in wet grounds in the Northern States, and southward in the mountains to Virginia, and is distinguished by its lanceolate or lance-oblong and smooth leaves, and by the staminate flowers being on slender peduncles.

PRINUS GLABER, *Linné*, s. *Ilex glabra*, *Gray*, known as *inkberry*, is found near the coast from Massachusetts southward, but chiefly in the Southern States. It has coriaceous, smooth, lanceolate, or oblong leaves, with a wedge-shaped base, and serrate near the apex; the berries are black.

Medical Action and Uses.—The bark of black alder is astringent and tonic, and is popularly employed in *intermittent fever* and *diarrhœa*, as a topical application to *gangrenous* and other ill-conditioned sores, and both internally and locally in chronic *cutaneous eruptions*. It is prescribed in substance in doses of 30 grains (Gm. 2), and in a decoction made with 2 ounces (Gm. 64) of the bark in 3 pints of water boiled to a quart, of which the dose is 2 or 2 fluidounces (Gm. 64–96). A saturated tincture is also prepared with the berries as well as with the bark.

PRUNUM, U. S., Br.—PRUNES.

Prunes, Fr.; *Pflaumen*, *Zwetschen*, G.

The fruit of *Prunus domestica*, *Linné*. Bentley and Trimen, *Med. Plants*, 96.

Nat. Ord.—Rosaceæ, Amygdalææ.

Origin.—The plum tree is indigenous to Western Asia. It has been cultivated from a very early period, and is now met with in most countries having a temperate climate. A large number of varieties have been produced, differing in the size, color, and shape of the fruit. The tree is about 20 feet (6 M.) high, without thorns, has oval-elliptic serrate leaves and whitish pedunculate flowers, either solitary or in pairs. Some botanists consider the subglobular plums to be the cultivated varieties of *Prunus insititia*, *Linné*, which resembles the other species, but is thorny and has elliptic or somewhat lanceolate leaves. The Br. P. orders the ovoid or oblong fruit of the var. *Juliania*, *DeC.*

Description.—The dried fruit is a subglobular or oblong drupe of a dark-blue or purplish-blue color, glaucous, shrivelled, with a shallow longitudinal furrow, the sarcocarp brownish-yellow, and the putamen hard, oblong, somewhat oblique, more or less flattened, smooth, or with irregular ridges. The seeds resemble the almond, but are smaller. The fleshy portion of the fruit, which is alone used, has an agreeable, sweet, and acidulous taste; the seed has the taste of bitter almond, and contains about 25 per cent. of a yellow bland fixed oil.

Constituents.—Prunes contain sugar, pectin, albumen, malic acid, and various salts. The sugar of the different varieties varies in amount between about 12 and 25 per cent. of the weight of the fresh fruit.

Off. Prep.—*Confectio sennæ*, U. S., Br.

Medical Action and Uses.—Prunes are nutritious and laxative, but in excess are apt to create flatulence and colic, owing chiefly to the indigestibility of their skins. When stewed with sugar they relieve *costiveness*, and are more efficient when thus prepared with senna, whose tendency to gripe they partially correct. For this reason they enter into the confection of senna.

PRUNUS VIRGINIANA, U. S.—WILD-CHERRY BARK.

Ecorce de cérisier de Virginie, Fr.; *Wildkirschenrinde*, G.

The bark of *Prunus* (*Cerasus*, *Loiseleur*) *serotina*, *Ehrhart*, s. *Prunus* (*Cerasus*, *Michaux*) *virginiana*, *Miller*. Bentley and Trimen, *Med. Plants*, 97.

Nat. Ord.—Rosaceæ, Amygdalææ.

Origin.—The wild cherry is a large North American forest tree, growing from Canada to Florida and westward to Eastern Nebraska and Texas. It attains the height of 60 or 80 feet (18 to 24 M.) with the trunk sometimes 4 feet (1.2 M.) in diameter and undivided to the height of 20 or 30 feet (6 or 9 M.). When grown in the open field it is usually much smaller. The wood is compact, close-grained, and pale-red or brownish-red. The

leaves are alternate lance-oblong, taper-pointed, petiolate, 3 to 5 inches (7 to 12 Cm.) long, and are finely serrate, with incurved teeth. The small white flowers are in elongated racemes 4 or 5 inches (10–12 Cm.) long, and terminal on the branchlets. The fruit is a small, globose, purplish-black drupe of a sweet and bitterish taste. The subglobular seed has the flavor of bitter almonds, and contains about 25 per cent of a bland green-yellow fixed oil, which readily separates a granular deposit. The leaves were suggested by Prof. Procter (1858) as a substitute for cherry-laurel leaves, and found to yield nearly $\frac{1}{10}$ per cent. of hydrocyanic acid when recently collected. This species has long been confounded with the *choke cherry*, *Prunus* (*Cerasus*, *De Candolle*) *virginiana*, Marshall, s. *Prunus obovata*, Bigelow. This is likewise a native of Canada and the United States, but grows westward to Colorado and Central Texas. It is shrubby, about 8 or 10 feet (2.4 or 3 M.) high, or arborescent, has thinner oval or obovate and abruptly pointed, sharply serrate leaves, short and close racemes, and red or purplish fruits of an astringent and bitterish taste.

Description.—Wild-cherry bark is met with in irregular fragments or slightly curved pieces; the thinner pieces are obtained from the branches and trunks of younger trees, are about $\frac{1}{12}$ inch (2 Mm.) thick, externally of a blackish-gray or green-brownish color, smooth and somewhat shining, or partly deprived of the exfoliating corky layer, and then of a greenish or light yellowish-brown. Older bark has usually the outer corky layer removed, is $\frac{1}{8}$ inch (3 Mm.) and more in thickness, and has a rather uneven outer surface of a rust-brown color. The inner surface is smooth, somewhat striate, cinnamon-colored or rust-brown. The bark is brittle, breaks with a granular fracture, is radially striate upon transverse section, and yields a pale reddish-brown powder. It has a very slight odor while dry, but when macerated in water it develops the odor of bitter almond; its taste is astringent, aromatic, and bitter, with the flavor of bitter almond. The thick corky layer of old bark, if present, should be rejected. The bark should be collected in October.

Constituents.—Stephen Procter (1834) showed the bark to contain tannin, gallic acid, resin, starch, and other common vegetable principles, and obtained by distillation a volatile oil containing hydrocyanic acid. This volatile oil was further examined by Prof. Procter (1837, 1838), and found to agree in the main with the volatile oil of bitter almond, and, like this, to be produced from *amygdalin* by the action of a proteid resembling emulsin, or perhaps identical with it. It is coagulated or altered by heat, and the powdered bark, introduced into hot water, does not yield any volatile oil. J. S. Perot (1852) ascertained that the bark collected in autumn yielded three times as much hydrocyanic acid as that collected in April. From the latter he obtained .0478 per cent.; when gathered in October the yield was .1436 per cent., or $\frac{1}{4}$ grain HCN from 100 grains of the bark, which would therefore be equal to about 7 or 8 drops of official hydrocyanic acid. The same author ascertained also that the bitter principle of wild-cherry bark is not phlorizin. J. L. Williams (1875) obtained the bitter principle by concentrating the aqueous infusion, mixing it with an equal bulk of alcohol, agitating with milk of lime, evaporating the filtrate, and exhausting the residue with hot alcohol, on the spontaneous evaporation of which a transparent, brownish, somewhat gelatinous, bitter mass was left; it was insoluble in ether, somewhat soluble in water, more soluble in alcohol, and was colored brown-red by sulphuric acid. The bark from the trunk, as well as from the root, was found by J. L. Lemberger (1871) to contain the largest proportion of tannin when collected in October, and to yield then also infusions of a dark wine-color. C. F. Kramer (1882) estimated the tannin with gelatin and found 3.42 per cent.

Off. Prep.—Extract. pruni virg. fluid., Infus. pruni virg., Syrup. pruni virg., U. S.

Medical Action and Uses.—Wild-cherry bark is tonic through its bitter principle, and more or less sedative through the hydrocyanic acid which it generates with water. For the latter effect, however, very large doses are required. It is more used in pulmonary consumption than in any other disease, under the impression that it improves the appetite and strengthens the digestion, while it moderates the cough and allays the irritability of the nervous system. It is a gentle and harmless palliative in this disease, while its use may prevent the employment of opiate and expectorant mixtures, whose injurious influence on the digestion outweighs their utility in moderating the cough. It is particularly useful in cases of nervous cough produced by reflex action, or even by slight bronchial or laryngeal irritation. It is equally useful during convalescence from various acute diseases when febrile excitement is maintained by general debility of the system. *Palpitation of the heart* is reputed to be especially under its control. When this symptom depends upon organic causes the medicine is inadequate to allay it except in a very slight degree; but when it is associated, as it more frequently is, with anemic,

chlorotic, dyspeptic, or nervous disorders, the bark is sometimes of real advantage. The cold infusion forms a useful collyrium in mild cases of acute *ophthalmia*.

The dose of the powdered bark is stated to be from 30 to 60 grains (Gm. 2-4). The cold infusion and the fluid extract are more efficient and eligible preparations; the syrup is chiefly to be recommended as a flavoring agent.

PSORALEA.—PSORALEA.

Psorale, Fr.; *Psoralie*, *Drüsenklee*, G.

Nat. Ord.—Leguminosæ, Papilionacæ.

Description.—The genus is characterized by a five-cleft persistent calyx having the lowest lobe longest, by diadelphous or sometimes monadelphous stamens, by a short one-seeded pod, the pointed end of which projects from the calyx, and by the glandular dots with which the calyx, and frequently also the leaves, are more or less covered. The following species have been employed:

PSORALEA MELILOTOIDES, *Michaux*, s. *P. eglandulosa*, *Elliott*, grows in dry soil in the Southern and Western United States, is a slender, erect, pubescent, and slightly glandular herb about 2 feet (60 Cm.) high, and has a spindle-shaped root, trifoliate leaves with oblong-lanceolate, rather obtuse leaflets, and long-peduncled, oblong, finally elongated spikes of purplish flowers; the legume is nearly orbicular and transversely wrinkled. The plant has a slight aromatic odor and a somewhat spicy and bitterish taste. It flowers in June and July, and should be collected when in full bloom.

P. ESCULENTA, *Pursh*, has a tuberous or turnip-shaped farinaceous edible root, which is known as *bread-root*, and likewise as *Indian turnip*, and formerly as *pomme blanche* and *pomme de prairie*. It grows on the prairies from Wisconsin to Missouri and westward.

P. GLANDULOSA, *Linné*, was formerly said to yield *yerba mate* (see page 810). It is a shrub of Chili, about 6 feet (1.8 M.) high, with rough glandular petioles, ovate-lanceolate, acute glandular leaflets, and white or blue flowers. The root is emetic, and the leaves have aromatic properties, their flavor resembling that of rue.

P. PENTAPHYLLA, *Linné*, of Mexico, has a thick root, which is sometimes known as *white contrayerva* from its color and medicinal properties.

P. BITUMINOSA, *Linné*, of Southern Europe, is suffruticose, and has a disagreeable bituminous odor.

P. CORYLIFOLIA, *Linné*, is indigenous to India and Arabia, has a whitish angular stem and simple ovate somewhat cordate and toothed, glandular leaves with short ovate ciliate stipules. The herb has a resinous, aromatic, and bitter taste, and, like the seeds known in India as *bauchee seeds*, is used as a tonic and in skin diseases.

Several other species of *Psoralea*, in addition to the two named above, are indigenous to the United States. They all appear to contain resin, volatile oil, tannin, and bitter principle, but have not been sufficiently analyzed.

Medical Action and Uses.—The leaves and the root have a bitter, pungent, and aromatic taste, which is most decided in the root. It has been described as a gentle, stimulating, and tonic nervine, and compared in its action to Chinese tea. It is said to have been used with advantage in chronic *diarrhœa* depending upon strumous conditions of the mesenteric glands, and in chronic *dyspepsia* attended with vomiting of blood. The medicine has been administered chiefly in the form of a tincture prepared with several other plants besides *Psoralea*, so that its special virtues cannot be extricated from the compound effect. The dose of the tincture is stated to be from 3 to 6 fluidrachms (Gm. 12-24) several times a day. As far as can be judged, it appears to partake of the qualities of aromatic and bitter tonics in general.

PTELEA.—SHRUBBY TREFOIL.

Hoptree, *Waferash*, E.; *Orme à trois feuilles*, Fr.; *Hopfenbaum*, *Kleebaum*, G.

Ptelea trifoliata, *Linné*.

Nat. Ord.—Rutacæ, Xanthoxylæ.

Description.—The hoptree is a handsome North American shrub growing southward and westward from New Jersey and Pennsylvania, chiefly, however, west of the Alleghanies, and is cultivated in Europe. The shrub is about 8 to 12 feet (2.4 to 3.6 M.) high, with dark-brown branches, which, like the leaves, are downy when young. The leaves are alternate, petiolate, light-green, and trifoliate, with sessile, pointed, indis-

tinely serrate, and finely pellucid-punctate leaflets, of which the lateral ones are obliquely ovate, and very uneven toward the base, the outer half being broadest, while the larger terminal one is elliptic or obovate and wedge-shaped at the base. They are from 3 to 5 inches (7 to 12 Cm.) long, when broken exhale a rather unpleasant odor, and have a bitter and somewhat astringent taste. The small greenish-white polygamous flowers are in compound terminal cymes, have a disagreeable odor, and are followed by a flat orbicular *fruit*, which is two-celled and two-seeded, and is surrounded by a circular membranous and slightly emarginate wing, the whole fruit being about $\frac{1}{2}$ inch (2 Cm.) in diameter and of a pleasant hop-like flavor. The fruit, leaves, and *bark of the root* have been employed. The latter is in fragments and irregular quills of a brown color, longitudinally wrinkled, lighter and smooth on the inner surface, breaks with a short fracture, and has a bitter and pungent taste.

Constituents.—G. M. Smyser (1862) found in the leaves *tannin* and *gallic acid*, in the fruit a soft acrid *resin*, and in the bark a reddish-brown *resin* soluble in ether and alcohol and of a pungent and acrid taste. All parts contain volatile oil and other principles commonly met with in plants. Justin Steer (1867) isolated *berberine* from the bark, and regards it as the bitter and tonic principle.

Allied Plant.—*PTELEA ANGUSTIFOLIA*, *Benth.*, a native of Colorado, has lanceolate pubescent leaves, and a smaller more deeply notched fruit than the preceding.

Medical Action and Uses.—The bark of the root appears to be aromatic and tonic, and has been used in tincture and infusion for *dyspepsia* and as a stimulant in *typhoid* febrile states. The leaves and young shoots have also been employed in strong infusion as anthelmintics. Of its administration we only know that a spirit made by macerating 6 ounces of the bark and $\frac{1}{2}$ ounce of ginger in 2 quarts of whiskey was prescribed in the *dose* of 1 or 2 tablespoonfuls (Gm. 16–32) three times a day. How much of the stimulant effects was due to the alcohol and how much to the ginger, and how much remained for the share of the trefoil, has not been estimated.

PULSATILLA, U. S.—PULSATILLA.

Pasque-Flower, E.; *Pulsatille*, *Coquelourde*, Fr.; *Küchenschelle*, G.

The flowering herb of *Anemone Pulsatilla*, *Linne* (s. *Pulsatilla vulgaris*, *Miller*), *Anemone* (*Pulsatilla*, *Miller*) *pratensis*, *Linne*, and of *Anemone* (*Pulsatilla*, *Miller*) *patens*, *Linne*, var. *Nuttalliana*, *Gray* (s. *An. Nuttalliana*, *De Candolle*, s. *An. Ludoviciana*, *Nuttall*). *Meehan*, *Nat. Flowers*, i. p. 49.

Nat. Ord.—*Ranunculaceæ*, *Anemoneæ*.

Origin.—The first two species are indigenous to the greater portion of Europe, and grow also in Siberia in sandy soil and in dry, open woodlands. The third species grows in similar localities from Central Europe eastward throughout Siberia, and in the western section of North America from Lake Superior south to Illinois, west to the Rocky Mountains, and north-westward into British America. The American plant differs slightly from the typical form of Eastern Europe. The section *Pulsatilla* differs from the other species of *Anemone* in having a narrowly-divided involucre, large flowers, and long feathery styles, which are permanent in the fruit. The plants flower early in spring, from March to May. They should be collected after the flowers have expanded, and should be carefully preserved and kept not longer than one year.

Description.—*A. pratensis* has a dark-brown, oblique, several-headed root, and pinnately two- or three-cleft, petiolate radical leaves with linear acute segments, and at the base surrounded by several ovate lanceolate sheaths. The flowering scape is about 6 inches (15 Cm.) high, and bears a single nodding bell-shaped flower reflexed at the apex, varying in color between dark-violet and light-blue, and surrounded by a distant sessile involucre composed of three palmately-divided and cleft bracts with linear lobes. The numerous ovaries are prolonged into a feathery tail (style). All herbaceous parts are clothed with long, soft, silky hairs, are nearly inodorous, but when rubbed exhale a very acrid vapor, and have a burning acrid taste. *A. Pulsatilla* closely resembles the former, but has the flowers erect and sepals spreading above, but not reflexed. *A. patens* has its purplish or whitish erect flowers developed before the leaves, which are twice or thrice deeply three-parted and have linear acute lobes.

Constituents.—The fresh plants of the section *Pulsatilla*, when distilled with water, yield a distillate from which ether extracts a very acrid yellow oil, which is gradually, or more rapidly in the presence of water, converted into *anemonin* and *anemonic acid*.

from which hot alcohol dissolves the former. Basiner (1881) found the yellow oil as well as the anemonin to be soluble in glacial acetic acid, from which solution they are removed by agitation with benzol. Anemonin, which was first observed by Störk (1771), and investigated by Heyer (1779), forms colorless friable crystals which are neutral, inodorous, and when fused exceedingly acrid, soluble in chloroform, nearly insoluble in ether and water; the composition of these crystals, according to Fehling (1841), is $C_{15}H_{12}O_6$. Löwig and Weidmann (1839) and Fehling (1841) observed that boiling baryta-water converts it into a brown amorphous acid. Anemonic acid, $C_{15}H_{14}O_7$, is a white crystalline tasteless powder insoluble in most simple solvents, and dissolves in alkalies with a yellow color. Similar results were obtained with American pulsatilla by A. W. Miller (1862) and F. E. Miller (1873).

The acrid oily principles of different species of *Ranunculus*, and probably of some other ranunculaceous plants, appear to be allied to, if not identical with, the above.

Pharmaceutical Preparation.—*EXTRACTUM PULSATILLÆ*. The expressed juice of the fresh flowering herb is heated, strained to remove albumen, evaporated to a small bulk, mixed with an equal measure of alcohol, filtered, and evaporated to the proper consistence.

Allied Plants.—Acrid properties resembling those of the preceding plants are met with in most species of *Anemone*, which are distinguished from the section *Pulsatilla* chiefly by the styles being much shorter and not feathery. *An. nemorosa*, *Linné*, *wind-flower* or *wood anemone*, a native of North America, Northern Asia, and Europe, has a long-petiolated trifoliate leaf with ovate or elliptic cut and toothed leaflets, an involucre of three similar leaves, and a white or purplish flower. *An. coronaria*, *Linné*, has been employed in the Levant, where it is indigenous; it is sometimes met with in gardens. *An. sylvestris* and *An. ranunculoides*, *Linné*, indigenous to Northern Asia and Europe, are used in Siberia. These species lose some of their acrid properties by drying and rapidly deteriorate on keeping.

AN. CERNUA, *Thunberg*. The root-stock is used in Japan and China under names signifying "white-headed old man." The root is about 4 inches (10 Cm.) long, about $\frac{1}{2}$ inch (4 Mm.) thick, unbranched, cylindrical, wrinkled, brittle, internally brown, with a central cavity lined with white tissue; it has a sweet and slightly acrid taste.

Physiological Action and Medical Uses.—Given to rabbits in the dose of from 5 to 10 grains, it reduces the pulse- and respiration-rate and the temperature, causes dyspnoea and stertor, debility, and then paralysis of the limbs, stupor, dilatation followed by contraction of the pupil, and death without convulsion. The characteristic lesions found on dissection are distension of the heart and great vessels, and of the veins of the brain and medulla oblongata, with dark blood (Clarus). The bruised fresh plant rubbed upon the skin irritates and may even vesicate it. The extract and tincture cause a sense of burning and numbness in the mouth. Internally, pulsatilla may inflame the stomach and bowels and cause fatal convulsions. In medicinal doses it is reported to act as a general excitant (Schroff). Anemonin applied to the tongue occasions a severe burning pain and persistently benumbs its sensibility. Internally, it acts as a general stimulant and a diuretic. Heyer (1779) related that an amaurotic patient who was taking about half a grain (Gm. 0.03) of anemonin twice a day experienced a dreadful sense of tension in the head and copious diuresis (Husemann).

Different species of anemone were recognized by ancient physicians as being identical in their medicinal power. According to Galen, the anemones are endowed with acrid, drawing, cleansing, and opening virtues. When chewed, anemone excites a secretion of mucus, its juice cleanses the brain and nostrils, and lessens or removes opacities of the cornea. It purifies foul ulcers, cures lepra and pityriasis, is emmenagogue and galactagogue. Neither Dioscorides, Pliny, nor the Arabians added anything to this enumeration, and the medicine seems to have been almost forgotten until the close of the eighteenth century. *Pulsatilla nigricans* was then highly praised by Störck and some of his contemporaries as an efficient remedy for *opacities of the cornea*, *cataract*, *paralysis*, *rheumatism*, *amenorrhœa*, *melancholy*, constitutional *syphilis*, old *ulcers*, and *scaly diseases of the skin*. In the last-named affections he held it to be peculiarly useful, generally prescribing the extract in doses of 1 or 2 grains, and gradually increasing them to 15 grains (Gm. 0.10–1). But subsequent observers of the best repute imitated Störck's practice without obtaining his results. The author who relates this history of Störck's use of the drug (Cazin) suggests that its more recent failures were due to the use of an improperly made extract. He refers to several physicians of previous generations who wrote of its singular efficacy in *whooping cough*, *visceral engorgements*, *gravel*, *comatose attacks*, and *obstructions of the nostrils*. Deniau used pulsatilla in several nervous disorders, and concluded

that the medicine is "a direct sedative of nervous irritability, but only indirectly a vascular sedative" (*Bull. de therap.*, civ. 81). By the greater number of recent writers on the materia medica the medicine is either wholly unnoticed or its virtues are described in accordance with the above history, which, it will be observed, assigns to it the characters of a panacea, so diverse and numerous are the diseases which it is reported to have cured. This list of incongruous diseases benefited by pulsatilla may be lengthened by *nervous headache* produced by overtaking the mind (Tucker), and by *dysmenorrhœa*, which in several cases was cured by 2 drops of a tincture of pulsatilla taken before meals for three days before the menstrual epoch (Piffard). The same physician reports that in *epididymitis* he administered 5-drop doses of the tincture with the effect of aggravating the inflammation, while he rapidly cured seven or eight cases of the disease by doses of "one-tenth of a minim well diluted, and administered every two or three hours." No other treatment was employed. Similar statements have been made by Sturgis (*Med. News*, xlii. 267). From this summary it may fairly be concluded that pulsatilla is either a remedy of extraordinary and incomprehensible power, or that the reporters of its cures have been misled by their imagination or a neglect of the precautions necessary in studying the virtues of medicines.

The powdered herb was formerly prescribed in doses of 4 or 5 grains (Gm. 0.25–0.30), and an infusion made with 1 drachm of the fresh plant in 3 ounces of wine or water (Gm. 4 in Gm. 100) was given during the day in divided doses. The alcoholic extract may be used in doses of from $\frac{1}{2}$ grain to 3 grains (Gm. 0.03–0.20). Anemonin is directed in doses of from $\frac{1}{4}$ to $\frac{1}{2}$ gr. (Gm. 0.01–0.03) in pilular form. A tincture, also made from the fresh plant, is prescribed in doses of from 3 to 10 drops (Gm. 0.20–0.60) several times a day.

THALICTRUM MACROCARPUM furnishes an alkaloid, thalicttrin, and also macrocarpin, of which the former only seems to produce definite physiological effects. Rochefontaine and Doassans state that its extract kills a frog in the dose of gr. $\frac{1}{2}$ to $\frac{1}{4}$ (Gm. 0.02–0.03); that its sulphate or muriate is fatal to the same animal in the dose of gr. $\frac{1}{32}$ to $\frac{1}{16}$ (Gm. 0.002–0.005); and that when injected into the vein of a dog it caused death in the dose of gr. xv. to gr. xxii. (Gm. 1–1.50). Subcutaneously, twice the latter dose was required to kill. In frogs thalicttrin destroys voluntary and then reflex movement, and after rendering the heart irregular arrests it in diastole. In dogs it first produces a state of somnolence and inertness, with vomiting, purging, and micturition; the blood-pressure declines and general sensibility is abolished; the heart beats vigorously, although the pulse becomes hurried and feeble and the respiration frequent and full. A convulsion follows, the pupils dilate, and the heart, and then the respiration, cease (*Archives gén.*, Juill., 1880, p. 368; *Practitioner*, xxvii. 214).

PULVERES.—POWDERS.

Poudres, Fr.; *Pulver*, G.

Preparation.—All solid drugs may be reduced to powder, but the means by which pulverization is effected must vary very considerably according to the nature of the drug. The large majority of crystallized chemical compounds are readily powdered by *trituration* in a porcelain or Wedgewood mortar; many of those which are insoluble or sparingly soluble in alcohol may be powdered by *precipitating* them from their concentrated solution by pouring it slowly and with continual agitation into alcohol. Compounds which are insoluble in water may frequently be obtained in a more or less fine powder, which is either amorphous or crystalline, by means of double decomposition and *precipitation*. Soluble compounds may also be powdered by evaporating their solution, and, as it thickens, by stirring it continually, so as to disturb crystallization or prevent the compound from separating as a solid mass. This process is termed *granulation*, and is equally applicable to fusible substances, which, after having been liquefied by heat, are stirred or triturated while they are cooling and congealing. Volatile compounds and elements (calomel, sulphur, etc.) may be finely powdered by *sublimation*, and by suddenly condensing their hot vapors in a large chamber with a current of air, or, if insoluble in water, with a current of steam.

In several of these processes the powder is not obtained of uniform fineness, and then requires to be *sifted*, or the finer particles are separated from the coarser by means of *elutriation*, which process consists in diffusing the powder in water and decanting from the

heavy sediment. The fine powder, which remains longest in suspension, is then permitted to subside, and, after withdrawing the liquid, dried. It is evident that only those substances are adapted to this treatment which are heavier than water, and which are entirely insoluble therein; elutriation is usually preceded by *levigation*, which is simply a process of trituration in the presence of sufficient moisture to render the mass soft. The operation is performed either in a mortar or upon a slab by the aid of a muller.

Drugs which are composed of vegetable tissue or which consist of exudations cannot, as a rule, be reduced to powder by these means. In these cases *contusion* is required, and this is the method most frequently employed. The substance is placed in a rather deep mortar, and broken by perpendicular strokes with the flattened surface of a heavy pestle. The process is called *bruising* if the substance is to be broken merely into a coarse powder. If the drug contains a certain amount of oil or resin, the heat produced by the pounding will often render the material more or less soft or adhesive. This result is best prevented by exposing the drug to a low temperature and powdering in the cold, when it will retain its pulverulent condition at ordinary temperatures, or, if it conglomerates, it may be rubbed into powder by slight trituration. Mortars made of iron or brass are best adapted for preparing powders by contusion. Some tough materials are conveniently reduced to powder by *rasping*.

Most of the vegetable powders are, however, prepared on a large scale at the drug-mills by *grinding*, the grinding surface being a bed of hard stone upon which either iron balls or millstones are made to revolve. A draught is thereby created which carries the fine powder up to a certain height, and if this alone is collected it is called a *dusted powder*. Oily seeds and similar material cannot profitably be powdered in this manner, because by the pressure and heat created by the grinding the oil rises to the surface and agglutinates a part of the powder. Such material is best ground, or rather cut, between horizontal millstones suitably prepared for the purpose. A number of drug-mills which may be worked by hand have been constructed, and serve a good purpose for the use of the pharmacist in preparing the coarser kind of powders, but none have been made which could be used with advantage for finely powdering moderate quantities.

Whether contusion or grinding is resorted to, the drugs to be powdered should be deprived of the moisture remaining in them by exposing them in a drying-room to a temperature of about 50° C. (122° F.). Drugs, however, which owe their virtues to volatile oil, and which should be powdered in the air-dry condition or on a small scale, are conveniently dried over burnt lime. The different tissues of plants are not reduced to powder with equal facility; the fibro-vascular bundles and the bast-fibres are usually more refractory than parenchyma-tissue, and more or less of the former generally remains behind as a coarse powder. When the powder is intended to be exhausted by percolation or otherwise, the coarse particles are utilized with the fine powder; but in case the latter be intended for dispensing, the coarser portion is removed by a sieve. The fine powder which may be sifted off from time to time during the process of powdering should be carefully mixed to ensure uniformity in composition. The fibrous portion of vegetable drugs is usually less active than the remainder, and if in such a case the whole of it be rejected, the resulting powder must necessarily be stronger than the crude drug from which it has been prepared; thus, if the bark of ipecacuanha-root be separated from the wood and powdered by itself, such powdered ipecacuanha will possess an activity about 20 per cent. greater than the root itself.

Fineness of Powders.—The United States Pharmacopœia designates five degrees of fineness—namely, *very fine*, when passed through a sieve of eighty or more meshes to the linear inch; *fine*, when passed through one of sixty meshes; *moderately fine*, through one of fifty meshes; *moderately coarse*, through one of forty meshes; and *coarse*, if passed through a sieve of twenty meshes to the linear inch. The fineness of powders is often conveniently described as being No. 20, etc., indicating that it has been passed through a sieve of that size (see page 605).

Compound Powders.—Since nearly all solid drugs may be obtained and kept in the state of powder, the pharmacopœias give special directions only for those powders which are composed of two or more ingredients. In preparing these it is generally advisable to reduce each substance separately to powder; the powders are then weighed out and mixed in a mortar, or are passed repeatedly through a suitable sieve. Some special observations will be made in connection with several official powders.

Dispensing of Powders.—In the majority of cases when powders are prescribed the ingredients are such as are kept on hand pulverized or in such a condition that they may be easily powdered by trituration in a mortar. The latter ingredients are then

weighed out first, and rubbed fine before the powders are added. Should soft substances, such as extracts, or liquids, such as volatile oils, be directed, they are triturated with the sugar which usually is a constituent of magistral powders until reduced to powder, when the other articles are added and well mixed. In most cases, perhaps, it will be of advantage not to use finely-powdered sugar, but to employ sugar in small lumps, which, while being rubbed to powder in the presence of the other ingredients, will tend to cause their still greater subdivision through the prolonged attrition. There are, however, occasional exceptions to the procedure as described, for in consequence of the elevation of temperature produced by the trituration chemical processes are likely to be induced which would interfere with the stability of the powder; such instances are the mixing of oxidizing agents like chlorate of potassium with vegetable substances, which under the pressure of the pestle would cause an explosion; or the mixing of salts, which in the presence of a little moisture would result in liquefaction, as in triturating together acetate of lead and sulphate of zinc. Compound powders of this nature ought invariably to be made by powdering the constituents separately in a mortar; if necessary, they should then be well dried, and finally mixed upon smooth paper with the aid of a spatula, without exerting any friction.

Powders are rarely prescribed in bulk, except when intended for external use; in nearly all cases they are divided by the pharmacist, each dose being dispensed in a separate paper. Deliquescent and odorous powders are best dispensed in waxed paper (see p. 421).

Administration.—Powders are generally taken suspended in water or in a liquid flavored with syrup or some pleasant aromatic. The nauseous taste will not always thus be disguised. To remedy this difficulty it has been customary in some countries to envelop the powder in a wafer of sufficient size and soften this by a brief immersion in water, when it may be swallowed without any inconvenience. *Cachets de pain*, or *wafer-capsules*, an elegant modification of this process, were introduced by M. Limousin (1873). The sheet wafer is punched into circular disks; these are dampened, and then pressed between two warmed plates of the desired shape, whereby they become concave on one side. A dose of the powder is placed on this side, the margin is very slightly dampened, and an empty disk is placed upon and fastened to it by sufficient pressure. Various apparatuses have been suggested for sealing the wafers. In taking such a wafer-capsule it is first dipped in water for a moment, then at once placed upon the back part of the tongue, and swallowed with a draught of water or other suitable liquid. Nauseous powders of small bulk are conveniently administered in unsealed gelatin-capsules, one of which is slipped over the open end of another one containing the powder (see page 725).

Granular Powders.—These are made in various ways. A method of granulating vegetable and similar powders was suggested by Dr. Thomas Skinner (1862), and is executed by triturating the powder with sufficient mucilage until a crummy non-adhesive mass is obtained, which is dried in thin layers, bruised, and separated by sieves into powders as desired; these granules may then be covered with tolu in the same manner as pills. Various saline mixtures, usually of an effervescing nature, have been granulated by powdering separately citric or tartaric acid, sugar, bicarbonate of sodium, carbonate of magnesium, etc., mixing them together by sifting, adding sufficient strong alcohol to render the mixture slightly damp and adherent, and rubbing with slight pressure through a No. 8 or other suitable sieve. After drying, the granules of the different sizes are separated by suitable sieves.

Preservation.—When perfectly free from moisture, vegetable powders may be preserved in hermetically-sealed vessels; but since they attract moisture on occasional exposure, it is much better to keep them in a dry place enclosed in vessels which will admit the air but exclude the light. As a rule, such powders will be found to keep well in good paper boxes unless they contain volatile oil.

PULVIS AMYGDALÆ COMPOSITUS, *Br.*—COMPOUND POWDER OF ALMONDS.

Confectio amygdalæ, Conserva amygdalarum.—*Confection of almond, E.; Conserve d'amandes, Fr.; Mandelconserve, G.*

Preparation.—Take of Sweet Almonds 8 ounces; Refined Sugar, in powder, 4 ounces; Gum-Acacia, in powder, 1 ounce. Steep the almonds in warm water until their skins can be easily removed, and when blanched dry them thoroughly with a soft cloth and rub them lightly in a mortar to a smooth consistence. Mix the gum and the sugar.

and, adding them to the pulp gradually, rub the whole to a coarse powder. Keep it in a lightly-covered jar.—*Br.*

Medical Uses.—The compound powder of almonds serves for the convenient preparation of the almond mixture when mixed with water in the proportion of $2\frac{1}{2}$ ounces to a pint (Gm. 75 in Gm. 500).

PULVIS ANTIMONIALIS, *U. S.*, *Br.*—ANTIMONIAL POWDER.

Pulvis antimonii compositus, Pulvis Jacobi.—James's powder, *E.*; *Poudre antimoniale de James, Fr.*; James's Antimonpulver, *G.*

Preparation.—Oxide of Antimony 33 parts (330 grains); Precipitated Phosphate of Calcium 67 parts (670 grains); to make 100 parts (1000 grains). Mix them intimately.—*U. S.*

Take of oxide of antimony 1 ounce; phosphate of calcium 2 ounces. Mix them thoroughly.—*Br.*

Antimonial powder has been recently admitted into the *U. S. P.*, and is practically identical with that of the *Br. P.* It is intended as a simplified substitute for a nostrum which has enjoyed considerable reputation in Great Britain and elsewhere for more than a hundred years. Another formula, formerly recognized as yielding a good substitute, requires the ignition of a mixture consisting of 1 part of sulphuret of antimony and 2 parts of horn shavings by throwing this in small quantities into a red-hot crucible, powdering the product, and keeping again for some time at a red heat.

A somewhat similar preparation is known here as *Tyson's antimonial powder*, of which two kinds are sometimes employed. One, designated as No. 1, consists of oxide of antimony 10 parts and phosphate of calcium 90 parts. No. 2 is made by triturating oxide of antimony 10 parts and sulphate of potassium 45 parts into a fine powder, and adding 45 parts of phosphate of calcium.

Medical Action and Uses.—Antimonial powder acts in virtue of the oxide of antimony it contains, the phosphate of lime serving only to divide it minutely. Its action is essentially the same as that of tartar emetic, but slower in consequence of its inferior solubility. It is therefore less apt to act as an emetic than as a diaphoretic in febrile states. It may be given in doses of from 3 to 15 grains (Gm. 0.20–1).

PULVIS AROMATICUS, *U. S.*—AROMATIC POWDER.

Pulvis cinnamomi compositus, Br.—Compound powder of cinnamon, *E.*; *Poudre des épices, P. des aromates, Poudre aromatique, Fr.*; *Gewürzpulver, Aromatisches Pulver, G.*

Preparation.—Cinnamon, in No. 60 powder, 35 parts (7 oz.); Ginger, in No. 60 powder, 35 parts (7 oz.); Cardamom, deprived of the capsules and crushed, 15 parts (3 oz.); Nutmeg, in No. 20 powder, 15 parts (3 oz.); to make 100 parts (20 oz.). Rub the cardamom and nutmeg with a portion of the cinnamon until reduced to a fine powder; then add the remainder of the cinnamon and the ginger, and rub them together until they are thoroughly mixed.—*U. S.*

Grated as finely as possible, the nutmeg is gradually added, with constant trituration, to the crushed cardamom-seed and a portion of the powdered cinnamon, and afterward mixed with the remaining powders. The British Pharmacopœia omits the nutmeg, and directs powdered cinnamon, cardamom, and ginger, of each 1 ounce, to be thoroughly mixed, sifted, and lightly rubbed in a mortar.

Pharmaceutical Preparations.—CONFECTIO AROMATICA, Electuarium aromaticum.—Aromatic confection, *E.*; Electuaire (Confection) aromatique, *Fr.*; Aromatische Latwerge, Gewürzlatwerge, *G.*—Rub aromatic powder 4 ounces with clarified honey 4 ounces or a sufficient quantity, until a uniform mass of the proper consistence is obtained.—*U. S.* 1870.

The absorption of the moisture by the vegetable tissue will render this confection gradually crummy, and necessitate the further addition of honey. If properly prepared, it will, though dry in appearance, become pliable and adhesive under the pestle.

Off. Prep.—Extractum aromaticum fluidum, *U. S.*

Medical Action and Uses.—Aromatic powder may be given internally for the relief of nausea, flatulence, colic, or diarrhœa, in the dose of 10 grains (Gm. 0.66) and upward, for which purposes it should be mixed with syrup. The now disused aromatic confection was similarly employed. The powder is an excellent stimulant and anodyne in the cases named when it is applied enclosed in a flannel bag and saturated with a hot alcoholic liq-

uor. In this way it is singularly efficient in allaying nausea and colic. Laudanum may be added to it in appropriate cases. Care should be taken to protect the linen from its stain, which is indelible. Instead of the officinal ingredients of this aromatic fomentation, the following will be found more efficient: equal parts of powdered cinnamon, ginger, allspice, and cloves, to which some add black pepper.

PULVIS CATECHU COMPOSITUS, *Br.*—COMPOUND POWDER OF CATECHU.

Preparation.—Take of Pale Catechu, in powder, 4 ounces; Kino, in powder, Rhatany-Root, in powder, each 2 ounces; Cinnamon-Bark, in powder, Nutmeg, in powder, each 1 ounce. Mix them thoroughly, pass the powder through a fine sieve, and finally rub it lightly in a mortar. Keep it in a stoppered bottle.—*Br.*

Medical Uses.—This powder is especially useful in *diarrhea* produced by debility or by cold after fever has subsided. *Dose*, from 10 grains to a drachm (Gm. 0.60–4).

PULVIS CRETÆ AROMATICUS, *Br.*—AROMATIC POWDER OF CHALK.

Confectio aromatica, Lond.—*Poudre de craie aromatique*, Fr.; *Gewürztes Kreidepulver*, G.

Preparation.—Take of Cinnamon-Bark, in powder, 4 ounces; Nutmeg, in powder, Saffron, in powder, each 3 ounces; Cloves, in powder, $1\frac{1}{2}$ ounces; Cardamom-Seeds, in powder, 1 ounce; Refined Sugar, in powder, 25 ounces; Prepared Chalk 11 ounces. Mix them thoroughly, pass the powder through a fine sieve, and finally rub it lightly in a mortar. Keep it in a stoppered bottle.—*Br.*

Medical Uses.—Aromatic powder of chalk is an excellent preparation for the cure of accidental *diarrheas* produced by cold, or even by crude ingesta, provided that the offending substance has been discharged. As the symptoms corrected by chalk and those relieved by the aromatic powder are in a great measure independent of each other, the proportion of these ingredients should vary, and hence their association in fixed proportion and in an officinal formula is unnecessary. The *dose* of the preparation is from 30 to 60 grains (Gm. 2–4).

PULVIS CRETÆ AROMATICUS CUM OPIO, *Br.*—AROMATIC POWDER OF CHALK AND OPIUM.

Poudre de craie opiacée, Fr.; *Kreidepulver mit Opium*, G.

Preparation.—Take of Aromatic Powder of Chalk $9\frac{3}{4}$ ounces; Opium, in powder, $\frac{1}{4}$ ounce. Mix them thoroughly, pass the powder through a fine sieve, and finally rub it lightly in a mortar. Keep it in a stoppered bottle.—*Br.*

Medical Uses.—This preparation is the same as the last, except that it contains 1 grain of opium in every 40 grains of the powder. It is therefore more efficient in the same class of cases. From 10 to 20 grains (Gm. 0.60–1.30) may be given at a *dose*.

PULVIS CRETÆ COMPOSITUS, *U. S.*—COMPOUND CHALK POWDER.

Poudre de craie composée, Fr.; *Kreidepulver mit Gummi*, G.

Preparation.—Prepared chalk 30 parts (3 oz.); Acacia, in fine powder, 20 parts (2 oz.); Sugar, in fine powder, 50 parts (5 oz.); to make 100 parts (10 oz.). Mix them intimately.—*U. S.*

This has been introduced with the view of preparing from it the chalk mixture as wanted.

Off. Prep.—Mistura cretæ, *U. S.*

Dose, from 20 to 60 grains (Gm. 1.30–4).

PULVIS EFFERVESCENS COMPOSITUS, *U. S.*—COMPOUND EFFERVESCING POWDER.

Pulveres effervescentes aperientes, *U. S.* 1870; *Pulvis ætrophorus laxans*, s. *P. ætrophorus Seydlitzensis*, P. G.—*Aperient effervescing powders*, *Seydlitz powders*, E.; *Poudre gazeuse purgative*, *Poudre de Sedlitz*, Fr.; *Abführendes Brausepulver*, *Seydlitzpulver*, G.

Preparation.—Bicarbonate of Sodium, in fine powder, 480 grains (31 Gm.); Tar-

trate of Potassium and Sodium, in fine powder, 1440 grains (93 Gm.); Tartaric Acid, in fine powder, 420 grains (27 Gm.). Mix the bicarbonate of sodium intimately with the tartrate of potassium and sodium, and divide the mixture into 12 equal parts. Then divide the tartaric acid into 12 equal parts. Lastly, keep the parts, severally, of the mixture and of the acid in separate papers of different colors.—*U. S.*

The alkaline powder is usually put into a blue paper, each containing of sodium bicarbonate 40 grains or 2.58 Gm. (2.5 Gm. *P. G.*; 2.0 Gm. *F. Cod.*), and of potassium and sodium tartrate 120 grains or 7.75 Gm. (7.5 Gm. *P. G.*; 6 Gm. *F. Cod.*). The tartaric acid is wrapped in white paper, and weighs 35 grains or 2.25 Gm. (2.0 Gm. *F. Cod.*, *P. G.*). On mixing the solutions of the contents of the two papers, Mr. Wm. Gilmour (1881) observed the formation of potassium bitartrate even in the presence of insufficient tartaric acid for producing neutral sodium tartrate; this effect is due to the liberated carbonic acid.

Allied Preparations.—*PULVERES EFFERVESCENTES*, *U. S.* 1870: *Pulvis aërophorus anglicus*, *P. G.*—Effervescing powders, Soda powders, *E.*: *Poudre gazeuse*, *P. gazogène*, *P. aërophore*, *P. de Seltz*, *Fr.*; *Englisches Brausepulver*, *G.*—Take of bicarbonate of sodium, in fine powder 360 grains; tartaric acid, in fine powder, 300 grains. Divide each of the powders into 12 equal parts, and keep the parts, severally, of the bicarbonate and of the acid in separate papers of different colors.

PULVIS AEROPHORUS, *P. G.*, is composed of 10 parts of bicarbonate of sodium, 9 parts of tartaric acid, and 19 parts of white sugar. Each substance is finely powdered and well dried before the three are mixed, when the powder may be kept unaltered in well-closed vessels. But if these are opened, and from the deposition of moisture decomposition begins to take place, the change proceeds more rapidly in a closed than in an open vessel should the latter be kept in a dry and airy place. The powder keeps much better if granulated as described above. Either form of powder may serve as a vehicle for the convenient and pleasant administration of other medicines, such as salts of iron, quinine, etc., which should not be mixed with the bicarbonate of sodium alone.

(See this subject treated in *Proceedings Amer. Phar. Assoc.*, 1856, p. 49.)

Medical Action and Uses.—The compound effervescing powder is convenient for administering tartrate of potassium and sodium in a state of effervescence. The acid powder should be dissolved in 1 or 2 fluidounces, and the saline in about 6 fluidounces, of water; the liquids should then be gradually mixed and drunk while effervescing. Seidlitz powders are very commonly employed to relieve moderate constipation and the feverishness that attends the first stage of many slight disorders, especially those produced by "taking cold" or by an imprudent and excessive use of food and alcohol. Like other saline laxatives, this one is more appropriate in warm than in cold weather. If a very active operation is desired, one and a half or even two pairs of powders may be given at once, or, on the other hand, they may be administered in divided portions as a febrifuge medicine.

The carbonic acid disengaged during the administration of soda powders is a direct stimulant to the stomach and nervous system, while it creates an agreeable sense of coolness in the abdomen. The tartrate of sodium formed in the process is diuretic, antacid, and slightly laxative, and probably during fever is diaphoretic also. Soda powders are much used to relieve the feverish effects of imprudent eating and to remove constipation. Each powder should be dissolved in about 4 ounces (Gm. 120) of water flavored with syrup if preferred, and the solutions, being mixed, should be taken while effervescing.

PULVIS ELATERINI COMPOSITUS, *Br.*—COMPOUND POWDER OF ELATERIN.

Preparation.—Take of Elaterin 5 grains; Sugar of Milk 195 grains. Rub them together in a mortar until they are reduced to fine powder and intimately mixed.—*Br.*

Medical Action and Uses.—This preparation is a convenient one for the administration of elaterin. *Dose*, from $\frac{1}{2}$ grain to 5 grains (Gm. 0.03–0.33).

PULVIS GLYCYRRHIZÆ COMPOSITUS, *U. S.*, *Br.*—COMPOUND POWDER OF GLYCYRRHIZA (LIQUORICE).

Pulvis liquiritiæ compositus, *s. P. pectoralis Kurellæ*, *P. G.*—*Poudre pectorale*, *Poudre de réglisse composée*, *Fr.*; *Brustpulver*, *G.*

Preparation.—Senna, in No. 60 powder, 18 parts (90 grains); Glycyrrhiza, in No. 60 powder, 16 parts (80 grains); Fennel, in No. 60 powder, 8 parts (40 grains); Washed

Sulphur 8 parts (40 grains); Sugar, in fine powder, 50 parts (250 grains): to make 100 parts (500 grains). Rub them together until they are thoroughly mixed.—*U. S.*

Powdered senna 2 parts; powdered liquorice-root 2 parts; powdered fennel 1 part; washed sulphur 1 part; powdered sugar 6 parts.—*P. G., Br.*

The first formula has been adapted from that of the German Pharmacopœia, and is practically identical with it and with that of the British Pharmacopœia. The powder is of a greenish-yellow color. The British Pharmacopœia of 1867 omitted the fennel and sulphur.

Medical Action and Uses.—This preparation is a mild but efficient aperient in the *dose* of from 30 to 60 grains (Gm. 2–4). A better form of it is essentially that of the German Pharmacopœia, and is composed as follows: *℞.* Senna, liquorice-root, in fine powder, of each $\mathfrak{z}\text{ij}$; fennel-seed, washed sulphur, in fine powder, of each $\mathfrak{z}\text{ss}$; white sugar, in fine powder, $\mathfrak{z}\text{ij}$. Mix thoroughly, pass through a fine sieve, and rub lightly in a mortar. *S.*—A teaspoonful in a glass of water at bedtime for the relief of habitual constipation.

PULVIS IPECACUANHÆ ET OPII, *U. S.*—POWDER OF IPECAC AND OPIUM.

Pulvis ipecacuanhæ compositus, *U. S.* 1870, *Br.*; *Pulvis ipecacuanhæ opiatius*, *s. Pulvis Doveri*, *P. G.*—Compound powder of ipecacuanha, *Dover's powder*, *E.*; *Poudre de Dover*, *Fr.*; *Dover'sches Pulver*, *G.*

Preparation.—Ipecac, in No. 60 powder, 10 parts (50 grains); Powdered opium 10 parts (50 grains); Sugar of Milk, in No. 30 powder, 80 parts (400 grains); to make 100 parts (500 grains). Rub them together into a very fine powder.—*U. S.*

In this formula the milk-sugar is directed to be used in a rather coarse powder; the fragments of the crystals, being very hard, serve to grind the vegetable powders still finer during the necessarily prolonged trituration. The German Pharmacopœia orders the same ingredients in the same proportions as given above, but directs all three to be separately very finely powdered, and then to be intimately mixed. Both these pharmacopœias have, without any urgent reason, substituted milk-sugar in the place of potassium sulphate, which was formerly employed in the same proportion, and is still ordered by the British Pharmacopœia. Both powders are of a pale-brown color and have the odor of opium, somewhat modified by that of ipecac; they differ but slightly in taste, that of the *Br. P.* being somewhat saline in addition to the bitter and nauseous taste of the other ingredients, which predominates in the powder prepared by the above formula. The *Dover's powder* of the French Codex is nearly the same as that originally used by Dr. Dover, the chief difference being the substitution of dry extract of opium for opium: it is composed of sulphate and nitrate of potassium, each 40 parts, and dry extract of opium, ipecacuanha, and liquorice-root, each 10 parts, the whole to be made into a homogeneous powder.

Medical Action and Uses.—*Dover's powder* contains in every 10 grains 1 grain each of opium and ipecacuanha and 8 grains of sugar of milk. Its physiological effects are sleep and diaphoresis. The latter is perhaps favored by the ipecacuanha, but is essentially produced by the opium. If *Dover's powder* has the advantage of readily causing diaphoresis, it has the disadvantage of sometimes producing nausea and leaving the mouth more pasty than opium does alone.

This preparation is of peculiar value in the forming stages of muscular rheumatism, for if it occasions sweating it often terminates the attack. The use of hot drinks about an hour after the powder is administered will greatly promote its operation. A similar statement may be made of its use at the commencement of acute inflammations, such as coryza, sore throat, laryngitis, bronchitis, pleurisy, pneumonia, etc. It is of use in hæmorrhage from internal organs, and especially from the uterus; in diarrhœa from transient causes or from intestinal disease, as in typhoid fever, tuberculosis, dysentery, etc.; in profuse sweats from phthisis or other debilitating causes. It has been recommended in diabetes, Bright's disease, and calculous affections, but in them it is less appropriate than opium alone.

The ordinary *dose* of *Dover's powder* is 10 grains (Gm. 0.60), but in many cases doses only half as large, and repeated at longer or shorter intervals, are preferable. When full diaphoresis is desired the dose may be 15 or 20 grains (Gm. 1–1.30), and its operation may be promoted by hot drinks, thick bed-clothes, etc.

PULVIS JALAPÆ COMPOSITUS, U. S., Br.—COMPOUND POWDER OF JALAP.

Pulvis jalapæ tartaratus, Pulvis catharticus.—*Poudre de jalap composée*, Fr.; *Jalapenpulver mit Weinstein*, G.

Preparation.—Take of Jalap, in No. 60 powder 35 parts (175 grains), Bitartrate of Potassium, in fine powder, 65 parts (325 grains); to make 100 parts (500 grains). Rub them together until they are thoroughly mixed.—*U. S.*

Take of jalap, in powder, 5 ounces; acid tartrate of potash 9 ounces; ginger, in powder, 1 ounce. Mix them thoroughly, pass the powder through a fine sieve, and finally rub it lightly in a mortar.—*Br.*

Medical Action and Uses.—This is an efficient hydragogue cathartic, particularly applicable to cases of hepatic and splenic obstruction with abdominal *dropsy*, and to other forms of dropsy in which the amount of the effusion constitutes an immediate source of danger. In the latter case the proportion of the bitartrate should be increased from 60 to 120 grains, and of the jalap to 10 or 15 grains. The *dose* of the compound powder of jalap is from 10 to 30 grains (Gm. 0.60–2).

PULVIS KINO COMPOSITUS, Br.—COMPOUND POWDER OF KINO.

Pulvis kino cum opio.—*Poudre de kinoopiacée*, Fr.; *Kinopulver mit Opium*, G.

Preparation.—Take of Kino, in powder, 3½ ounces; Opium, in powder, ¼ ounce; Cinnamon-Bark, in powder, 1 ounce. Mix them thoroughly, pass the powder through a fine sieve, and finally rub it lightly in a mortar. Keep in a stoppered bottle.—*Br.*

Medical Action and Uses.—This preparation is one of the many in which opiates and astringents are associated, and which are chiefly used in cases of excessive *gastric* or *intestinal secretion*, including *diarrhœa*; it is also employed in the various *dyspeptic* derangements for which kino itself is used, and for lessening the secretion of urine in *diabetes* and of perspiration in various forms of *hectic fever*. The *dose* is from 5 to 20 grains (Gm. 0.30–1.30).

PULVIS MORPHINÆ COMPOSITUS, U. S.—COMPOUND POWDER OF MORPHINE.

Pulvis camphoræ compositus Tully.—*Tully's powder*, E.; *Poudre de Tully*, Fr.; *Tully'sches Pulver*, G.

Preparation.—Sulphate of Morphine 1 part (3 grains); Camphor 20 parts (60 grains); Glycyrrhiza, in No. 60 powder, 20 parts (60 grains); Precipitated Carbonate of Calcium 20 parts (60 grains); Alcohol a sufficient quantity. Rub the camphor with a little alcohol, and afterward with the glycyrrhiza and precipitated carbonate of calcium, until a uniform powder is produced. Then rub the sulphate of morphine with this powder, gradually added, until the whole is thoroughly mixed.—*U. S.*

This formula originated with Dr. William Tully of New Haven, Con. The powder should be very carefully prepared, so that the morphine salt may be uniformly incorporated with the other ingredients. Owing to the volatilization of camphor, it is best to prepare the powder in a small quantity only, and to preserve it in a well-stopped bottle kept in a cool place.

Medical Action and Uses.—The evaporation of the camphor from this powder causes it to deteriorate constantly, and therefore to cease to be what it originally was. Doubtless, the combination of camphor and opium, as it is constantly used in nervous affections, with different proportions of the two ingredients, is a most valuable one, and is recognized as such in the ancient liquid preparation paregoric elixir. The addition to ordinary Dover's powder of whatever dose of camphor may be required for individual cases appears to us preferable to so unstable a preparation as this. The *dose* of it may be stated at from 5 to 10 grains (Gm. 0.30–0.60).

PULVIS OPII COMPOSITUS, Br.—COMPOUND POWDER OF OPIUM.

Preparation.—Take of Opium, in powder, 1½ ounces; Black Pepper, in powder, 2 ounces; Ginger, in powder, 5 ounces; Caraway-Fruit, in powder, 6 ounces; Tragacanth, in powder, ½ ounce. Mix them thoroughly, pass the powder through a fine sieve, and finally rub it lightly in a mortar. Keep in a stoppered bottle.—*Br.*

This powder contains 10 per cent. of powdered opium.

Medical Uses.—This powder contains the ingredients, in a dry state, of the confection of opium, and may be used for the same purposes. *Dose*, from 2 to 5 grains (Gm. 0.10–0.30).

PULVIS RHEI COMPOSITUS, *U. S., Br.*—COMPOUND POWDER OF RHUBARB.

Pulvis magnesia cum rheo, s. *P. infantum*, s. *P. antacidus*, *P. G.*—*Magnesia and rhubarb*, *Gregory's powder*, *E.*; *Poudre de rhubarbe composée*, *Fr.*; *Kinderpulver*, *G.*

Preparation.—Take of Rhubarb, in No. 60 powder, 25 parts (2½ oz.); Magnesia 65 parts (6½ oz.); Ginger, in No. 60 powder, 10 parts (1 oz.); to make 100 parts (10 oz.). Rub them together until they are thoroughly mixed.—*U. S.*

The British Pharmacopœia has adopted Dr. Gregory's formula: powdered rhubarb 2 oz., light magnesia 6 oz., powdered ginger 1 oz.; the mixed powder is to be passed through a fine sieve. Mr. Gilmour (1881) observed that in order to render this powder readily miscible with water the rhubarb and ginger should first be triturated with about 5 per cent. of magnesium carbonate, and the calcined magnesia afterward added.

The formula of the German Pharmacopœia is as follows: carbonate of magnesium, 60 parts; oil-sugar of fennel (1 drop of oil of fennel to 2 Gm. of sugar) 40 parts; powdered rhubarb 15 parts. *Mix.*

These powders, when freshly prepared, have a yellowish color, but on keeping gradually assume a reddish tint from the absorption of moisture and the reaction of the magnesia with the constituents of rhubarb; in the presence of water or of alcohol they become deep-red.

Medical Action and Uses.—There does not appear to be any reason for the existence of this compound powder, the ingredients of which may very well be mixed extemporaneously in proportions adapted to the peculiarities of each case. It is a good laxative in cases of acid *dyspepsia* with constipation, and of *diarrhœa* with acid stools, especially as it is apt to occur in children. The *dose* for an adult is from 20 to 60 grains (Gm. 1.30–4), and for a child from 5 to 10 grains (Gm. 0.30–0.60).

PULVIS SCAMMONII COMPOSITUS, *Br.*—COMPOUND POWDER OF SCAMMONY.

Preparation.—Scammony Resin, in powder, 4 ounces; Jalap, in powder, 3 ounces; Ginger, in powder, 1 ounce. Mix them thoroughly, pass the powder through a fine sieve, and finally rub it lightly in a mortar.—*Br.*

Medical Action and Uses.—The close resemblance of scammony to jalap in its mode of action in all useful respects, and its harsh and irritating operation in others, render the conjunction of the two purgatives apparently superfluous. It is possible, however, that cases may occur in which the ruder action of scammony upon the bowels may be useful as a derivant from the brain. The *dose* of the powder is from 10 to 20 grains (Gm. 0.60–1.20).

PULVIS TRAGACANTHÆ COMPOSITUS, *Br.*—COMPOUND POWDER OF TRAGACANTH.

Preparation.—Take of Tragacanth, in powder, Gum-Arabic, in powder, Starch, in powder, each 1 ounce; Refined Sugar, in powder, 3 ounces. Rub them well together.—*Br.* It is a white powder, having a sweet, mucilaginous taste.

PULVIS GUMMOSUS, *P. G.*, is used for similar purposes, but has the following composition: Powdered gum-acacia 15 parts; powdered liquorice-root 10 parts; powdered sugar 5 parts. It is a yellowish-white powder, having the odor of liquorice-root and a sweet, mucilaginous taste.

Medical Uses.—This association of demulcents is hardly worthy of an official rank. It forms a dense mucilage used to suspend heavy powders, such as subnitrate of bismuth, etc.

PYRETHRUM, U. S.—PELLITORY.

Pyrethri radix, Br.; *Radix pyrethri romani*.—Pellitory-root, Pellitory of Spain, E.; *Pyrethre*, Salivaire, Fr.; *Römische Bertramwurzel*, G.

The root of *Anacyclus* (*Anthemis*, *Linne*) *Pyrethrum*, *De Candolle*. Woodville, t. 20; Bentley and Trimen, *Med. Plants*, 151.

Nat. Ord.—Compositæ, Anthemideæ.

Origin.—The pellitory is a procumbent or ascending perennial which is indigenous to North-western Africa and is occasionally cultivated in gardens. It resembles the chamomile, but has broadly oval, three-toothed, white ray-florets tinged with red beneath, and compressed obovate akenes, which have a short denticulate pappus; those of the outer rows have also a narrow wing. The root is shipped from Algiers and Tunis to Italy and France, and large quantities are sent to India by way of Egypt.

Description.—Pellitory-root is nearly simple, 2 to 4 inches (5–10 Cm.) long, $\frac{1}{4}$ to $\frac{1}{2}$ inch (6–12 Mm.) thick, somewhat fusiform, and occasionally beset with a tuft of the hairy base of stem and leaves, annulate above, deeply wrinkled below, of a grayish or blackish-brown color externally and brownish-white internally. It breaks with a short fracture, and presents a bark about one-eighth the thickness of the root, and a radiated medullium containing slender ligneous and medullary rays. The bark contains about two, and the medullary rays four or six, irregular circles of shining resin-cells. The root is inodorous, and has an aromatic and acrid taste, exciting a prickling sensation in the lips and tongue and a glowing heat.

Constituents.—Pellitory-root was analyzed by John, Gautier (1823), Parisel (1832), and Koene (1835); its acidity appears to reside in a brown resin and in two fixed oils, one having a dark-brown, the other a yellow, color. Buchheim (1876) asserts that the active principle is an alkaloid, *pyrethrine*, which under the influence of alcoholic solution of potassa yields *pyrethric acid*, resembling piperic acid. The root contains considerable inulin, a trace of tannin, mucilaginous matter, and other common constituents. Parisel's pyrethrin was a mixture of resin and fat.

Pharmaceutical Preparations.—PILULÆ ODONTALGICÆ, Toothache pills. Beat together in a warm mortar powdered pellitory, belladonna-root, and opium, each 5 Gm.; yellow wax 7 Gm.; expressed oil of almond 2 Gm.; oil of cajuput and oil of cloves, each 15 drops. Divide the mass into pills each weighing 0.05 Gm., and dust them with powdered cloves.—P. G., 1872.

Off. Prep.—Tinctura pyrethri, Br.

Allied Plants.—RADIX PYRETHRI GERMANICI.—German pellitory, E.; *Pyrethre allemande*, Fr.; *Bertramwurzel*, G.—This is obtained from *Anacyclus officinarum*, Hayne (Bentley and Trimen, 152), which is not known in the wild state, but has been long cultivated near Magdeburg and in Saxony; some botanists regard it as an annual form of the above species. It is an erect annual, resembling the preceding species in foliage and flowers, but the latter have a very convex disk. The root is from 4 to 6 inches (10–15 Cm.) long, about $\frac{1}{4}$ inch (3 Mm.) thick, has few rootlets, is externally brown-gray and internally dingy white. The bark is rather thick, and contains one irregular circle of rather large resin-cells; the medullium consists of slender brownish wood-wedges and whitish medullary rays, which are free from resin-cells. The root is inodorous and agrees in taste with the preceding.

PYRETHRUM (CHRYSANTHEMUM) ROSEUM and P. CARNEUM, *Bieberstein*.—Persian Pellitory, Persian insect-flowers, E.; *Camomille de Perse*, Fr.; *Persische Bertramblumen*, G.—Both plants are hardy perennials, resembling chamomile in appearance, and indigenous to Western Asia from Persia to the Caucasus Mountains. The flowers are the parts employed, and are used in the form of powder for killing insects. The flower-heads are about $1\frac{1}{2}$ inches (38 Mm.) broad, and have an imbricate involucre, with a brown scarious margin, a convex naked and solid receptacle, about twenty-four ray-florets, and a large number of yellow disk-florets. The ray-florets are ligulate, nerved and three-toothed, the disk-florets tubular and five-toothed. The akenes are dark-brown, angular, not winged, and crowned with a short membranous pappus. *Pyrethrum roseum* has rose-colored ray-florets and anthers included in the tube of the corolla. *Pyr. carneum* has purplish ray-florets, and anthers projecting with their appendages from the floret-tube. The flowers have a peculiar not very strong odor and an acrid taste. The flowers of *Pyr. cinerariæfolium*, *Trerivannus*, of Dalmatia, possess similar properties. Hanaman and Koch (1863) ascribed the insecti-

FIG. 231.

Transverse sections, magnified three diameters, of the roots of—*a*, *Anacyclus pyrethrum*, D. C.; *b*, *Anacyclus officinarum*, Hayne.

cide effects of the flowers to the volatile oil. Rother (1876) announced the isolation from insect-flowers of an oleoresinous acid, *persicin*, another acid resinous substance, *persiretin*, and a readily soluble glucoside, *persicin*, yielding persiretin when boiled with acids. He ascribes the effects of the flowers to persicin. Semenoff (1876) claimed to have obtained from them a volatile substance, which is probably an alkaloid, and Jousset de Bellesme (1876) regarded a crystalline *alkaloid* as the active principle. Oscar Textor (1881) found neither volatile oil nor alkaloid; he attributes the poisonous action to a soft resin, which is readily extracted by benzol, is soluble in alcohol and in potassa, is reprecipitated by an acid, and mixes readily with strong sulphuric acid, but is reprecipitated by a little water. Dal Sie (1879) believes a volatile crystallizable acid to be the active principle of Dalmatian insect-powder.

The *quality* of insect powder, according to Kalbrunner (1874), is best ascertained by sprinkling 4 grains of it upon a fly contained in a vial, which should be stupefied in 1 minute and killed in 2 or 3 minutes. Experiments demonstrating the fatal action upon insects of Persian pellitory have been published by Carpenter (*Am. Jour. Phar.*, May, 1879, p. 246).

Medical Action and Uses.—Pellitory is a powerful irritant, and acts as a rubefacient upon the skin. When chewed it has an acrid taste, and excites a burning and prickling sensation in the mouth and fauces and a copious flow of saliva. A child three and a half years old one evening swallowed about 50 minims of tincture of pyrethrum. During the night no symptoms occurred except soreness of the tongue, restlessness, and profuse perspiration. At five o'clock the next morning diarrhœa commenced with pain, and at eleven the child lay in a semi-stupor, the pupils natural, the pulse 120 and feeble; twitching of the muscles of the limbs, the tongue swollen and of a drab color; no vomiting, but profuse diarrhœa with tenesmus, and involuntary evacuations of bloody mucus. At 12.30 violent convulsions followed by profound stupor; at three o'clock and later tetanoid spasms and mental excitement with incessant talking. The next morning the intestinal disorder and the spasms had subsided, but the pulse continued frequent for 2 days. Laudanum, wine, and coffee were administered, and ice was applied to the forehead and spine (Browné). Its sialagogue properties have caused it to be used for the relief of *pains about the face and head*. Boiled in vinegar and applied to carious cavities in teeth, it is used to relieve *toothache*. In *paralysis* of the tongue or pharynx and in relaxation of the *urula* it may be employed as a masticatory or in a gargle. Its powder has been recommended as a sternutatory in chronic inflammation of the *frontal sinuses*. Its *dose* as a masticatory is from 30 to 60 grains (Gm. 2-4).

PYROXYLINUM, U. S.—PYROXYLIN.

Pyroxylin, Br.; *Lana collodii*.—*Soluble gun-cotton*, *Collodion cotton*, E.; *Fulmicoton soluble*, Fr.; *Collodiumwolle*, G.

Preparation.—Cotton 1 part (1 oz. av.); Nitric Acid 10 parts (10 oz. av. or 6½ fluidounces); Sulphuric Acid 12 parts (12 oz. av. or 6½ fluidounces); Alcohol, Stronger Ether, Water, each a sufficient quantity. Mix the acids gradually in a glass or porcelain vessel, and when the temperature of the mixture has fallen to 32° C. (90° F.) add the cotton. By means of a glass rod imbue it thoroughly with the acids, and allow it to macerate for 10 hours, or until a small sample of the cotton, taken out, thoroughly washed with a large quantity of water and subsequently with alcohol, and pressed, is found to be soluble when shaken in a test-tube with a mixture of 1 volume of alcohol and 3 volumes of stronger ether. Then remove the cotton from the acids, transfer it to a larger vessel, and wash it first with cold water until the washings cease to have an acid taste, and afterward with boiling water. Finally, drain the pyroxylin on filtering-paper and dry it in small, detached pellets by means of a water-bath. Pyroxylin should be kept loosely packed, in well-closed vessels containing not more than about 31 Gm. (or about 480 grains), in a cool and dry place remote from lights or fire.—U. S.

Take of cotton 1 ounce; sulphuric acid, nitric acid, each 5 fluidounces. Mix the acids in a porcelain mortar, immerse the cotton in the mixture, and stir it for 3 minutes with a glass rod until it is thoroughly wetted by the acids. Transfer the cotton to a vessel containing water, stir it well with a glass rod, decant the liquid, pour more water upon the mass, agitate again, and repeat the affusion, agitation, and decantation until the washing ceases to give a precipitate with chloride of barium. Drain the product on filtering-paper and dry in a water-bath.—Br.

The French Codex has a similar formula, but somewhat different proportions: it directs the maceration of 55 parts of well-dried cotton in a mixture of 1000 parts sulphuric acid specific gravity 1.84 and 500 parts nitric acid specific gravity 1.42, which

has been cooled to 30° C. (86° F.). The German Pharmacopœia directs a mixture of 1000 parts of crude sulphuric acid sp. gr. 1.830 and 400 parts of crude nitric acid sp. gr. 1.380; when cooled to 20° C. (68° F.), 55 parts of purified cotton are to be macerated in the mixture for 24 hours at a temperature of 15–20° C. (59°–68° F.).

A large number of formulas for preparing collodion cotton have been published, many with the nitric acid replaced by a nitrate, and the sulphuric acid correspondingly increased in quantity. Such mixtures may be made to yield as good results as the mixture of the two acids, but, owing to the separation of crystalline sulphates, it is more difficult to imbue the cotton thoroughly and uniformly with the mixture. Mann (1853) found the following proportions serviceable for 1 part of cotton: 20 parts potassium nitrate and 31 parts sulphuric acid specific gravity 1.830 to 1.835, or 10 parts potassium nitrate and 33 parts sulphuric acid specific gravity 1.80; the mixture is cooled to 30° C. (86° F.), and the cotton macerated at the same temperature for not less than 1 day or more than 6 days. Good results will also be obtained with a mixture of 17 parts sodium nitrate and 68 parts sulphuric acid specific gravity 1.78, or of 34 parts sodium nitrate and 66 parts sulphuric acid specific gravity 1.80; the cotton is introduced after 24 hours and macerated for 5 days. Klie (1877) succeeded with proportions nearly identical with those of Mann's first formula.

In making collodion cotton it is essential that due attention be paid to the strength of the acids, or, if a nitrate is used, to its freedom from chloride; likewise, that the temperature be permitted to fall as indicated before the cotton, which should be free from fat, is introduced, and that the cotton be thoroughly imbued with the acid mixture. If introduced at too high a temperature other insoluble nitro-compounds will be produced or the cotton will dissolve, and portions not moistened with the liquid will not be acted on, and likewise remain insoluble. Small portions of the cotton may from time to time be examined, thoroughly washed with water, afterward with alcohol, pressed, and then examined as to their solubility in a mixture of ether and alcohol. When these are found to be soluble, the cotton is withdrawn or the whole mixture added to a large bulk of water, the cotton washed with water until free from acid taste, then pressed to free it from water, steeped in alcohol, and again pressed, after which it may be dried by exposure at a moderate temperature (25° C. *P. G.*). The yield is usually about 140 per cent.

Properties and Composition.—Pelouze (1838) obtained explosive nitro-compounds by treating cotton, hemp, and paper with strong nitric acid. In 1846, Schoenbein announced the discovery of *gun-cotton*, and in the same year Otto published a process for preparing it by maceration in fuming nitric acid. In 1848, Maynard employed *collodion*. That *gun-cotton* is a nitrated substitution-compound of cellulose was recognized at an early day, and that the weight of the product is greater than that of the cotton employed. Regarding cellulose as the triatomic alcohol $C_6H_7O_2(OH)_3$, three nitric ethers of it may be prepared—namely, *pyroxylin* or *gun-cotton*, $C_6H_7O_2(NO_3)_3$, which is violently explosive and is insoluble in ether; *collodion cotton* or *colloxylin*, $C_6H_7O_2(OH)(NO_3)_2$, which is soluble in ether; and $C_6H_7O_2(OH)_2(NO_3)$, which is insoluble in ether. Hadow (1855) distinguished (1) *pyroxylin*, $C_{18}H_{21}(NO_2)_9O_{15}$; (2) the compound $C_{18}H_{22}(NO_2)_8O_{15}$; and (3) $C_{18}H_{23}(NO_2)_7O_{15}$, of which the latter was called by Gladstone *cotton xyloidin*, and has also been named *colloxylin*. The first weighs about 81 per cent. more than the cotton, is highly explosive, insoluble in ether and alcoholic ether, but soluble in acetic ether. The second shows an increase in weight of about 71 per cent., is soluble in ether-alcohol, but insoluble in glacial acetic acid. The third shows an increase of about 64 per cent., and is soluble in ether and glacial acetic acid, and is the variety aimed at in the preparation of collodion. Usually two, or occasionally all three, compounds are obtained at the same time. The cotton is apparently not altered in structure or appearance, and when these nitrated compounds are digested with sulphhydrate of potassium they are again converted into cotton.

Similar nitrated compounds are also obtained from other carbohydrates; thus starch yields with concentrated nitric acid a transparent jelly of *xyloidin*, $C_6H_9(NO_2)_3O_5$, and a similar change is produced in paper by dipping it into strong nitric acid and afterward washing with water.

Preservation.—When collodion cotton, particularly in the moist state, is kept in well-stopped bottles, it undergoes decomposition, frequently accompanied with the evolution of nitrous vapors or with ignition and explosion. It is best preserved in a dry atmosphere and enclosed in vessels which permit the free access of air.

Off. Prep.—Collodium, *U. S., Br.*

Medical Uses.—This article is not used medicinally.

QUASSIA, U. S.—QUASSIA.

Quassia lignum, Br.; *Lignum quassia*, P. G.—*Quassia-wood*, *Bitter-wood*, *Bitter ash*, E.; *Quassie*, *Bois amer*, Fr.; *Quassienholz*, *Fliegenholz*, G.

The wood of *Pierana excelsa*, Lindley, s. *Quassia* (*Simaruba*, De Candolle, *Pierasma*, Planchon) *excelsa*, Swartz. Steph. and Church, *Med. Bot.*, t. 173; Bentley and Trimen, *Med. Plants*, 57.

Nat. Ord.—Simarubaceæ.

Origin.—This is a large tree common in the island of Jamaica and in some other West Indian islands. It attains a height of 60 to 80 feet (18–24 M.) and a diameter of 2 to 3 feet (.6–.9 M.) and in aspect resembles the common ash. It has imparipinnate leaves, with short-stalked oval-lanceolate entire leaflets, and dense cymes of small white polygamous flowers, followed by black subglobular drupes of the size of a pea.

Description.—Jamaica quassia-wood is imported in billets varying in length from 3 to 6 feet (.9–1.8 M.) and in thickness from a few to 10 or 20 inches (25–50 Cm.). It is usually deprived of the bark, is dense, tough, of medium hardness, yellowish-white in color, splitting lengthwise coarsely splintery, and is frequently marked with irregular black lines or patches, due to the mycelium of a fungus. On a transverse section are seen a minute central pith, numerous narrow medullary rays composed of two or three rows of cells, wood-tissue containing large vessels, and irregular wavy concentric circles resembling annual rings. The wood is inodorous and has an intensely and purely bitter taste. In the shops it is usually found in raspings or chips, and the wood is turned into cups which are sold as *bitter cups* or *quassia cups*.

Constituents.—Winckler (1835) isolated the bitter principle *quassiin* or *quassin* from the concentrated decoction by precipitating pectin with lime, evaporating the filtrate, exhausting the residue with alcohol, mixing with ether, filtering, and evaporating spontaneously. A. Christensen (1882) prepared it by neutralizing the infusion of quassia with soda, precipitating with tannin, and decomposing the precipitate with lead oxide or lime. Quassin has the composition $(C_{31}H_{42}O_9)$ (Christensen)—according to Wiggers (1837), $C_{10}H_{12}O_3$. It crystallizes in thin rectangular plates, in small prisms, or in silky needles of a very bitter taste, is easily soluble in hot alcohol and in chloroform, sparingly soluble in ether and benzin, and dissolves slowly in cold water. Acids, alkalies, and certain salts increase the solubility of quassin in water. By treatment with warm diluted sulphuric acid it is converted into a resin and a compound which has the formula $C_{31}H_{42}O_9$, reduces silver nitrate, and is not precipitated by tannin. The yield of quassin is .05 to .15 per cent.

Allied Drugs.—SURINAM QUASSIA, which is used on the continent of Europe, is the wood of *Quassia amara*, Linné, a large shrub or small tree indigenous to Surinam. It is met with in commerce in billets about 1 to 4 inches (2–10 Cm.) in diameter or in pieces not thicker than a finger; it has very fine, almost obscure, one-rowed medullary rays and smaller vessels, and is therefore apparently less porous; otherwise, it closely resembles the preceding. The German Pharmacopœia permits the use of this and the preceding variety of quassia.

QUASSIA-BARK OF SURINAM is about $\frac{1}{3}$ to $\frac{1}{2}$ inch (.8–2 Mm.) thick, very fragile, externally of a gray color and nearly smooth, internally whitish and smooth.

QUASSIA-BARK OF JAMAICA varies from about $\frac{1}{4}$ to $\frac{1}{2}$ inch (4–8 Mm.) in thickness, is externally blackish-gray, longitudinally furrowed and verrucose, and on the inner surface yellowish-white and smooth. When broken transversely the fracture is smooth in the outer and tough and fibrous in the inner layer; the latter portion is seen to be radially striate. Both quassia-barks are easily removed from the wood, with the bitter taste of which they agree.

Off. Prep.—Extract. quassiaë fluid., U. S.; Extract quassiaë, Tinet. quassiaë, U. S.; Br.; Infus. quassiaë, Br.

Physiological Action.—Quassia is fatal to flies, and is sometimes used to preserve botanical collections from the ravages of insects. Rabbits and dogs have been killed by a concentrated preparation of the drug, the latter even by its application to the raw skin, and when its effects were not fatal it produced a partial paralysis of the limbs. Its bitter taste is more intense than that of most other stomachic tonics; like them, it excites the appetite for food and quickens digestion, but if too long continued it produces derangement of the stomach. Quassia may exhibit poisonous qualities, as in the following case: A concentrated infusion of the drug was by mistake given in enema to a child four years old. Within an hour the child became unconscious and collapsed, the head was thrown back and the pupils were contracted, the respiration was inaudible, and the pulse could not be felt. It was restored by alcohol, ether, and ammonia (*Med. Record*,

xviii. 404). The following conclusions were reached by Campardon in regard to quassin, crystallized and amorphous (*Bull de théér.*, ciii. 385): In moderate doses it increases the secretion of the saliva, the bile, the urine, and perhaps of the milk. It stimulates the excretory ducts of the several organs producing these secretions. In appropriate cases of sickness it quickens the appetite, renews the strength, facilitates the excretions, renders defecation easier, and hastens the expulsion of renal and biliary calculi. Its toxic action resembles that of the convulsing poisons. $2\frac{1}{2}$ grains (Gm. 0.15) of amorphous, or $\frac{1}{4}$ grain (Gm. 0.015) of crystallized quassin will occasion the following symptoms: a burning in the throat and œsophagus and a sense of constriction in the former; frontal headache; epigastric weight and pain; nausea, vertigo; confused vision, extreme restlessness, and feverish impatience; unsteadiness of mind; frequent urination, loose stools, and vomiting; cramps and spasms in the muscles of the lower limbs.

Medical Uses.—In debilitated states of the digestion quassia enjoys a merited reputation, especially in *dyspepsia* with regurgitation or vomiting of the food, produced by an exhausted condition of the stomach and accompanied more or less frequently with sick headache. Especially is it of use in *gastric vertigo* when associated with bicarbonate of sodium. In atonic *diarrhœa* due to irritation of the colon by accumulated feces the medicine is also beneficial. Quassia was once held to be a remedy for *lumbricoid worms*, which it is, partly because it improves the digestive powers. Enemas of infusion of quassia are efficient remedies for *ascarides* of the rectum.

The dose of the powder is stated at 20 or 30 grains (Gm. 1.30–2), but it is seldom administered in this manner. The most appropriate form of the medicine is the infusion made with cold water. Quasin is best administered in pill made with the amorphous preparation and containing from $\frac{1}{4}$ to 1 gr. (Gm. 0.025–0.06). Crystallized quassin is given in doses of $\frac{1}{30}$ to $\frac{1}{10}$ grain (Gm. 0.002–0.006). Campardon prefers the former, and states that the medicine does not occasion tolerance, and that its characteristic action is sometimes seen for a month after its disuse in salivation, increased flow of urine, and regularity of the stools.

QUEBRACHO.—QUEBRACHO.

Quebracho, E., Fr., G.

The bark of *Aspidosperma Quebracho*, *Schlechtendal*.

Nat. Ord.—Apocynaceæ.

Origin.—The term *quebracho* (*quebrar hacho*) signifies “breaking the axe,” and is applied in South America to trees having a very hard wood. The above species is called *quebracho blanco*, on account of its light-colored wood. It is a large evergreen tree, having thin drooping branchlets. The leaves are small, opposite, or in whorls of three, nearly sessile, elliptic-lanceolate, sharply pointed, and with an entire and callous margin; the small yellow flowers are in axillary cymes, and produce woody somewhat compressed capsules with broadly-winged seeds. The plant was discovered by Burmeister (1860); specimens of the bark were sent to Europe by Schickedanz (1878), and chemically examined by Fraude and Hesse. A thorough histological examination of the bark was made by A. Hansen (1880). The bark is collected from old trees after the corky layer has been well developed; though it contains only 3.48 per cent. of tannin, according to Paschkins, it is used in the Argentine Republic to some extent for tanning.

Description.—Quebracho-bark is seen in flattish or curved pieces varying in size and having a thickness of $\frac{1}{2}$ to $1\frac{1}{2}$ inches (12–30 Mm.). The outer surface is deeply fissured and warty, dingy ochre-colored or pale-brownish, or, after abrasion of this layer, brownish-red or of a bright orange-brown color; the inner surface is usually deep-brown, but occasionally pale-colored. The bark is nearly inodorous, has a bitter and slightly aromatic taste, and breaks in the outer layer with a short granular, and in the inner layer with a fibrous, fracture. Upon transverse section about one-half or more of the bark is seen to consist of an irregular corky layer, orange-brown in the interior, marked with irregular tangential lines of alternating suberous bands and parenchyma, and in the latter with numerous whitish dots formed by groups of stone-cells. The inner bark forms a brown (or yellowish) layer nearly uniform in thickness, having narrow medullary rays, numerous whitish dots of stone-cells in groups, and scattered bast-fibres, each being almost completely enveloped in a sheath of small crystal-cells.

Constituents.—Schickedanz isolated a crystalline alkaloid, which Fraude named *aspidospermine*; Hesse found in addition five other alkaloids, one of which (*quebracha-*

mine) appears to be sometimes wanting. The extract, prepared with hot alcohol, is treated with soda and chloroform, the latter solution evaporated, the residue taken up with diluted sulphuric acid, and the filtrate precipitated by soda. On dissolving the mixed alkaloids in a little boiling alcohol, aspidospermine, quebrachine, and quebrachamine will crystallize on cooling, and are separated by crystallization from diluted hydrochloric acid, aspidospermine remaining in the mother-liquor. The alcoholic mother-liquor contains the remaining three bases, which are combined with acetic acid; from this solution ammonia precipitates aspidosamine; aspidospermatine and hypoquebrachine are precipitated by soda and separated by boiling benzin, in which the latter is nearly insoluble. All these alkaloids are more or less soluble in alcohol, ether, and chloroform. *Aspidospermine*, $C_{22}H_{30}N_2O_2$, melts at 205°C . (401°F .), and is a weak base, forming mostly amorphous salts; warm perchloric acid colors the solution permanently deep-red; platinum chloride gives a blue precipitate; sulphuric acid and lead peroxide (or potassium bichromate) color the alkaloid brown, afterward cherry-red or purplish. *Aspidospermatine*, $C_{22}H_{28}N_2O_2$, melts at 162°C . (324°F .), is a strong base, and yields amorphous salts; it is colored, like the preceding, by perchloric acid, but not by sulphuric acid and chromate. *Aspidosamine*, $C_{22}H_{28}N_2O_2$, melts near 100°C . (212°F .), is a strong base, is colored blue by sulphuric acid and chromate, and gives with boiling perchloric acid a fuchsine-red liquid. *Quebrachine*, $C_{21}H_{26}N_2O_3$, melts at 215°C . (419°F .), yields crystallizable salts, is colored yellow by sunlight, also by warming with perchloric acid, and gives with sulphuric acid a colorless solution becoming blue on standing or more rapidly by lead peroxide or potassium chromate, the color produced by the latter changing to red-brown. *Quebrachamine* resembles the preceding, but melts at 142°C . (288°F .), and is freely soluble in cold alcohol and ether. *Hypoquebrachine* is yellow, amorphous, melts near 80°C . (176°F .), and gives in solution a cherry-red color with ferric chloride.

Tests.—For recognizing quebracho-bark *Fraude* recommends the following: Boil 5 Gm. of the bruised bark with 25 Gm. of benzin; filter while hot, agitate the liquid with 10 Ccm. of diluted sulphuric acid, separate the aqueous solution, supersaturate with ammonia, agitate with ether, evaporate the ethereal solution, and boil the residue with perchloric acid; or, dissolve it in a little water with 4 drops of sulphuric acid, add a minute crystal of potassium chlorate, and boil; the solution should acquire a fuchsine-red color.

Pharmaceutical Preparations.—**TINCTURA QUEBRACHO.** Quebracho-bark 1 part; diluted alcohol sufficient for obtaining 5 parts of tincture.

VINUM QUEBRACHO. Quebracho-bark 1 part; diluted alcohol 2 parts; white wine sufficient for obtaining 15 parts of liquid.

Allied Drugs.—**LOXOPTERYGIUM LORENTZII**, *Grisebach* (nat. ord. Terebinthaceae, Anacardiaceae). This tree is known in the Argentine Republic as *quebracho colorado*, the wood of which is red-brown and contains about 20 per cent. of tannin. Hansen (1880) describes the bark as being externally dingy-yellow or brown, usually covered with lichens; the transverse section is light-brown, and shows numerous parallel dark-colored corky bands, which are traversed at right angles by many fine light-colored medullary rays; between the latter are regular tangential rows of groups of stone-cells, imparting to the tissue a checkered appearance; the bast-fibres are the same as in white quebracho-bark, surrounded by a sheath of crystal-cells, but they are always much smaller, and are arranged in nearly rectangular groups. Hesse considers its tannin to be very similar to that of catechu, and has obtained two bitter alkaloids: *loxopterygine* is very soluble in alcohol, ether, and chloroform, and is colored blood-red by nitric acid; the second alkaloid is very easily decomposed, and yields with diluted sulphuric acid a beautiful blue solution. The resinous exudation of the bark resembles kino in appearance and taste, and, according to Arate (1878), is soluble in alcohol, amylie alcohol, acetone, acetic ether, acetic acid, and hot water.

IODINA RHOMBIFOLIA, *Hooker et Arnott* (nat. ord. Aquifoliaceae), is known as *quebracho flajo*, and **MACHLERIUM FERTILE**, *Grisebach* (nat. ord. Leguminosae), as *tipa*. The wood and bark of both species are used like the preceding, and occasionally collected with it.

COPALCHI-BARK (see page 396) has been sold as quebracho.

(See also *paytine*, page 465, and *GEISSOSPERMUM*, page 1034.)

Physiological Action.—The experiments of Penzoldt led him to formulate distinctly the conclusion that the action of quebracho is upon the blood alone: in medicinal doses, he said, it enables the blood to take up more than its normal proportion of oxygen and convey it to the tissues; and in poisonous doses it probably enables the blood to retain that oxygen in itself, and not yield it to the tissues, so that dyspnoea from a deficiency of oxygen in the medulla ensues (*Die Wirkungen der Quebrachdrogen*, 1881, pp. 23, 25). Gutmann, on the other hand (*Die Aspidosperminpräparate*, *Archiv f.*

exper. Pathol. u. Pharm., 1881, xiv. 451), concluded that aspidospermin is both a respiratory and a cardiac poison; that in cold-blooded animals it paralyzes respiration and destroys life by its action on the "noeud vital;" that respiration paralysis is accompanied with sedation of the heart "from paralysis of the automatic heart-ganglia of the sympathetic," the temperature declining and the dyspnoea increasing; that it causes death by heart paralysis and venosity of the blood, without previous convulsions; and that while in frogs death is preceded by paralysis of the voluntary muscles, no such paralysis can with certainty be observed in warm-blooded animals. The antagonism of these two theories is apparently absolute. *Non nobis tantas componere lites.* As in other cases of such dissidence, we are obliged to turn to clinical observation, not to explain the action of the drug, but, for the only purpose that concerns practical physicians, to justify its use as a medicine.

Medical Uses.—In 1879, Penzoldt described quebracho as a medicine that without any injurious collateral effects promptly diminishes or removes sundry forms of dyspnoea in various diseases of the respiratory and circulatory apparatus. He observed a reduction of the respiration-rate under its influence, without any corresponding lowering of the pulse-rate. It seemed to produce a sense of warmth in the head, but neither vertigo nor somnolence. Sometimes it excited diaphoresis, sometimes also salivation, and in some cases of pulmonary disease the cough and expectoration grew less. Penzoldt saw no bad consequences from its use, but other physicians have noted its disagreeable taste and the nausea it is apt to cause. According to Laquer, if the use of the medicine is prolonged it is apt to occasion headache, dulness of the senses, vertigo, and salivation, and the patients acquire an extreme disgust for it (*Bull. de therap.*, xeviii. 379). Picot assures us that it enabled him to ascend a mountain without shortness of breath—a feat which he could not otherwise accomplish (*Bull. de therap.*, xeviii. 379).

Penzoldt states that of all diseases *asthma* with emphysema is most benefited by it, and that it did not fail of its effect even when pleurisy or bronchitis was also present. In *phthisis*, *bronchial asthma*, and diseases of the heart its palliative action was marked, and was also evident in a case of pulmonary embolism; but when the heart-muscle was weak the influence of the medicine was not salutary, nor indeed in any case in which the condition of the heart was the primary cause of the dyspnoea. In this respect it is no substitute for digitalis. In a case of uræmic asthma it was very efficient. In opposition to one of these statements, Berthold reports two cases of fatty degeneration of the heart in which the dyspnoea was greatly relieved by the medicine (*Bull. de therap.*, xeviii. 379), but it is probable that the dyspnoea arose from some other cause added to the degeneration of the heart-tissue. In a word, the medicine appears to be a palliative for the symptom dyspnoea; the degree and the duration of the relief which it affords will in each case depend upon the nature and the degree of the physical cause of that symptom. In this country we have the statement that Dr. Austin Flint tried quebracho in several cases of dyspnoea from phthisis and pneumonia without avail, but that in an extreme case of dyspnoea from mitral regurgitation it was very efficacious (*Med. News*, May, 1881, p. 273). Dr. Andrew H. Smith has reported the results of his use of the medicine in thirty-two cases of various diseases, including eleven of *spasmodic asthma*. Of the latter, nine cases were relieved, and of the total number of cases, including diseases of the lungs, heart, and kidneys, twenty-two were benefited more or less (*Med. Record*, xx. 559). Quite a similar result is reported by Gottheil (*Ibid.*, xxiv. 259), by Mariasi (*Bull. de thé.*, cv. 311), by Da Costa (*Boston Med. and Surg. Jour.*, Dec. 1883, p. 620), and by Maragliano (*Centralblatt f. d. g. Therapie*, ii. 63). It is difficult to assign to the medicine its precise clinical value, but the general impression conveyed by a study of its effects is, that the more nearly the symptom dyspnoea is independent of an organic cause the better will be the influence of the medicine upon it.

The preparation recommended by Penzoldt is as follows: Take 10 parts of the powdered bark; treat for several days with 100 parts of alcohol; evaporate the latter, and dissolve the extract in 20 parts of warm water. *Dose*, 1 or 2 teaspoonfuls three times a day. The solution, he says, is of a clear sherry color, has a slightly astringent and aromatic taste, and is not hard to take. Maragliano states that quebrachin and aspidospermin act in about half an hour by the mouth, and in from 5 to 10 minutes hypodermically. For the latter purpose he employed the sulphate in doses of 1 or 2 grains (Gm. 0.05–0.10), and a solution of 1 grain in 15 grains of water caused neither local nor general disturbance.

QUERCUS ALBA, U. S.—WHITE OAK.

Cortex quercus.—Oak-bark, E.; *Écorce de chêne*, Fr.; *Eichenrinde*, G.

The bark of *Quercus alba*, *Linne* (U. S.), *Q. Robur*, *Linne* (Br., P. G.). Bentley and Trimen, *Med. Plants*, 248, 250, 251.

Nat. Ord.—Cupuliferæ.

Origin.—The oaks are shrubs or trees growing chiefly in the temperate zone, and often forming extensive forests. They have monoecious flowers, the staminate ones in slender and naked catkins, and the pistillate flowers either single or in small groups, and followed by a one-seeded nut, the *acorn*, which is enclosed at the base by a *cup* formed by the indurated scaly involucre. The leaves of some species are entire or nearly so, but most species have sinuately toothed or lobed or even pinnatifid leaves, which are coriaceous and evergreen or mostly deciduous.

The white oak is a stately tree, 60 to 80 feet (18–24 M.) high and 6 to 8 feet (1.8–2.4 M.) thick. It grows from Canada to Northern Florida, and west to Wisconsin and Eastern Texas. The wood is light-colored, strong, and durable; the leaves are sinuately-lobed, smooth, and on the lower side pale glaucous; the cup is saucer-shaped, tuberculate, and much shorter than the oblong acorn.

The European oak, which somewhat resembles the white oak, grows to the height of 100 or 120 feet (30 or 40 M.). Three varieties are known, which are regarded by some botanists as distinct species; in the variety *pubescens* the old leaves remain hairy, in *sessiflora* they are smooth, and both have the pistillate flowers and fruit sessile, while in the variety *pedunculata* they are raised upon a long peduncle. The European pharmacopœias usually direct the bark to be collected from the branches or young stems.

Description.—The bark is collected early in spring, and is deprived of the greater portion of the longitudinally fissured thick suberous layer. It is in nearly flat pieces, about $\frac{1}{4}$ inch (6 Mm.) or more thick, of a pale-brown color externally, with occasional patches of the gray scaly cork: the inner surface is somewhat lighter in color, and marked with sharp longitudinal ridges, produced by the bast-bundles projecting from the shrunken parenchyma. The bark is tough, breaks with a coarse fibrous fracture, and has a faint tan-like odor and a strongly astringent taste. It is kept in the shops in the form of an irregular coarse and fibrous powder, which scarcely tinges the saliva. The tissue contains groups of stone-cells and crystals of calcium oxalate.

Oak-bark as used in Europe is in quills, the bark being about $\frac{1}{2}$ inch (2 Mm.) thick; the outer surface is gray or brown-gray, glossy, and smooth or somewhat fissured; the inner surface is cinnamon-colored and somewhat ridged. The bark breaks with a smooth, and in the inner layer with a fibrous, fracture, and in odor and taste resembles the preceding.

Constituents.—The important constituent of oak-bark is tannin; gallic acid does not appear to be present. The tannin produces with ferric salts a dark blue-black precipitate, but it is not identical with gallotannic acid, since, according to Stenhouse (1842), it is incapable of being converted either into gallic or pyrogallie acid. This *quercitanic acid* is yellowish-brown, amorphous, yields a brown precipitate with acetate of lead, and was found by Stenhouse (1862) to yield sugar when boiled with dilute sulphuric acid. But, according to J. Löwe (1881), this tannin is not a glucoside; it is separated anhydrous, $C_{28}H_{24}O_{12}$, by saturating its solution with sodium chloride; it is almost insoluble in ether, but dissolves readily in acetic ether; it gives yellowish-white precipitates with gelatin, albumen, tartar emetic, and the alkaloids, and when heated with dilute acids under pressure yields *oak-red*, $C_{28}H_{22}O_{11}$. The infusion of oak-bark yields to ether a little gallic and ellagic acids. It is not known whether the tannins of the different oak-barks are alike. Bowman (1869) determined the amount of tannin in young white-oak bark, by means of gelatin, to be 11.21 per cent., and in the bark from older trunks only 6.34 per cent. Gerber (1843) obtained from the bark of the European oak a bitter principle which may also be present in the bark of other species. A decoction of the bark of older branches with very dilute sulphuric acid is mixed with lime, precipitated with potassium carbonate, evaporated, and extracted with alcohol, on the evaporation of which *quercin* remains behind in white bitter crystals.

Other Products of Oak. (See also GALLÉ, pp. 721, 722.)

QUERCUS TINCTORIA, *Bartram* (s. *Q. velutina*, *Lamarek*). This is the *black oak*, the bark of which was formerly official, and is largely employed in the arts under the name of *quercitron-bark*. The tree grows from Canada and the New England States to Alabama and beyond the Mississippi. It is 80 to 100 feet (24–30 M.) high, and has a close-grained and strong wood. The

leaves are somewhat pubescent on the lower surface and bristle-pointed on the lobes; the cup is coarsely scaly, hemispherical, conical at the base, and covers fully one-half of the globular-ovate acorn. Gray regards it as a variety of *Qu. coccinea*, *Wangenheim*, the *scarlet oak*. The bark resembles that of the white oak, but the suberous layer, which is generally removed, is of a blackish-brown color, and the inner bark of a deep reddish-brown with a yellowish tint. Like the preceding, it is usually kept as a coarse powder; when masticated it tinges the saliva bright brownish-yellow, due to the presence of *quercitrin*, which has been met with in many plants. This is deposited from the decoction of black-oak bark on cooling, forms when pure a yellow crystalline, inodorous, and nearly tasteless powder, which is sparingly soluble in hot and nearly insoluble in cold water, dissolves in about 5 parts of alcohol, slightly in ether, is colored dark-green by ferric chloride, and dissolved in alkalies becomes dark-brown on exposure. Its formula is $C_{35}H_{30}O_{17}$ ($C_{36}H_{38}O_{20}$, Liebermann, 1879). Treated with acids, it splits into the crystalline unfermentable sugar *isodulcit*, $C_6H_{14}O_6$, and into *quercetin*, $C_{27}H_{18}O_{12}$ ($C_{24}H_{16}O_{11}$, Liebermann); the latter is likewise yellow and crystalline, is found ready formed in a number of plants, is colored dark-green by ferric chloride, precipitated brick-red by acetate of lead, sublimable, by alkalies resolved into phloroglucin and *quercetic acid*, $C_{15}H_{10}O_7$, and with fusing potassa yields protocatechuic acid.

QUERCUS FALCATA, Michaux, s. *Q. elongata*, Willdenow. This is the *Spanish oak* of the Southern and Middle United States. It grows to the height of 70 feet (21 M.), has a reddish coarse-grained wood, and yields a thick bark rich in tannin.

QUERCUS NIGRA, Linné, s. *Q. ferruginea*, Michaux, is the *black jack* of the Middle and Southern States; it is a small tree, growing in barren soil, and is of little value.

QUERCUS VIRENS, Aiton, the *live-oak*, is about 50 feet (15 M.) high, and has a yellowish, very compact, and fine-grained valuable wood, and a bark rich in tannin. The live-oaks of the Pacific coast are *Quercus chrysolepis*, Liebm., *Q. agrifolia*, Née, and *Q. oblongifolia*, Torrey, the latter occurring principally in Southern California.

QUERCUS SUBER, Linné, the *cork-oak*, grows in the basin of the Mediterranean, and has been introduced into the Southern United States. It grows 40 to 50 feet (12–15 M.) high; has evergreen elliptic or ovate mostly sharp-toothed leaves, and produces an elastic suberous layer $1\frac{1}{4}$ to 2 inches (3–5 cm.) thick, which is collected every eight or ten years and constitutes the cork of commerce. Kütler (1884) obtained from air-dry cork about .6 per cent. of ash rich in manganese, a little coniferin, about 5 per cent. of tannin and derivatives, and about 12 per cent. of chloroformic extract, including the crystallizable *cerin*, $C_{20}H_{32}O$; the fat *suberin* cannot be extracted by simple solvents, but is saponified by potassa, yielding glycerin and stearic and *phellonic acids*, the latter having the composition $C_{22}H_{42}O_3$. Finely-powdered cork has been employed as an absorbent dusting powder under the name of *suberin*.

SEMIN QUERCUS TOSTUM. Acorns are roasted in the same manner as coffee until they have acquired a brown color, when they are coarsely powdered. This is used as *acorn coffee* (Eichelkaffee, *G.*). According to Braconnot's analysis (1849), acorns contain starch, fixed oil, citric acid, uncrystallizable sugar, and another sugar which Dessaigne (1851) named *quercit*, $C_6H_{12}O_5$.

Off. Prep.—Decoctum quercus, *Br.*

Medical Action and Uses.—In ancient times oak-bark was used in the treatment of *hemoptysis* and *dysentery*, and pessaries made of the bruised bark were employed to restrain *uterine hemorrhage*. The crushed leaves were applied to strengthen relaxed parts. In modern times it has been resorted to for the same purposes, and also to cure *bronchial flux*. It has been maintained that persons who work in tan-pits are never attacked with *intermittent fever*, and that they enjoy a like immunity from *phthisis*. Externally, the decoction, which is officinal, has been applied to all the purposes of vegetable astringents; indeed, oak-bark is rarely used except in the form of decoction. Cases are reported in which vaginal injections of a decoction of oak-bark were followed by symptoms of peritonitis (*Boston Med. and Surg. Jour.*, Oct. 1879, p. 523). *Suberin*, above referred to, is used as a dressing for *chapped nipples* and similar lesions in the same manner as lycopodium, to which it is preferable on account of its astringency. In many parts of England grated acorns are in common use by the rustic population as a medicine for diarrhœa. This custom, which is a survival of ancient medicine, also prevails in various parts of France. Roasted acorns are likewise used for this purpose, as well as in the treatment of flatulent dyspepsia and of scrofula.

QUILLAIA, U. S.—QUILLAIA-BARK.

Soap-bark, E.; *Écorce de quillaya*, Fr.; *Seifenrinde*, G.

The inner bark of *Quillaia Saponaria*, Molina.

Nat. Ord.—Rosaceæ, Roseæ.

Origin.—The tree yielding quillaia-bark is indigenous to Peru and Chili, and has evergreen, leathery, entire leaves, and small umbels of four diœcious flowers, producing five many-seeded capsules.

Description.—The bark comes in flat pieces, sometimes 2 or 3 feet (60–90 Cm.) long, several inches wide, and about $\frac{1}{4}$ inch (6 Mm.) thick. The thick brown corky layer is usually removed, small patches of it merely adhering to the outer surface, which is otherwise nearly smooth and pale-brownish white, like the inner surface. The bark is hard and tough, breaks with a splintery fracture, and shows upon transverse section a checkered appearance, due to the tangential arrangement of the light-brown bast-fibres and white bast-parenchyma, and to the white narrow radial lines of the medullary rays. The bark has no odor, but its dust is acrid and sternutatory; it has a persistent acrid taste and its infusion foams like a solution of soap.

Constituents.—Quillaia-bark contains numerous minute crystals of sulphate of calcium, a small quantity of starch, and considerable *saponin*. The latter principle was isolated from quillaia-bark by Le Bœuff (1850), and may be obtained by displacing the powder with hot alcohol and allowing the tincture to cool. The cold tincture retains some saponin in solution, together with resinous and oily matters, and, when evaporated and agitated with water yields a permanent emulsion. In its pure state saponin is a white amorphous powder which causes sneezing, is nearly inodorous, has a sweetish afterward acrid taste, is soluble in 4 parts of water, more soluble in weak than in strong alcohol, and insoluble in ether and volatile oils. Its aqueous solution is precipitated by baryta-water, the precipitate being soluble in pure water, but not in baryta-water (Rochleder). It has the composition $(C_{32}H_{54}O_{18})_n$, and when treated with acids yields a saccharine body and a series of decomposition-products, the final one being *sapogenin*, $C_{14}H_{22}O_{11}$, a sparingly soluble, white crystalline compound. (See also SAPONARIA.)

Pharmaceutical Uses.—TINCTURE QUILLAIÆ is made by exhausting 1 part of the bark with sufficient alcohol to obtain 5 parts of tincture. 1 part of it will emulsify from 1 to 3 parts of volatile oil or oleoresin and 8 or 10 parts of fixed oil.

EXTRACTUM QUILLAIÆ, also called *quillain*. Prepared with hot water, S. A. McDonnell obtained 20 to 25 per cent. of a brown not hygroscopic extract, of which 1 grain dissolved in 1 oz. of water will yield a tolerably permanent emulsion with 1 oz. of fixed oil or 1 drachm of oleoresin.

Medical Action and Uses.—Soap-bark owes its name and the property of causing water in which it is macerated to froth to the presence of saponin. Whether it possesses any of the virtues of other plants containing this principle (*senega*, *saponaria*) does not clearly appear. It has, however, been used with alleged advantage in *dropsy* and in chronic *bronchitis*, and is reported to be a sternutatory and useful in *coryza*, and also as a febrifuge. It may be administered in an infusion made with an ounce of the bark and a pint of water (Gm. 32 in Gm. 500), to be taken during a day. The dry aqueous extract dissolves readily in water, and such a solution may be employed for making emulsions of castor, cod-liver, and other oils. The external uses of the bark appear to be the most important. It may be used instead of soap for washing the hairy scalp and other parts of the skin affected with *eruptions*, *ulcers*, etc., for removing the greasy coating which some skins exude, and for correcting the fetor which the feet, armpits, etc. in other persons exhale. For the latter purposes a saturated tincture may be added to water until it acquires the proper saponaceous quality. The tincture has also been used to promote the renewal of the hair in alopecia (*Phila. Med. Times*, xi. 29).

QUINIDINÆ SULPHAS, U. S.—SULPHATE OF QUINIDINE.

Chinidinum (Conchininum) sulfuricum.—Sulphate of conquinine, E.; Sulfate de quinine, Fr.; Schwefelsaures Chinidin, Conchininsulfat, G.

Formula $(C_{20}H_{24}N_2O_2)H_2SO_4 \cdot 2H_2O$. Molecular weight 782.

Preparation.—The mother-liquors from the recrystallization of sulphate of quinine yield on concentration a crop of crystals consisting chiefly of this salt, which is purified by treatment with animal charcoal and by recrystallizing it. On adding to the mother-liquors a considerable excess of ammonia, cinchonine will be precipitated and quinidine dissolved; the solution deposits the alkaloid quinidine, together with impurities, on the addition of soda. The alkaloid may then be dissolved in dilute sulphuric acid, and the salt purified by recrystallization. Since quinidine enters the mother-liquors containing the amorphous alkaloids, and is precipitated with chinoidine, it may be prepared from the latter, according to Hesse (1868), by exhausting it with ether, converting the dissolved alkaloids into sulphates, precipitating quinine and cinchonidine with Rochelle salt, purifying the filtrate with animal charcoal, and precipitating the quinidine with potassium iodide;

the alkaloid is then liberated by ammonia, combined with sulphuric acid, and the salt crystallized.

Properties.—Sulphate of quinidine (or of *conquinine*, according to Hesse) crystallizes in white, silky needles which resemble those of the quinine salt, but are less matted and do not effloresce on exposure even when heated to 80° C. (176° F.); when heated to 120° C. (248° F.) they part with their water of crystallization (4.6 per cent.). The solution in dilute sulphuric acid shows the blue fluorescence of quinine solutions and strikes an emerald-green color on the successive addition of chlorine-water and ammonia, and a red color on the successive addition of chlorine-water, potassium ferrocyanide, and ammonia. The salt has also, like the corresponding quinine salt, a very bitter taste and a neutral reaction. It dissolves at 10° C. (50° F.) in 108 parts (Hesse), at 15° C. (59° F.) in 98 parts (Kerner), and at the boiling-point in 7 parts of water; also in 8 parts of alcohol at 15° C. (U. S.), and when anhydrous in 105 parts of chloroform. The salt is freely soluble in hot alcohol, but is nearly insoluble in ether. The chloroform solution on evaporation leaves the salt in an amorphous state, and on exposure to diffused daylight gradually acquires a green color, but the alkaloid is not perceptibly affected thereby (Hesse, 1879). The aqueous solution yields with barium chloride a white precipitate which is insoluble in hydrochloric acid; with ammonia, a white precipitate, soluble in a large excess of ammonia and in thirty times its weight of ether; with potassium ferrocyanide, golden-yellow prisms or a yellow crystalline precipitate; and with potassium iodide from neutral solution, a white, and from acid solution a reddish-yellow, crystalline precipitate. When a drop of the solution is mixed with a drop of solution of potassium sulphocyanide, the microscope reveals groups of radiating feathery crystals; this sulphocyanide of quinidine requires 1477 parts of water for solution. (For the characteristics of the alkaloid see page 466).

Quinidine sulphate with KSCy:
microscopic crystals.

Tests.—When heated on platinum-foil the salt should burn without leaving any residue. Neither sulphuric nor nitric acid should impart any color to the dry salt. De Vrij (1878) advises testing this salt as follows: 1 Gm. of it is dissolved in 50 Gm. of hot water, and 0.5 Gm. potassium iodide added; a sandy crystalline precipitate must fall, and after some hours the mother-liquor, on being tested with ammonia, should not produce an appreciable precipitate. This test has been formulated as follows: "If 0.5 Gm. each of sulphate of quinidine and of iodide of potassium (not alkaline to test-paper) be agitated with 10 Ccm. of water at about 60 C. (140° F.), the mixture then macerated at 15 C. (59° F.) for half an hour, with frequent stirring, and filtered, the addition to the filtrate of a drop or two of water of ammonia should not cause more than a slight turbidity (absence of more than small proportions of cinchonine, cinchonidine, or quinine)." — U. S.

Allied Salts.—QUINIDINÆ BISULPHAS, Acid sulphate of quinidine, $C_{20}H_{24}N_2O_2 \cdot H_2SO_4 \cdot 4H_2O$; mol. weight 494. It is obtained by dissolving the sulphate in sufficient diluted sulphuric acid, and evaporating. It forms long colorless prisms of an asbestos-like appearance, soluble in 8.7 parts of water at 10° C. (50° F.) and losing 14.57 per cent. of water at 120° C. (248° F.).

QUINIDINÆ HYDRIODAS, $C_{20}H_{24}N_2O_2 \cdot HI$. It is obtained by double decomposition of neutral solutions of quinidine sulphate and potassium iodide as a white crystalline powder, or from warm and somewhat diluted solutions in colorless scaly prisms. It is slightly soluble in alcohol and in hot water, and requires at 10° C. (50° F.) 1270 parts, and at 15° C. (59° F.) 1250 parts, of water for solution. The salt is anhydrous and contains 28.09 per cent. of iodine.

QUINIDINÆ BIHYDRIODAS, $C_{20}H_{24}N_2O_2 \cdot (HI)_2 \cdot 3H_2O$. It is prepared like the preceding salt, using, however, a warm acidulated solution of quinidine sulphate. It forms an orange-colored crystalline powder or glossy golden-yellow prisms, turns brown-yellow at 120° C. (248° F.) from loss of water, which is absorbed again on exposure to moist air, and is soluble in 90 parts of cold water, and more freely soluble in alcohol and in hot water. The salt contains 8.5 per cent. of water and 43.77 per cent. of iodine.

Medical Action and Uses.—As an anti-periodic in *malarial affections*, and as an anti-pyretic in *fever* generally, sulphate of quinidine is equal to sulphate of quinine, and may be used in similar doses. It has been thought less apt to disagree with the stomach and to cause unpleasant nervous symptoms (Peacock); on the other hand, "the greatest

drawback to its use, especially with typhoid patients, is the subsequent vomiting which often occurs" (Strümpell, *Practitioner*, xxiii. 128).

QUININA, U. S.—QUININE.

Chinimum.—*Quinine*, Fr.; *Chinin*, G.

Formula $C_{20}H_{24}N_2O_2 \cdot 3H_2O$. Molecular weight 378.

An alkaloid prepared from different species of *Cinchona* and *Remijia*.

Preparation.—On precipitating a solution of quinine sulphate in acidulated water with an alkali, a curdy, amorphous, white precipitate is obtained, consisting of the anhydrous alkaloid, which if kept under the liquid is gradually changed to the crystalline hydrate of the above formula. It requires to be washed with distilled water and dried at a low temperature. The same hydrate may also be obtained from the solution of the alkaloid in diluted alcohol by crystallizing at a low temperature, while at 30° C. (86° F.) silky needles of anhydrous quinine are separated (Hesse). On concentrating a solution of quinine in ammonia-water the hydrate crystallizes. The precipitation of quinine should be effected without heat, and only a slight excess of ammonia should be used to prevent loss of the alkaloid.

Properties.—Hydrate of quinine forms long, colorless, silky needles, or more frequently a white crystalline powder; the Pharmacopœia describes it also as flaky and amorphous. In dry air the crystals become opaque, and when kept over sulphuric acid it readily parts with $2H_2O$ (9.5 per cent.), but very slowly with the remaining 4.8 per cent. of water of crystallization. The alkaloid, like its salts, is inodorous, and has a persistently bitter taste, which, owing to its sparing solubility, is slowly developed. The powder and its solutions in water and alcohol have an alkaline reaction. The hydrate melts at a temperature of 57° C. (134.6° F.); on continuing and slowly increasing the heat it loses its water of crystallization, then becomes solid, melts again at 176° C. (347.4° F.), and at a higher heat burns slowly, without leaving any residue. Anhydrous quinine requires at 15° C. (59° F.) 1960 parts of water for solution, but the hydrate dissolves at 15° C. in 1670 parts (Hesse), at 20° C. (68° F.) in 1428 parts, and at the boiling-point in 773 parts, of water (Sestini); these solutions on being evaporated between 60° and 80° C. (140° and 176° F.) separate the hydrate in the form of oily drops. According to Regnaud, quinine is soluble at 15° C. (59° F.) in 1.134 parts of absolute alcohol, in 1.93 parts of chloroform, and in 22.63 parts (16 to 25.5 parts, Hesse) of ether. It is soluble in 6 parts of alcohol, in about 200 parts of glycerin, and in 2 parts of boiling alcohol (*U. S. P.*); dissolves freely in carbon disulphide, more sparingly in fixed and volatile oils; also in benzin and in benzol; the latter solution leaves on spontaneous evaporation a crystalline compound of quinine and benzol, which is decomposed at a moderate heat. The solutions turn polarized light to the left.

Quinine is a strong base, neutralizes the strongest acids, forming crystallizable salts which, if soluble, have an intensely bitter taste, and displaces ammonia from its salts on being heated with their solutions. The acidulated solutions show a vivid blue fluorescence, which disappears on the addition of hydrochloric, hydriodic, and sulphocyanic acids and of hyposulphites. On passing chlorine gas into water containing quinine in suspension, the liquid acquires a reddish color, changing to violet and dark-red, and then becomes lighter, with the separation of a red compound (Pelletier). But if the acid solution is mixed first with sufficient chlorine-water (or bromine-water), and then with an excess of ammonia, the solution becomes emerald-green from the production of *thalleioquin* or *thalleiochin* (Brandes), the color being observable in a solution containing $\frac{1}{5000}$ part of quinine; on carefully neutralizing the liquid the color changes to blue, and with an excess of acid to purplish or red; the addition of an excess of ammonia restores the green color. If to the quinine solution be added chlorine-water, then potassium ferrocyanide, and finally ammonia, a deep-red color is produced.

Quinine heated with glycerin to about 190° C. (374° F.) is converted into the isomeric base *quinicine*, which was discovered by Pasteur (1853), and may be obtained from most acid quinine salts by heating them to about 130° C. (266° F.); the salts of this base are readily crystallizable, are colored green by chlorine-water and ammonia, and yield with hypochlorites white precipitates which are turned green by ammonia.

Tests.—For the detection of other cinchona alkaloids the Pharmacopœia has adopted Kerner's test. (See QUININÆ SULPHAS.) "Quinine should afford no color, or none darker than a pale-yellow, with undiluted sulphuric acid (absence of foreign organic matters), nor should it be reddened by nitric acid (difference from morphine). If 1 Gm

of quinine be mixed in a mortar with 0.5 Gm. of sulphate of ammonium and 5 Cem. of distilled water, the mixture thoroughly dried on the water-bath, the residue (which should be neutral to test-paper) agitated with 10 Cem. of distilled water, this mixture macerated at 15° C. (59° F.) for half an hour, then filtered through a small filter, 5 Cem. of the filtrate taken in a test-tube, and 7 Cem. of water of ammonia (sp. gr. 0.960) then added, on closing the test-tube with the finger and gently turning it until the ammonia is fully intermixed, a clear liquid should be obtained. If the temperature of maceration has been 16° C. (60.8 F.), 7.5 Cem. of the water of ammonia may be added; if 17° C. (62.6° F.), 8 Cem. may be added. In each instance a clear liquid indicates the absence of more than about 1 per cent. of cinchonidine and quinidine, and of more than traces of cinchonine."—*U. S.*

Off. Prep.—Ferri et quininæ citras, Liqueur Ferri et quininæ citratis, Syrupus ferri, Quininæ et strychninæ phosphatum, *U. S.*

QUININÆ BISULPHAS, *U. S.*—BISULPHATE OF QUININE.

Chininum bisulfuricum, P. G.; *Quininæ sulphas acidus*.—*Acid sulphate of quinine*, E.; *Sulfate acide (Bisulfate) de quinine*, Fr.; *Saures Chininsulfat*, *Chininbisulfat*, G.

Formula $C_{20}H_{24}N_2O_2 \cdot H_2SO_4 \cdot 7H_2O$. Molecular weight 548.

Preparation.—Mix 100 grains of ordinary quinine sulphate with about 500 grains (9 fluidrachms) of warm distilled water; add to the mixture 115 grains of official diluted sulphuric acid; filter if necessary, and set aside in a moderately warm place to crystallize; dry the crystals over sulphuric acid at a temperature of 10° or 15° C. (50°–59° F.), and preserve them in a well-stopped bottle in a cool and dark place. The yield is 125 grains.

A solution of the salt may be prepared extemporaneously by dissolving 8 grains of quinine sulphate in water with the aid of 9 minims (or 9½ grains) of diluted sulphuric acid; the solution will contain 10 grains of the acid sulphate of quinine.

Properties.—The salt crystallizes in colorless rhombic prisms or plates, or it forms small needles which on exposure to light become yellowish, are free from odor, and have a strong bitter taste and a decided acid reaction. At 25° C. (77° F.) it loses water, the crystals becoming opaque; but the last molecule of water is not expelled until heated to about 100° C. (212° F.). The salt fuses in a glass tube at 80° C. (176° F.) (*P. G.*), but heated in the air it melts near 135° C. (275° F.), and is converted into acid *quinicine sulphate*, which is easily soluble in alcohol and water, and crystallizes in long yellow prisms. According to Hesse (1873), acid sulphate of quinine dissolves at 13° C. (55.4° F.) in 11 parts, and at 22° C. (71.6° F.) in 8 parts, of water, but it requires more alcohol (32 parts *U. S.*, *P. G.*) for solution, and is very soluble in both liquids heated to boiling. The solutions have a decided blue fluorescence, which may be observed in water containing $\frac{1}{1000000}$ part of the salt. The aqueous solution becomes emerald-green on the addition of chlorine-water and ammonia, and behaves to ammonia-water and barium chloride like sulphate of quinine, giving white precipitates with both reagents, of which the former is easily soluble in excess of ammonia and in ether, and the latter is insoluble in hydrochloric acid.

This pharmacopœial salt should not be confounded with the true *bisulphate of quinine*, $C_{20}H_{24}N_2O_2(H_2SO_4)_2 \cdot 7H_2O$, which is obtained from 100 grains of quinine sulphate and 350 grains of diluted sulphuric acid, the solution being crystallized over sulphuric acid. It contains 19.5 per cent. of water, readily acquires a brown-red color on exposure to light, is easily soluble in water with a strong blue fluorescence, and separates from boiling alcohol on cooling as a gelatinous mass, which on drying forms minute prisms.

Tests.—The salt should not be (or at most but very slightly, *U. S.*) colored by sulphuric acid (absence of sugar, salicin, etc.), nor by nitric acid (morphine, brucine, etc.). 1 Gm. of the salt dried at 100° C. should leave a residue weighing 0.77 Gm. (absence of water and of other quinine sulphates, the latter leaving 80 and 85 per cent. of residue).—*U. S.*, *P. G.* The aqueous solution should not be precipitated by silver nitrate (absence of hydrochlorate). The absence of an excess of other cinchona alkaloids is determined by Kerner's test, as follows: "If 1 Gm. of the salt, previously dried at 100° C. (212° F.), be agitated with 8 Cem. of distilled water, the mixture made exactly neutral to test-paper by the cautious addition of water of ammonia, then increased by the addition of distilled water to 10 Cem., and macerated at 15° C. (59° F.) for half an hour, upon proceeding further, as directed for the corresponding test under quinine (see QUININA), the results given for the latter should be obtained."—*U. S.* Or, "an intimate mixture of 1 Gm. of

the salt and of 0.5 Gm. of ammonia-water is well dried in a water-bath, the residue treated with 10 Cem. of distilled water and further tested with ammonia-water, as directed for Kerner's test."—*P. G.*

Medical Action and Uses.—When sulphate of quinine is given in solution, it is generally converted into the bisulphate by the addition of aromatic sulphuric acid. The dose of the two salts is practically the same.

QUININÆ HYDROBROMAS, *U. S.*—HYDROBROMATE OF QUININE.

Chininum hydrobromicum, s. hydrobromatum.—*Bromhydrate de quinine, Fr.; Chininhydrobromat, G.*

Formula $C_{20}H_{24}N_2O_2HBr \cdot 2H_2O$. Molecular weight 440.9.

Preparation.—This salt is prepared by double decomposition of quinine sulphate with barium bromide. A mixture of 100 grains of quinine sulphate and 1400 grains (3 fluidounces) of water is heated to boiling, and gradually mixed with a solution of 34 grains of barium bromide in 225 grains ($\frac{1}{2}$ fluidounce) of water; the precipitate is allowed to settle, and the clear hot liquid is tested for barium salt with a cold solution of quinine sulphate prepared without the aid of additional acid, and if free from barium is filtered and evaporated to crystallize. The yield is about 100 grains. Owing to the insolubility of barium chloride and the ready solubility of barium bromide in absolute alcohol, Boille (1874) recommends dissolving both the barium and the quinine salts in strong alcohol; the solutions are then mixed, taking care that the quinine sulphate is in slight excess; after filtering water is added, the alcohol distilled off, the liquid cooled, filtered from any quinine sulphate which may crystallize out, and evaporated to crystallize. If the salt be not quite white it should be recrystallized from water.

The salt may also be prepared by dissolving quinine in warm diluted hydrobromic acid until the acid reaction has completely disappeared. Or, according to Hager, 100 parts of quinine sulphate and 27.5 parts of potassium bromide are well triturated with 100 parts of water; the mixture is moderately heated, mixed with 400 parts of alcohol, the whole digested for an hour, filtered while warm from the precipitated potassium sulphate, and crystallized. Leger's process (1880) is similar to this.

Properties.—Quinine hydrobromate is in colorless, lustrous needles, permanent in ordinary air, but readily efflorescing with a gentle heat, odorless, having a very bitter taste and a neutral or slightly alkaline reaction; soluble in about 16 parts of water and in 3 parts of alcohol at 15° C. (59° F.), in 1 part of boiling water, and in less than 1 part of boiling alcohol, in 6 parts of ether, in 12 parts of chloroform, and moderately soluble in glycerin. On ignition the salt burns slowly without leaving a residue. The aqueous solution, when acidulated with sulphuric acid, has a blue fluorescence, and when treated first with fresh chlorine-water and then with a slight excess of water of ammonia, it produces an emerald-green color. Water of ammonia added to the aqueous solution throws down a white precipitate easily soluble in an excess of water of ammonia, as well as in ether. Test solution of nitrate of silver produces a white precipitate which is insoluble in diluted nitric acid, and when filtered off and washed insoluble in solution of carbonate of ammonium. The aqueous solution, unless very much diluted, is precipitated by solutions of (neutral) sulphates."—*U. S.*

Composition.—The *U. S. Pharmacopœia* has adopted the formula of Hager, which requires 8.19 water, 18.10 bromine, and 73.49 per cent. of quinine. Boille (1874), however, found of these constituents respectively 4.80, 18.26, and 75.20 per cent., which closely corresponds with the formula $C_{20}H_{24}N_2O_2HBr \cdot H_2O$.

Tests.—The salt should not be colored, or at most but very slightly colored, by undiluted sulphuric acid (absence of foreign organic matters), nor be reddened by nitric acid (difference from morphine). If a small portion of the salt be dried on the water-bath until it ceases to lose weight, and the residue cooled in a desiccator, the loss of weight should not exceed 8.2 per cent. The aqueous solution should not be rendered turbid by diluted sulphuric acid (absence of barium), and not more than slightly turbid by test solution of chloride of barium (limit of sulphate). If 1.5 Gm. of the salt be dissolved in 15 Cem. of hot distilled water, the solution stirred with 0.6 Gm. of crystallized sulphate of sodium in powder, the mixture maintained at 15° C. (59° F.) for half an hour, and then drained through a filter only large enough to contain it until 5 Cem. of filtrate are obtained, upon treating this liquid as directed for the corresponding test under quinine (see QUININA) the results given for the latter should be obtained."—*U. S.* The filtrate obtained in the last test is a solution of quinine sulphate saturated at 15° C.,

and should at the same temperature yield a clear liquid on being mixed with 7 Cem. of ammonia-water.

Allied Salts.—QUININÆ HYDROBROMAS ACIDUS, Acid hydrobromate of quinine, $C_{20}H_{24}N_2O_2 \cdot (HBr)_3 \cdot 3H_2O$. Quinine sulphate is dissolved in water with the aid of sufficient dilute sulphuric acid, completely precipitated with a solution of a barium bromide, avoiding an excess of the latter, the solution filtered from the barium sulphate, and evaporated to crystallize. This salt is soluble in 6 parts of water and is freely soluble in alcohol.

QUININÆ BROMAS, Bromate of quinine, $C_{20}H_{24}N_2O_2 \cdot HBrO_3$, is prepared by C. A. Cameron (1882) either by neutralizing quinine with bromic acid or by precipitating barium bromate with quinine sulphate. It forms asbestos-like masses consisting of long needles, dissolves in 250 parts of cold water, freely in warm water, in diluted acids, and in alcohol; it is not decomposed at a moderate heat, but detonates in contact with strong sulphuric acid.

Medical Action and Uses.—The official position of this salt is not justified by the small proportion of hydrobromic acid contained in an average dose of it. It was proposed by Gubler for hypodermic use on account of its solubility, its freedom from irritating qualities, and its richness in quinine. It does not appear, however, to have been extensively used. Its dose is about the same as that of the sulphate.

QUININÆ HYDROCHLORAS, U. S., Br.—HYDROBROMATE OF QUININE.

Chininum hydrochloricum, P. G.—*Muriate of quinine*, E.; *Chlorhydrate de quinine*, Fr.; *Chininhydrochlorat*, *Salzsaures Chinin*, G.

Formula $C_{20}H_{24}N_2O_2 \cdot HCl \cdot 2H_2O$. Molecular weight 396.4.

Preparation.—This salt is best obtained by dissolving quinine in warm diluted hydrochloric acid until the solution is neutral, and crystallizing. On a small scale it may be prepared by double decomposition. A solution of 100 grains of quinine sulphate in hot distilled water is precipitated by a solution of 28 grains of crystallized barium chloride or of 15 grains of anhydrous calcium chloride; the filtrate is tested with quinine sulphate, evaporated to dryness, redissolved in diluted alcohol to separate calcium sulphate, and evaporated to crystallize. Rother (1883) recommends for the same amount of sulphate $13\frac{1}{2}$ grains of sodium chloride and 350 grains ($7\frac{1}{2}$ fluidrachms) of alcohol; after sufficient digestion the filtrate is mixed with water and evaporated. The yield is 90 grains.

Properties.—Quinine hydrochlorate forms colorless needles, appearing white in mass, usually united to stellate groups, of a silky lustre, inodorous, and having a very bitter taste and a neutral (or faintly alkaline, U. S.) reaction. The salt is permanent in the air at low temperatures, but at a moderate heat effloresces, parting with a portion of its water, and at $100^\circ C.$ ($212^\circ F.$) loses all the water of crystallization, amounting to 9.08 per cent. The crystallized salt requires at $10^\circ C.$ ($50^\circ F.$) 35 parts of water (Hesse), at $15^\circ C.$ ($59^\circ F.$) 34 parts of water or 3 parts of alcohol (U. S. P. G.), for solution, and is very freely soluble in boiling water and in boiling alcohol. The anhydrous salt forms a permanent solution with 1 part of chloroform, and differs in this respect from the concentrated solutions of the hydrochlorates of cinchonine and cinchonidine, which after a short time become thick and crystalline, owing to the formation of more sparingly soluble compounds of the salts with the solvent (Hesse, 1873). The solution in alcohol or water is free from fluorescence, and the slight one appearing on dilution is removed by the addition of sulphuric or other acids. The hydrochlorate being much more soluble in water than sulphate of quinine, the latter salt is precipitated in needles on adding to a rather concentrated solution of the former a solution of a neutral sulphate. Quinine hydrochlorate on being exposed to the light gradually acquires a yellowish color, and should therefore be kept in a dark place. Its solution likewise becomes yellowish or brownish on keeping; with chlorine-water and ammonia it yields emerald-green thalleioquin; with ammonia a white precipitate is produced, soluble in an excess of ammonia and in ether; and with silver nitrate a white precipitate is obtained soluble in ammonia, but insoluble in nitric acid.

Tests.—The salt on being ignited upon platinum-foil should burn without leaving any residue (absence of inorganic matter). Heated with milk of lime or with dilute potassa solution, the odor of ammonia should not be given off (ammonium salts). Treated with strong sulphuric acid, the salt should at most be colored yellowish (absence of salicin, sugar, etc.). "With concentrated nitric acid it should not be colored red (morphine). 1 Gm. of the salt, heated in a water-bath to $100^\circ C.$ until it ceases to lose weight, should leave a residue weighing .91 Gm. (difference = water of crystallization). The solution

of the salt in (100 parts, *P. G.*) water should not become turbid by dilute sulphuric acid (absence of barium), nor more than slightly turbid with barium chloride (limit of sulphate).”—*U. S., P. G.* “If 2 Gm. of the salt, 1 Gm. of sodium sulphate, and 20 Gm. of water be evaporated to dryness, the residue boiled with 12 Gm. of alcohol, and the filtrate evaporated, the resulting quinine sulphate should respond to the tests for this salt.”—*P. G.* For the application of Kerner's test this process can be shortened as proposed by Hager and directed as follows: “If 1.5 Gm. be dissolved in 15 Cem. of hot distilled water, the solution stirred with 0.75 Gm. of crystallized sulphate of sodium in powder, the mixture maintained at 15° C. (59° F.) for half an hour, and then drained through a filter only large enough to contain it until 5 Cem. of filtrate are obtained, upon treating this liquid as directed for the corresponding test under quinine (see QUININA), the results given for the latter should be obtained.”—*U. S.*

Allied Salts.—QUININÆ HYDROCHLORAS ACIDUS, Acid hydrochlorate of quinine, is either amorphous or in white or yellowish crystalline masses, which are very soluble in water and readily darkened by light.

QUININÆ IODAS, Iodate of quinine, $C_{20}H_{24}N_2O_2 \cdot HI O_3$, according to C. A. Cameron (1882), is best prepared by digesting freshly-precipitated quinine in a molecule of iodic acid previously dissolved in 10 parts of warm water; the soft mass should be evaporated at 15.5° C. (60° F.) and dried over sulphuric acid. The salt is in minute white pearly needles, is readily soluble in alcohol, soluble in 700 parts of cold water, and is not decomposed by boiling water.

QUININÆ HYDRIODAS, Acid hydriodate of quinine, $C_{20}H_{24}N_2O_2 \cdot (HI)_2 \cdot 5H_2O$. This salt crystallizes from a warm acidulated solution of quinine on the addition of potassium iodide. It forms glossy transparent prisms or scales, becomes opaque at 30° C. (86° F.), melts at 100° C. (212° F.) in its water of crystallization, and becomes completely anhydrous at 120° C. (248° F.); when exposed to a damp atmosphere the anhydrous salt combines again with $2H_2O$ (Hesse, 1865).

Medical Action and Uses.—Hydrochlorate of quinine was early made officinal by the Dublin Pharmacopœia, and Neligan (1854) remarked of it, “It is preferred by many practitioners to the disulphate, but is much more expensive, and the dose is the same.” In 1855, Briquet, in his great work on *Cinchona*, said of it, “Being very liable to change by keeping, it cannot be depended upon, so that with good reason it is entirely disused.” In the same year Troussseau and Pidoux mentioned the muriate along with several other salts as being inferior to the sulphates. In 1857, Pereira's *Materia Medica* said of it only that “it is employed in the preparation of the valerianate of quinine.” In 1864, Guibert merely stated that “German physicians set great store by this medicine;” and one of the latest German writers, Bernatzik, says of it that its uses are those of the sulphate of quinine, but refers to its solubility and the relatively large proportion of quinine it contains. According to this authority, the dose should be one-sixth less than that of the sulphate, 100 parts by weight of muriate of quinine containing as much quinine as 121 parts of the sulphate. Binz refers to pure amorphous hydrochlorate of quinine as being especially adapted for subcutaneous injection, its advantages being not only that it is “very cheap,” but that it dissolves in an equal weight of water, and as a rule does not give rise to abscesses. Probably it was for use in hypodermic injections that the salt was made officinal. From 2 to 4 grains (Gm. 0.12–0.24) may be stated as the average dose administered in this manner.

QUININÆ SULPHAS, *U. S., Br.*—SULPHATE OF QUININE.

Quinise sulphas, *U. S.* 1870, *Br.*; *Chininum sulfuricum*, *P. G.*; *Sulfas quiniens*.—*Sulphate of quinia*, *E.*; *Sulfate de quinine*, *F.*; *Chininsulfat*, *Schwefelsaures Chinin*, *G.*

Formula $(C_{20}H_{24}N_2O_2)_2H_2SO_4 \cdot 7H_2O$. Molecular weight 872.

Preparation.—Take of Yellow Cinchona-Bark, in coarse powder, 1 pound; Hydrochloric Acid, 3 fluidounces; Distilled Water a sufficiency; Solution of Soda 4 pints; Diluted Sulphuric Acid a sufficiency. Dilute the hydrochloric acid with 10 pints of the water. Place the cinchona-bark in a porcelain basin, and add to it as much of the diluted hydrochloric acid as will render it thoroughly moist. After maceration with occasional stirring for 24 hours place the bark in a displacement apparatus, and percolate with the diluted hydrochloric acid until the solution which drops through is nearly destitute of bitter taste. Into this liquid pour the solution of soda, agitate well, let the precipitate completely subside, decant the supernatant fluid, collect the precipitate on a filter, and wash it with cold distilled water until the washings cease to have color. Transfer the precipitate to a porcelain dish containing a pint of distilled water, and, applying to this the heat of a water-bath, gradually add diluted sulphuric acid until very nearly the whole of the precipitate has been dissolved and a neutral liquid has been obtained.

Filter the solution while hot through paper, wash the filter with boiling distilled water, concentrate till a film forms on the surface of the solution, and set it aside to crystallize. The crystals should be dried on filtering-paper without the application of heat.—*Br.* 1867.

The preparation of sulphate of quinine from cinchona-bark involves the following processes: 1, extraction of the alkaloids in the form of a compound soluble in cold water; 2, precipitation of the alkaloids; and, 3, combination with sulphuric acid and separation of the various sulphates from one another and from coloring matter and other foreign principles. The alkaloids are easily extracted from the bark by water acidulated with hydrochloric or sulphuric acid, and are then in solution as hydrochlorates or sulphates. If an elevated temperature has been resorted to, derivatives of tannin and other principles will separate on cooling, and must either be filtered off or converted into insoluble compounds, which takes place on the addition of lime; this decomposes likewise the salts of the alkaloids, chloride or sulphate of calcium being formed, while the alkaloids are precipitated, together with the excess of lime employed, and the kinic acid remains in solution as kinate of calcium. The alkaloids are taken up from the lime precipitate by boiling alcohol, and left behind in an impure condition on the evaporation of the solvent. Soda cannot be profitably employed for precipitating the acid decoction unless it has been allowed to cool and filtered from the precipitate; or, still better, the bark is exhausted in the cold and the acid infusion rendered very slightly alkaline by caustic soda. The precipitate thus obtained will be less deeply colored than the residue left on the evaporation of the alcohol, as described before, and consists mainly of the mixed cinchona alkaloids. As obtained by one or the other process, the impure alkaloids are mixed with water, heat is applied, and sulphuric acid is dropped in, care being taken to leave a portion of the alkaloids and much coloring matter undissolved, which are removed by filtration; the hot filtrate may be treated with purified animal charcoal to remove remaining coloring matter, or even without this treatment will deposit crystals of the desired salt. If, however, sufficient sulphuric acid has been used to dissolve the whole of the impure alkaloids, the excess of the former has formed freely soluble sulphates, which would not crystallize on cooling. It is then necessary to remove not only coloring matter, but likewise the excess of sulphuric acid, which is accomplished by treatment with unpurified animal charcoal, the calcareous matter of which combines with the excess of the sulphuric acid, and on cooling the filtrate the same sulphate will crystallize that is obtained by the action of an insufficient quantity of the acid upon an excess of the impure alkaloids. The crystals of the first crop are neither sufficiently white nor free from other cinchona alkaloids, and require to be purified by three or four recrystallizations, when the sulphate of quinine, being the least soluble of the corresponding salts of the cinchona alkaloids, will crystallize first, leaving the coloring matter in the mother-liquor with the remaining alkaloids.

Numerous modifications of the processes described have been proposed, and are probably used by the manufacturers of cinchona alkaloids; and since it is often more economical, in the manufacture of quinine, not to use a costly bark rich in this alkaloid, but rather a cheaper one containing a smaller percentage of quinine, and in addition thereto a larger proportion of the other alkaloids, it is obvious that modifications of the processes will not unfrequently be found necessary. Of late years the so-called cuprea-bark (see page 462) has been extensively employed.

Instead of exhausting the bark with acidulated water, the natural combination of the alkaloids is sometimes broken up by a base, for which purpose ammonia, soda, and lime have been proposed. The two former remove tannin, kinic acid, cinchona-red, and other colored compounds, but at the same time dissolve a portion of quinine and the other alkaloids. By digesting the bark with lime-water some of the principles mentioned are dissolved, and the liquid may be utilized for preparing kinic acid; or milk of lime may be mixed with the powdered bark, and the mixture digested for some time, dried, and powdered. It contains then the calcium compounds of kinic acid, etc., which are nearly insoluble in strong alcohol and methylic and amylic alcohol, either of which solvents may be used in extracting the liberated alkaloids, which are then converted into sulphates and purified as stated above.

Most of the quinine consumed in the United States was formerly manufactured here; in the year 1876-77 the importation amounted to 75,804 ounces, and in 1883 to 1,055,764 ounces.

Properties.—Sulphate of quinine crystallizes in thin, snow-white, flexible, inodorous, monoclinic needles, which form a loose, voluminous, and easily compressible mass, and have a silky lustre or frequently are somewhat opaque in consequence of superficial efflorescence. The salt has a persistent and purely bitter taste, and does not affect moist litmus-paper. A drop of a concentrated solution evaporated on the slide of a microscope crystal-

lizes in stellate groups of thin needles or spikes. It effloresces rapidly on exposure, and when kept over sulphuric acid loses all except 2 molecules of water; the same loss occurs in dry air at a temperature of 25° to 30° C. (77° – 86° F.), and more rapidly at the summer temperature. The remaining water, amounting to 4.60 per cent. of the effloresced salt, is expelled at and above 100° C. (212° F.), and rapidly absorbed again in a damp atmosphere at ordinary temperatures. Quinine sulphate should be kept in well-stopped bottles, but when these are occasionally opened loss of water is unavoidable, and the salt becomes correspondingly richer in quinine. In the sunlight it acquires a yellowish color.

FIG. 233.

Quinine Sulphate: microscopic crystals.

At 160° C. (320° F.) it becomes phosphorescent on trituration, and at a red heat it is decomposed, and burns slowly without leaving any residue. It requires, according to Van Heijningen, 740 (according to Jobst and Hesse, 788) parts of water for solution at 10° C. (50° F.), and at the boiling temperature about 30 parts. The pharmacopœias state it to be soluble at 15° C. (59° F.) in 740 parts (U. S.), 800 parts (P. G.), of water and in 65 parts of alcohol (U. S.), and at the boiling temperature in about 30 parts (U. S.), in 25 parts (P. G.) of water, and in 3 parts (U. S.), in 6 parts (P. G.) of alcohol. It dissolves in 40 parts of glycerin, is insoluble in fixed oils, and is nearly insoluble in ether. When anhydrous it requires 1000 parts of chloroform for solution. Chloride of ammonium, nitrate of potassium, and some other salts increase its solubility in water, while it is less soluble in the presence of sodium sulphate

and magnesium sulphate or neutral tartrates. The solubility in water is very materially increased by most acids, owing to the formation of soluble acid salts. The solution in water is not fluorescent, but on the addition of sulphuric acid the characteristic blue fluorescence of quinine salts is observed. On adding to its solution an excess of chlorine-water, followed by ammonia, an emerald-green color is produced; and if, after chlorine-water, ferrocyanide of potassium is added, and then ammonia, the solution turns of a deep-red. (See QUININA.) Dissolved in distilled water, it yields white precipitates with nitrate or chloride of barium and with ammonia, the former precipitate being insoluble in hydrochloric acid, while the latter is easily soluble in an excess of the reagent and in about twenty times its weight of ether. It is likewise precipitated by potassa and soda, their carbonates and bicarbonates, by lime-water, tannin, and the other general reagents for alkaloids, and it is incompatible in solution with acetates, tartrates, and with liquids containing iodine (potassium iodide and ferric salts). Its solution in water or dilute acid remains unchanged when kept in the dark, but exposed to sunlight it turns yellowish and brown. Flückiger (1878) named this brown product *quinivetin*, and found it to be of the same composition as quinine, but destitute of alkaline reaction, and, though soluble in acids, it is not able to neutralize them, and is not precipitated by tannin; it has, however, a bitter and somewhat aromatic taste.

Composition.—The formula of crystallized sulphate of quinine has been given above; it is the one recognized by the pharmacopœias, and represents (in 100 parts) 74.31 anhydrous quinine, 11.24 sulphuric acid and 14.45 water. It is *diquinine sulphate*, but was formerly often described as *neutral* or *basic sulphate of quinine*. On drying the salt

FIG. 234.

Quinine Sulphate with KSCN: microscopic granules.

completely above 100° C. (212° F.) the residue, cooled in a desiccator, weighs theoretically 85.55 per cent., and is required to weigh not less than 85.6 (Br.), 85 (P. G.), 83.8 (U. S.) parts. The salt crystallizes from water with $8\text{H}_2\text{O}$ = 16.18 per cent., which is the water permitted by the U. S. P., although the formula with $7\text{H}_2\text{O}$ has been adopted as the correct one. But, according to Kerner (1880), 16 per cent. of water indicates superficially adhering moisture, and, according to Jobst and Hesse, the salt should contain at most $7\frac{1}{2}\text{H}_2\text{O}$, or 15.3 per cent. After complete efflorescence the formula is $(\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2)_2\text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$, and a salt of this composition will crystallize from alcohol in white permanent needles; it contains 82.87 per cent. quinine, 12.53 per cent. H_2SO_4 , and 4.6 per cent. water of crystallization.

Tests.—In examining the purity of sulphate of qui-

nine the following tests are of service: A drop of an aqueous solution of a quinine salt mixed with a drop of a solution of potassium sulphocyanide will at once become turbid, and under the microscope show a large number of minute globules, which even after a day are not aggregated into groups or crystals. According to Hesse (1878), sulphocyanide of quinine is insoluble in solution of potassium sulphocyanide, and more soluble in water than quinine sulphate; the microscopic test must therefore vary with the quantities used; he also observed that the minute globules are usually followed in a few minutes by many-rayed stellate groups of needles. The test proposed by Liebig depends upon the greater solubility of quinine in ether as compared with quinidine, cinchonine, and cinchonidine; modified by Hesse (1878), it is very delicate: 0.5 Gm. of quinine sulphate is well agitated with 10 Ccm. of water warmed to between 50° and 60° C. (122° and 140° F.); after 10 minutes the cooled liquid is filtered and 5 Ccm. of it are slowly agitated with 1 Ccm. (1 Gm., Rump) of ether and 5 drops of ammonia-water; after the separation of the ether both strata should be clear, even after the expiration of 2 hours. The Br. P. directs to recrystallize 100 gr. of the salt from 5 or 6 oz. boiling water with 3 or 4 drops diluted sulphuric acid. Use the mother-liquor for the test just described, and weigh any separated alkaloid, as *cinchonidine* or *cinchonine*. Shake the recrystallized salt with ether 1 fl. oz. and ammonia $\frac{1}{2}$ oz., and add ethereal liquid from preceding test; now shake with caustic soda (10 per cent.) solution 1 fl. oz., adding water if solid matter separates; wash with ether, heat aqueous liquid to boiling, neutralize exactly with sulphuric acid, and cool, when *cupreine sulphate* will crystallize, resulting from the decomposition of *homokinine* if present. *Quinidine* is separated as hydriodate from concentrated quinine solution by potassium iodide in the presence of a little alcohol.

Another test proposed by Hesse has been adopted by the German Pharmacopœia, as follows: 1 Gm. of quinine sulphate, on being warmed for a short time to between 40° and 50° C. (104° and 122° F.) with 7 Ccm. of a mixture composed of 2 volumes of chloroform and 1 volume of absolute alcohol, should yield a perfect solution, which should remain clear after cooling. Sulphates of other cinchona alkaloids and various organic and inorganic impurities are thus detected. The following is a similar but less delicate test: "20 Ccm. of absolute alcohol should dissolve 0.2 Gm. of the salt, forming a clear liquid."—*U. S.*

Kerner's test (1862), which depends upon the greater solubility of quinine in ammonia-water than the other cinchona alkaloids, is applied as follows: 2 Gm. of the salt are agitated, and then macerated for half an hour at 15° C. with 20 Ccm. of distilled water; of the filtered solution 5 Ccm. are introduced into a test-tube, and upon the surface of this liquid are carefully poured 7 Ccm. of ammonia-water sp. gr. .960; the test-tube is then closed with the finger and gently agitated, so as to mix the liquids, and the result should be a perfect solution free from any deposit. In order to succeed with this test it is necessary that the temperature and strength of ammonia solution should be strictly adhered to. Since 20 Gm. of water are unable to dissolve 2 Gm. of officinal sulphate of quinine, and since the sulphates of the other alkaloids are more freely soluble in water, it is obvious that the solution prepared as directed does not represent the quinine salt, but contains a much larger proportion of the other sulphates if they are present. Kerner required for 5 Ccm. of pure quinine sulphate 6.8 Ccm., of quinidine sulphate 78 Ccm., and of cinchonidine sulphate 81 Ccm. of ammonia-water sp. gr. .960, while 0.5 Ccm. of the solution of cinchonine sulphate remains turbid after the addition of 150 Ccm. of ammonia-water. A minute quantity of cinchonine present with the quinine sulphate may at first dissolve in the ammonia, but will separate in flakes on standing. This test has been adopted in the manner described by the German Pharmacopœia. The U. S. P. operates with one-half the quantity (1 Gm.) of the quinine salt, and directs it to be previously dried at 100° C.; for which there does not appear to be any necessity. It is macerated with 10 Ccm. of water, and further treated as just described. A valuable addition to the directions is the influence of temperature, as follows: "If the temperature of maceration has been 16° C. (60.8° F.), 7.5 Ccm. of the water of ammonia may be added; if 17° C. (62.6° F.), 8 Ccm. may be added; in each instance a clear liquid indicates the absence of more than about 1 per cent. of cinchonidine or quinidine, and of more than traces of cinchonine."—*U. S.* Kerner has recently (1881) modified his test as follows: The salt (2 Gm.) is well agitated with lukewarm water (20 Gm.); after about 1½ hours the liquid is cooled to exactly 15° C., filtered, and treated as before.

Hydrochlorate of cinchonine resembles sulphate of quinine in appearance, and has been occasionally substituted for it. It is easily detected by the aqueous solution yielding a curdy precipitate with nitrate of silver and a voluminous precipitate with ammonia, which is not dissolved by an excess of the precipitant or on being agitated with ether.

Other fraudulent admixtures or substitutions are recognized as follows: *Mineral impurities* by the fixed residue left on igniting a portion of the salt upon platinum-foil; *ammonia salts* by the ammoniacal odor given off on heating a portion of the salt with dilute potassa solution or milk of lime; *stearic acid, starch, cotton fibre*, and similar insoluble substances by their insolubility in dilute sulphuric acid; *gum* by its insolubility in alcohol; *salicin, phlorizin, sugar*, and other organic compounds by the red or brown color occasioned with warm concentrated sulphuric acid (a slight yellowish color is admissible for quinine); *morphine* as an accidental impurity by the red or orange color produced with strong nitric acid (several other alkaloids yield a similar color); *mannit* and other substances soluble in water by boiling a portion of the suspected salt with solution of baryta, passing carbonic acid gas into the mixture, and evaporating the filtrate; pure sulphate of quinine thus treated will leave only an insignificant residue.

According to the above-described tests, the purity of quinine sulphate is directed to be determined (1) by sulphuric acid (*U. S., Br., P. G.*); (2) by nitric acid (*U. S., P. G.*); (3) by absolute alcohol (*U. S.*); (4) by a mixture of chloroform and absolute alcohol (*P. G.*); (5) by milk of lime (*U. S.*); (6) by exsiccation (*U. S., Br., P. G.*); (7) by Kerner's test (*U. S., P. G.*); (8) by ether (*Br.*); (9) by potassium iodide (*Br.*).

"Sulphate of quinine should not contain much more than 5 per cent. of sulphates of other cinchona alkaloids."—*Br.*

Medical History.—A knowledge of the curative powers of Peruvian bark was not due to sagacious prescience or scientific investigations, but to the simple fact that in the early part of the seventeenth century the Spanish conquerors of Peru learned its virtues from the native Indians. Carried to Europe, learned bigotry condemned what unenlightened savages had discovered, and one religious body zealously spurned a priceless boon that had been introduced by another whose form of faith they derided. About the middle of the seventeenth century a large quantity of the bark was brought from America, and at a great council of the Jesuits at Rome was distributed to the members, who afterward carried it all over Europe; hence it was called Jesuits' bark. But it had still to encounter the sneers of the learned and the hate of bigotry, and it was not until an English quack succeeded in curing by its means men of high rank that fashion broke down the prejudices which reason could not remove. Thenceforth cinchona was everywhere applied to the cure of malarial fevers and fevers of a typhoid type, as well as to various other diseases.

The discovery of the active principles of cinchona, imperfectly made by Duncan in 1803, was perfected by Pelletier and Caventou in 1820, as far as regards quinine and cinchonine. Quinidine was discovered partially in 1833, but perfectly isolated in 1852. The introduction into practice of quinine and cinchonine dates from 1820–21.

Physiological Action.—The earlier experimenters with quinine upon the lower animals and upon man concluded that in small doses it acts as a stimulant of the nervous and circulatory systems, and in large doses as a direct sedative, producing general muscular and cardiac debility, and, when poisonous doses are given, great acceleration of the pulse, coma, and stertorous breathing. After death the lungs and brain were found engorged with blood. Later investigations have furnished minuter and more extensive information, according to which the action of quinine upon the economy may be described.

Small and frequently-repeated doses given to animals increase the *pulse-rate* even until death; at first they augment the force of the heart's contraction and then diminish it, although the rate of its movements progressively increases. Poisonous doses, especially when injected into the veins, annihilate the heart's contractility, producing rapid death, yet if the operation is not promptly fatal the respiratory movements cease before those of the heart. In such cases the blood-current is retarded, whether the observation be made in the first stage of action of the medicine, when the blood-vessels are contracted, or subsequently, when, under its prolonged influence, they have become dilated. The experiments, among others, of Cerna (*Phila. Med. Times*, x, 493) confirm these conclusions, and those of Panteljeff, showing the physiological antagonism of quinine and atropine, are to the same effect (*Practitioner*, xxv, 205). In the theoretical language of the day, the increased pulse-rate in the first or lower grade of action is due to stimulation of the excito-motor centre of the heart and paralysis of its regulating apparatus. According to some, the increase, and afterward the decline, in the heart's force should be ascribed to paralysis of the vagi and an action upon the nerve-centres controlling the blood-vessels, first stimulating and then paralyzing them. According to others, they do

not depend upon any action upon the vagi, but solely upon an influence directly exerted on the intra-cardiac ganglia.

Whatever be the physiological explanation of the fact, there can be no doubt that in the greater number of experiments on man the pulse-rate falls under the full influence of quinine, whether in health or in disease, and that at the same time its force is diminished. This action is generally believed to be attended with a fall of temperature as its necessary consequence: but, although such is probably the case, it occurs by no means uniformly unless the dose be very large. In the latter case it appears to depend in part and on the one hand upon the slowness, and on the other hand upon the hurried and inefficient character, of the respiratory movements, as well as upon a like action of the heart. (Compare Sée et Rochefontaine, *Archives gén.*, Mars, 1883, p. 374.) Theoretically, in moderate doses quinine stimulates the trophic centres and quickens tissue-change, but in larger doses it has the opposite effect. The important sphygmographic experiments of Dr. Mary Putnam Jacobi upon a human brain exposed by an opening in the cranium confirm these statements, and prove that "by a tonic dose of quinine (5 grains) the energy of the cardiac systole is increased; the tonus and elasticity of the walls of cerebral vessels are also increased, so that the blood is forced rapidly on through the capillaries, thus diminishing the resistance to the cardiac systole. More blood is admitted to the brain, but the intercranial pressure is lessened." But after a sedative dose of 20 grains there resulted "diminished energy of the cardiac contractions, unfilled cerebral arteries, and great diminution in intercranial pressure."

Numerous observations concur in rendering it probable that in very large doses quinine may lessen the coagulability of the blood, and that this effect is sometimes produced by medicinal doses. A case is recorded in which a neuralgic woman suffered an attack of purpura from taking a very small dose of quinine (*Boston Med. and Surg. Jour.*, Dec. 1883, p. 587). It has also been affirmed, and on the other hand denied, that the number of the white blood-cells and their power of emigration are diminished by the operation of quinine. The affirmative proposition seems to be the more probable. It has been maintained by Binz and Scharrenbroich, who state that quinine reduces the amœboid activity of the white corpuscles, and that these elements are actually killed in solutions of 1 part of sulphate or muriate of quinine in 3000, or even 4000, parts of blood-serum. Quinine salts also diminish, or even arrest, the migration of these corpuscles. It also appears that the white corpuscles which emigrate have, for the most part, a single nucleus, while previously the greater number are multinucleated; and further, that the red corpuscles become larger under the influence of quinine. Cutler and Bradford (1878) found that after a large dose of sulphate of quinine there is in health a slight diminution of the red, and a marked increase in the number of the white, corpuscles. Binz and Ransonné state that while quinine does not alter the shape or size of the red corpuscles, it lessens their power of absorbing oxygen (Husemann, etc., *Die Pflanzenstoffe*, 1884, p. 1439).

In regard to the action of quinine upon the nervous system, experiments upon animals demonstrate that in large doses it deranges, enfeebles, and finally extinguishes, nervous action. The animal subjected to observation staggers, becomes agitated, and sometimes convulsed, and then assumes a dull, inanimate expression and subsides into a state of apparent debility and torpor, with impaired vision and widely-dilated pupils. According to Chirone, there is also progressive anæsthesia, which is produced about equally by quinine, cinchonine, and cinchonidine (*Med. News*, xl. 406). When 5 or 6 grains of sulphate of quinine are taken by an adult man at a single dose, or two or three times that quantity in the course of 12 hours, there is apt to be some heaviness and confusion of thought, headache, buzzing in the ears, vertigo, and unsteadiness of gait. Larger doses occasion, in addition, a sense of fulness, tension, and pulsation in the head; the face becomes suffused and animated; the eyes are bright; epistaxis sometimes occurs; the patient is restless and agitated, and complains of muscular twitching in the limbs. After several hours these phenomena are followed by some degree of exhaustion and a disposition to sleep, with slight torpor and muscular debility. If as much as 30 grains are given daily for several days, in divided doses, there may be observed great depression, apathy, somnolence, unsteadiness of gait, impaired sight and hearing, and dilatation of the pupils; the general sensibility is obtuse and the limbs tremulous. If, finally, the dose has been excessive, complete loss of consciousness may occur, the sight and hearing fail, the skin loses its sensibility, and the limbs their power of motion.

The usual and most probable interpretation of these phenomena is that quinine in moderate doses primarily stimulates the nervous centres and increases the amount of blood circulating in them; that in excessive doses it diminishes the supply of blood to the

same parts; and that this diminution results mainly from the depressed power of the heart. The most important fact in support of this view is that the giddiness, confusion of sight, and faintness caused by quinine subside as soon as the patient lies down.

On the *respiratory organs* the primary action of quinine is stimulant, slightly increasing the rate of breathing. Poisonous doses occasion dyspnoea and noisy respiration, which is also jerking, interrupted, retarded, and finally arrested, death taking place with symptoms of asphyxia. In some cases the sputa have been bloody. Doubtless the latter phenomena are due to a paralyzing influence exerted by quinine upon the respiratory nervous centres, coupled with an analogous action of the drug upon the cardiac nerves and ganglia. According to certain experiments upon rabbits (Strassburg), quinine does not diminish the exhalation of carbonic acid, even while it lowers the temperature.

On the *digestive organs* small doses of quinine, as of all pure bitters, stimulate the appetite and digestion, but in large and continued doses it irritates the stomach and confines the bowels at first, although it may afterward cause diarrhoea.

The fact that when quinine cures intermittent fever it also contracts the *spleen*, if that organ is enlarged, is a familiar one. It is also known that when quinine is largely administered to animals for various experimental purposes the spleen is found pale and hard and its capsule wrinkled. These effects occur even when all the nervous trunks supplying the organ are divided. Hence, it is concluded that quinine must act upon the internal nervous system of the spleen (Binz). The function of the organ, it is added, being to form the white corpuscles of the blood and to prepare various oxidized substances, and especially uric acid, for excretion, and quinine having the power of restraining both of these operations, necessarily the organ appropriated to them must contract in proportion to the restriction of its functions.

Quinine, being excreted with the *urine* to the extent of at least one-half, sometimes occasions irritation of the urinary passages, causing in different cases micturition, retention of urine, and even hæmaturia. Karamitsas, a Greek physician, relates (*Bull. de therap.*, xevii. 53, 108, 149) seven cases of hæmaturia attributed by him to this cause. One was in a girl whose skin had merely been bathed with a solution of quinine (?): in the other six cases the hæmorrhage occurred independently of malaria, and usually two or three hours after the medicine had been taken. The connection between the alleged cause and the hæmaturia in these and other similar cases has been called in question, and the bloody urine has been regarded as merely symptomatic of hæmoglobinuria. If irritation already exists in the bladder, quinine usually appeases it. These facts tend to explain the occasional occurrence of *abortion* or premature labor in females taking very large doses of quinine for the cure of periodical fevers, particularly when the tendency to the accident is increased by general ill-health or malarial cachexia. There is more reason to apprehend abortion or premature labor from such causes than from the use of moderate doses of quinine, which rather tend to counteract their injurious action. When, under such bad conditions of health, labor sets in with feeble and ineffectual pains, quinine in moderate doses will, like other spinal nerve-stimulants, often render the contractions of the uterus more energetic and efficient. That there is no tendency in quinine to bring on contractions in the gravid and quiescent uterus has been proved by abundant experience. Burdel reports several cases which demonstrate that enormous doses of it can be taken without injury to the embryo and without shortening the duration of pregnancy, and is supported by experiments upon animals with young and near the end of gestation. Among the latter must be included the case of a gravid cat that died of direct poisoning by quinine without a sign of labor.

Quinine and cinchonine both occasionally produce erythematous or papular *eruptions* (urticaria, roseola) of the skin, which sometimes are followed by exfoliation of the cuticle. A very large number of cases illustrative of this subject have been published in the last few years. In some of them the eruption constituted the chief phenomenon of the attack: in others, numerous severe symptoms of a different nature occurred. Of the latter class the following case will serve as an example: A lady who had on a previous occasion been afflicted in the same manner took 5 grains of sulphate of quinine for a quotidian intermittent fever. "The exanthema was vivid red and of an urticarious character, extending over the entire surface, with wheals on the chest, sides, and flexures of the joints coalescing and running together, covering large spaces of integument. . . . Her face, eyelids, and neck were puffy and œdematous, there was great dyspnoea and præcordial oppression, the fauces were swollen and inflamed, with dysphagia and sensations of choking, a very rapid pulse, much febrile disturbance, considerable deafness,

dilated pupils, severe headache, a wild expression of countenance, extreme restlessness, and intolerable itching" (King). A case almost identical in its phenomena occurred to Köbner. In it also the patient had been similarly affected by quinine several years before. (Compare Farquharson, *Trans. Clin. Soc.*, xii. 25; Franck, *Med. Record*, xxi. 627.) As exanthems of an analogous character sometimes accompany the first stage of a paroxysm of intermittent fever, it has been suggested that malaria, and not quinine, might be their cause. A sufficient answer is that in Köbner's case there was no malarial disease whatever, and the same is true of many cases that have occurred since the administration of quinine in various febrile diseases has been in vogue. Moreover, it has been observed that in manufactories of quinine such eruptions are not uncommon. A lichenoid eruption has been produced by a bath containing sulphate of quinine. When this salt is applied to the denuded cutis it occasions severe burning and smarting pain, and sometimes forms a superficial eschar. It is declared by Giulio not to be absorbed by the skin, even under the most favorable circumstances (*Phila. Med. Times*, xi. 403).

Quinine in excessive doses may be dangerous, and even fatal, to life. A description of the symptoms in one or two cases will include all that is important. In 9 hours after 3 drachms of sulphate of quinine had been taken at a single dose the patient, an adult male, lay motionless and pallid, the fingers were bluish and cold, and the whole surface cool, the respiration slow and suspirious, the pulse regular, but slow and hardly perceptible, the pupils widely dilated, the sight and hearing almost extinct, and the voice extremely feeble; the thirst was great, the tongue pale and moist, and the breath cold. In another case (Vorlies, *Trans. Amer. Med. Assoc.*, xxx. 411) a woman threatened with a congestive chill took more than 1300 grains of quinine within 3 days. On the second day she became blind. A week afterward she was extremely weak, almost pulseless, and barely able to comprehend questions, but her hearing was only slightly impaired. The face was pale, the conjunctiva anæsthetic, and there was no perception of light. The interior of the eyes showed no trace of blood-vessels. Three months later the condition of the eyes was nearly stationary, but the health in other respects was good. The ocular phenomena in this case are similar to those observed by Grüning, Michel, and others. It is said that no case of permanent blindness from quinine has been recorded (*Edinb. Med. Jour.*, xxvii. 942). A case is related by Grüning (*Med. Record*, xviii. 608) in which 80 grains of quinine produced deafness and blindness. The condition of the eye resembled that just described, and vision was not fully regained for several months. Others have been published by Michel and by Knapp (*Amer. Jour. of Med. Sci.*, Oct. 1882, p. 616). It has been disputed whether the deafness due to quinine is accompanied by an anæmic or a congested state of the internal ear (*Boston Med. and Surg. Jour.*, Mar. 1883, p. 220), and the highest authority is upon the side of the latter opinion. It seems singular that the drug should congest the ear and anæmiate the eye. It indeed has been alleged that the eye is congested primarily by the medicine, but of this statement the evidence is insufficient (Roosa, *Med. Record*, xxiii. 145). Although it has been alleged that no case of death from quinine has occurred (Binz), these symptoms were observed in four recorded fatal cases. One, a child of eight years, died from taking 8 grains of this salt in two doses within three hours. In other cases partial loss of hearing or of sight has followed the use of the medicine, and lasted for several weeks. On the other hand, enormous doses have sometimes been used without any serious consequence.

Sensible physiological effects are seldom observed when the dose of sulphate of quinine is less than 4 grains; those produced by a dose of 6 grains may be expected in about an hour, and by 15 grains in about a quarter of an hour. The duration of the sensible effects is in the direct ratio of the dose administered; those from 6 to 8 grains may last for two or three hours, and from 15 grains for four or five hours. Larger doses maintain their action for a proportionately longer period.

Other things being equal, the functional disturbance is of shorter duration in children than in adults, but in old age they are apt to be both more decided and more prolonged. These facts depend probably upon the more rapid elimination of quinine by the kidneys in young than in old persons. It is more operative, in the same dose, in females than in males. Burdel, who studied the action on the new-born child of the milk of a woman who was taking sulphate of quinine, states that he has known infants to be fatally poisoned in this manner. He holds, what is very probable, that the danger is greatest when the medicine is taken upon an empty stomach and during the first four or five months of the infant's life. He adds that when it becomes necessary to administer quinine soon after delivery the injurious effects upon the child may be prevented by giving it with the meals, and by emptying the mother's breast artificially 3 hours after its administration.

Neither Dolan nor Bunge, on the other hand, could find any of the drug in the milk of a nursing woman who was taking it (*Practitioner*, xxvi. 57; xxvii. 168).

Like many other medicines, quinine is stimulant in small but sedative in large doses; but it differs from other stimulants in the duration of its action, which is long sustained, and entitles it to be called a tonic stimulant. In the smallest medicinal doses it is purely tonic, in larger doses stimulant, and in the largest sedative, acting in each case upon the cerebro-spinal nervous system and through the ganglionic nervous system upon the heart. It possibly also modifies the vital elements of the blood, in large doses checking their development. It appears, therefore, that by its combined influence upon the nervous system and upon the blood it is capable of restraining all the processes which develop heat, organic changes, and muscular motion.

The experiments and observations made during the last century gave rise to a belief that cinchona had a special power of correcting or limiting putrefaction and fermentation, and hence it was employed as a specific remedy for all diseases in which these processes were conceived to be taking place in the blood. Among them were the continued and periodical fevers. Modern doctrines regarding these diseases involve a similar idea, and the efficacy of quinine in curing them is attributed to its power of destroying and disintegrating vibriones, bacteria, and analogous organisms. It is in fact "a powerful anti-zymotic" (Binz). 1 part of quinine dissolved in 20,000 parts of water will in a few minutes begin to enfeeble parameciæ, in two hours will destroy their vitality, and in a few hours more cause their disintegration. Quinine retards or arrests the alcoholic and other fermentative processes, including putrefaction and certain morbid ferments. This action it is claimed to possess upon diphtherial exudations and upon the sputa of pulmonary gangrene. Gieseler determined that fresh muscle could be preserved in a solution of $\frac{1}{2}$ of 1 per cent. of quinine sulphate, and Binz that such a solution exhibited more power of preventing the formation of new bacteria than in destroying those already existing. It appears probable that no amount of quinine capable of destroying micro-organisms in the blood of man could be taken by him without endangering life. Such, at least, is the conclusion of Vulpian and Rochefontaine, Baxter, Binz, Fickert, and others (Husemann, *Die Pflanzenstoffe*, 1884, p. 1437).

There appears to be some differences between quinine and cinchonine in their mode of action. Thus the latter is said to be more poisonous to frogs and dogs than the former. In man also sulphate of cinchonine does not so speedily produce buzzing in the ears and disordered action, but, on the other hand, it more constantly occasions, and in smaller doses, a peculiar pain and sense of oppression in the frontal region, distress about the præcordia, subsultus tendinum, general debility, and faintness.

Medical Uses.—*Malarial Diseases*: The anti-zymotic doctrine above described is thought to be supported by the power of quinine to prevent and cure malarial diseases, which are assumed to depend directly upon the introduction into the blood either of certain low and extremely minute organisms, or of a specific poison which accumulates in the system and tends to destroy its albuminous elements with the production of fever. This doctrine is at present only probable, perhaps only hypothetical, and yet none other so well explains the fundamental practical rule that the paroxysm of fever is not directly prevented by the primary action of quinine, whose phenomena are evident, but that the curative operation is developed hours or even days after those sensible phenomena have disappeared. No medicine which operates simply by exalting or depressing the organic actions so distinctly possesses this peculiarity, which is difficult to comprehend except upon the supposition that its eliminative or antidotal, and not its dynamical, action is the chief agent in the cure of miasmatic diseases. Moreover, the efficient dose of quinine in these diseases bears no relation to the sensible effects which it produces: indeed, in all simple intermittents, and in the great majority of other forms of periodical fevers, the cure is effected without the necessity of inducing the slightest degree of quinine intoxication. It is possible that in addition to the modes of action here alluded to quinine may be curative of malarial diseases by directly supplying to the blood that peculiar constituent upon which animal fluorescence depends, and which is found to be greatly diminished at least in chronic intermittent fever, and to regain its normal proportion as the patient renews his health. (Rhoads and Pepper, *Penna. Hosp. Rep.*, 1868, p. 269; Binz, *Amer. Jour. of Med. Sci.*, Oct. 1881, p. 552). While, as we think, the antidotal power of quinine cannot be refused the chief place in the cure of periodical fevers, we must not lose sight of the fact that they were cured from the beginning of time down to the discovery of cinchona by a great number of agents, and that they continue to be so cured even in

cases where quinine has failed of its expected effect. It is equally certain that periodicity, and not malarial periodicity, is the essential condition of its curing a number of diseases which assume that type, as is more fully set forth in a subsequent paragraph.

But whether the salts of cinchona act by modifying the powers of the nervous system or as antidotes to a material morbid cause, they are efficient in *preventing* as well as *curing periodical fevers*. Their power has been tested in all parts of the world; and it is now certain that a person under the impression of a dose of quinine or cinchonine, even within the limits of sensible cinchonism, may be exposed to malarial influences without danger. Indeed, a dose of from 2 to 5 grains (Gm. 0.12–0.30) once or twice a day has been found sufficient for this purpose.

Formerly the notion prevailed that in order to render the treatment even of simple periodical fevers efficient the gastro-intestinal tube should be thoroughly cleansed by emetics and cathartics, and that sometimes mercury should be exhibited. Experience has proved that these methods, founded upon theory for the most part, are generally unnecessary and sometimes injurious, the conditions they are intended to remove depending mainly upon the malarial poisoning for which quinine is the specific cure. It may, as a rule, be administered without preliminary medication in the dose of from 5 to 8 grains (Gm. 0.30–0.50) during the intermission in *simple intermittents*. The result of a careful observation of different methods of administering the medicine has been clearly to prove that the anti-febrile influence of quinine does not coincide with its physiological operation either in time or degree. A period of at least 12 hours should, if possible, intervene between the last dose of the medicine and the hour of the expected attack, and according to the severity of the paroxysms the dose should be large or small, single or divided. When once the paroxysms have been arrested, the medicine should be suspended until 24 or 36 hours before the seventh day, reckoning from the beginning of the last paroxysm, when it should be repeated in the original dose. At the next hebdomadal period it should be prescribed in half the quantity, and still further diminished in the third week. In *congestive intermittents*, while it may be necessary sometimes to employ depletion, evacuations, and revulsives and the stimulant shock of the cold dash, these and all other agents are comparatively worthless without quinine. It must be administered to the extent of not less than 30 grains (Gm. 2) during the intermission—by the mouth preferably, but if this cannot be, by the rectum, or even hypodermically. Immediate effects are not to be expected.

Hæmorrhagic malarial fever is alleged by Dr. McDaniel to be by no means as amenable to the treatment by quinine as other malarial fevers. From a large basis of observation by himself and others he draws the conclusion, "that quinine is not only not the effective and reliable remedy as is now widely taught, believed, and practised, but that it is, on the contrary, an uncertain, and even a dangerous, agent in this disease, and often seems to determine an unfavorable result" (*Medical News*, xliii. 561). This judgment, which is apparently borne out by the facts adduced in its support, is nevertheless impugned by Dr. Webb, a colleague of the reporter, who is also in full accord with the general medical experience of the region in which this disease occurs.

In *remittent fever* a preparatory emeto-cathartic treatment appears to be more distinctly indicated by the gastro-hepatic symptoms than in intermittent fever; yet observation proves that in this case also the local disorders are under the control of the miasmatic poison, and that when it is eliminated or neutralized they cease. If the physician is able to choose his time, the medicine should be administered as soon as the remission sets in, and from 12 to 18 grains (Gm. 0.80–1.20) of quinia should be given in two or three doses at intervals of an hour; but if the paroxysm has already begun and if the symptoms are urgent, as occurs in the congestive forms of the disease, no time should be lost; the medicine should be administered in doses twice as large as those just named, and at shorter or longer intervals according to the duration of the remission. After control has been obtained over one paroxysm, the medicine may be exhibited in half the original doses, or less, for several periodical revolutions.

The prevalence of *yellow fever* in certain localities where periodical fevers also prevail gave rise to the grave error that its nature is the same as theirs, and that it may be cured by their specific remedy. The experience of competent judges has led to the following conclusions: 1. That quinine is not a specific for yellow fever, as it is for periodical fevers of every type; 2, that in mild cases, which would probably recover under good nursing and an expectant treatment, the medicine may sometimes hasten recovery; 3, that, on the whole, the results depending upon quinine are no better than—if, indeed, they are as good as—those of the treatment of symptoms which is sanctioned by general experience,

and which the skill of the physician must modify to suit the genius of each epidemic of the disease.

Various *inflammatory affections* assuming a periodical type under the miasmatic influence are more successfully treated by quinine than by any other means. The more important of such affections are *pneumonia* and *dysentery*. In like manner, accidental periodical *hæmorrhages* have ceased under the influence of quinine, including even *epistaxis* (*Bull. de thérap.*, xcvii. 373; *Med. Record*, xxi. 541).

Many functional disorders of the spinal nervous system assume more or less distinctly a periodical type, quite independently of a specific poison. Among these may be enumerated *spasmodic asthma*, *laryngismus stridulus*, *whooping cough*, periodical *palpitation of the heart*, *hicough*, and, above all, *neuralgia*. In the last-named disorder quinine divides with arsenic the honor of the greatest number of cures, as it also does in malarial fevers and other diseases of like origin. Cases of intermittent *paralysis* of the hemiplegic form, and also of periodical *aphonia*, have been cured by the same means; but they were miasmatic in nature. In these cases the operation of the remedy was generally stimulant and not sedative, since they were cured by comparatively small doses of quinine. But in some of the above, and still other affections of the nervous system, the cure has been brought about by large or sedative doses of quinine. Thus, in *whooping cough* it is claimed that when muriate of quinine is prescribed in doses of as many times a grain and a half as the patient numbers years, and especially when it is administered in the evening, unless it is carelessly given, it never fails either to cure the disease absolutely or to render it mild and innocuous, provided serious complications do not exist.

The curative effects of quinine in *sunstroke* are attested by numerous physicians, especially in the East Indies, where this accident is of more frequent occurrence than elsewhere. It is claimed that, whereas the mortality from heat-apoplexy in that country was formerly more than 50 per cent., the success of the treatment by quinine has been constant. The medicine is most effectually administered hypodermically by several punctures, in each of which $1\frac{1}{2}$ grains (Gm. 0.10) is introduced.

The history of the treatment of *acute articular rheumatism* by cinchona and by quinine is instructive, for it leads one to entertain serious doubts concerning the mode of action of these medicines. More than a century ago bark came into vogue for the cure of rheumatism, and was administered in doses representing not more than 2 or 3 grains of quinine, after depletion, emesis, and purgation. Until the introduction of quinine its efficacy was almost unquestioned, yet nothing can be plainer than that bark as formerly used can produce no such effects as quinine employed according to the fashion of the present day. The former could only act as a stimulant, the latter only as a sedative. This was the first disease in which the modern doctrine of treating febrile affections was applied—a doctrine which would seem to teach that disease is in its phenomena alone, and not in the organic condition out of which they spring. Enormous doses of the medicine were given, even to the amount of 200 grains in one day; but although far smaller and less poisonous doses were usually administered, and marvellous cures were fully set forth, the common sense of physicians revolted against the method, and it is now practically abandoned. Quinine, however, in tonic doses is of service in that condition of debility which is apt to follow or accompany the use of the most efficient treatment for acute articular rheumatism—the alkaline. It prevents the development of the scorbutic cachexia, and an increase of the weakness that denotes a tendency to such a result. It is also indicated, but less strongly, after the treatment by salicylic acid or the salicylates.

A precisely similar succession and antagonism of opinions to that which has just been sketched occurred in the history of the use of bark in *typhus*. Originally employed to counteract "putridity," it was used beneficially, because it acted as a stimulant, and was combined with other stimulants, as in the famous and still officinal "Huxham's tincture." In more recent times quinine was employed as an antiphlogistic and sedative in very large doses, and not a few witnesses were found to give the most positive testimony in its favor. That they were utterly mistaken is now certain. Quinine has not been shown to be of any service in typhus except at the critical stage, when a full tonic dose may reduce the pulse and give a favorable turn to the disease.

One of the latest and highest authorities in medical science uses the following language: Quinine does not put an end to an attack of *typhoid fever*, as it does to one of intermittent fever. In the first-named disease it has no specific operation, but only so weakens the putrid ferments that they run their career less destructively. . . . When quinine is useless, the disease must either have assumed an exceptional and complicated form or the medicine must have been imperfectly administered (Binz). This author

reproaches those physicians who treat typhoid fever expectantly, and wait and watch who will hold out longest, the patient or the fever. Perhaps it may be better so to wait than to make use of means which tend to aggravate the patient's danger as well as to increase his discomfort, and which lessen neither the duration of the disease nor its rate of mortality; and quinine does neither. The error of practice in using this treatment is, that its results are the reverse of flattering to the sagacity of its promoters, or of being satisfactory to the philanthropic feelings we must give them the credit of possessing; the error in theory consists in treating fever as if it were absolutely limited by temperature and pulse-frequency, and as if nothing more essential lay behind these symptoms of the process. The mischievous results of treating typhoid fever with sulphate of quinine appear to be explicable by the large doses of it administered, or as much as 35 or 40 grains for an adult man given in three or four doses in less than an hour. In December, 1882, Hardy called the attention of the Paris Academy of Medicine to the fact that within three months four cases of sudden death had occurred in the hospitals among patients treated with large doses of quinine (*Archives gén. de Méd.*, Jan. 1883, p. 114). It is greatly to be apprehended that a portion of the quinine may reach and irritate the intestinal ulcers and increase the risk of perforation, one of the gravest dangers of the disease.

What has been said concerning typhus and typhoid fevers is equally applicable to *puerperal fever*, *scarlet fever*, *small-pox*, and *erysipelas*. There is very little doubt that tonic and stimulant doses of quinine are serviceable in them, and that sedative doses of the medicine are mischievous. In each affection it is useful in proportion as the symptoms assume a typhoid character; thus it is advantageous in all cases of *septicæmia*, whether arising from primary blood diseases or from traumatic causes, but in this, as in the other affections enumerated, only in small and repeated doses. It has even been employed before and after surgical operations to prevent *septicæmia*, but evidently its influence, if any, would be extremely difficult to determine. This medicine has also been alleged to be more efficacious than any other in the radical treatment of *diphtheria*, but as yet satisfactory clinical proof of the statement has not been furnished. As a tonic in this disease its utility is generally recognized. The same may be said of its use in the treatment of *asthenic pneumonia*, and of *hectic fever* from whatever cause it may arise. In the numerous allied cases also of *profuse sweating* connected with general debility from exhausting diseases, whether during their progress or following their active symptoms into convalescence, quinine, especially with aromatic sulphuric acid, is one of the most reliable remedies that can be employed.

We have not in the preceding paragraphs alluded to the employment of sulphate of quinine in purely inflammatory diseases—those of all others, one would suppose, which would illustrate the sedative virtues of the medicine. But neither in meningitis, pleuritis, pericarditis, or peritonitis, nor in any mucous inflammation, does it appear to have been put to the test. There remains *pneumonia*, which has long been the *pièce de résistance* upon which the virtues of active medicines have been tested. It has not escaped the administration of heroic doses of quinine. In Stockholm, Jürgensen (1871) stated that in a series of 200 consecutive cases twenty-four were fatal, or a mortality of 12 per cent. But his own statistics of the same city for 1851, when certainly the quinine treatment had not been devised, present a mortality of only 9.8 per cent., and in five of the sixteen years from 1840–55 the mortality was less than 12 per cent. This distinguished physician gave “in highly febrile states to an adult 77 grains (Gm. 5), and to a child under one year 15 grains (Gm. 1), and always in one dose.” It is very desirable that a medicine as precious and costly as quinine should not be squandered, and it certainly seems to be wasted when it is administered so profusely with no better results than these. In this country a similar, but a somewhat less extreme, method has been recommended by Palmer (1877), who gave, as near as possible to the beginning of the attack, from 6 to 10 grains of quinine with from $\frac{1}{4}$ to $\frac{1}{2}$ grain of morphine, repeating the quinine in doses of from 4 to 8 grains once in from two to three hours, and continuing them until from 30 to 50, and sometimes 60, grains were given. Of this treatment we are told: “The effects desired, and certainly as a rule produced, are a decided reduction of temperature, a marked diminution in the frequency of the pulse, a decided moisture of the skin or free sweating, a slower and more easy respiration, or relief from pain and the feeling of fulness of the chest, a diminution of the cough and of the tenacious and bloody character of the expectoration; and, in short, not only is there a checking of the fever, but of all evidences, general and local, of the pulmonary engorgement and inflammation.” These are very remarkable effects, and the statement of them would have

acquired a much higher value if it had also included the number of cases for which the treatment was used, the ages of the patients, the type and grade of the disease, its mortality-rate, and the other remedies besides quinine and morphine that were employed. Meanwhile, so far as we can learn, since the original recommendation of this method by Jürgensen, no other reports proceeding from an authoritative source have been published to confirm it.

In close pathological relation with the above-mentioned asthenic states are numerous local affections in which quinine is of great value. Such are *scrofulous ulcers and abscesses, scrofulous inflammations of the eye, chronic mucous fluxes of the pharynx, larynx, bronchia, stomach, bowels, and urinary organs*. It is one of the best remedies for scarlatinous and other forms of *albuminuria*, especially when it is associated with tincture of chloride of iron.

In auditory *vertigo* (mal de Ménière) the persistent use of quinine has in several cases removed the complaint entirely. Charcot, who proposed this method, insists on the administration of 10 or 12 grains of quinine daily for at least a month, although it is apt at first to aggravate the symptoms, and then the resumption of the medicine after its suspension for a week or two (*Med. Record*, xviii. 602). Ménière himself found that it lessened or removed the vertigo and modified the deafness, but does not profess that quinine, more than any other medicine, is a cure for the disease (*Monthly Abstract*, July, 1881, p. 407). These results are confirmed by Féré and Démars (*Bull. de thérap.*, cii. 133). Although quinine has no power of originating contractions in the gravid uterus, it undoubtedly during *slow labor*, with insufficient expulsive pains and an exhausted condition of the system, revives the uterine energy, favors the rapid and safe termination of labor, and tends to prevent exhausting hemorrhages. The dose should not exceed 10 grains (Gm. 0.60). Le Diberder claims that sulphate of quinine in the dose of 6 grains (Gm. 0.36) twice a day is an efficient remedy for *fissures of the nipples*, and that no active local treatment need be employed at the same time.

The state of muscular debility and nervous excitability which often occurs during the second stage of *whooping cough* is apt to be improved under the influence of bark or quinine, as has been well known since the time of Cullen. More recently, sulphate of quinine has been used in free solution as a draught, or else atomized, under the impression that its curative action was local; indeed, the tannate of quinine has been recommended especially (Binz) for its topical influence on the fauces and larynx. But equally good results have been obtained from the sulphate when administered by the rectum. It is apt to fail in severe cases and when complications exist. The dose by the mouth should be from $\frac{1}{2}$ grain to 3 grains three times a day.

Nay fever has been treated successfully with injections into the nasal passages of a warm watery solution of quinine of the strength of from $\frac{1}{4}$ to $\frac{1}{10}$ of 1 per cent. At the same time it should be given internally in doses of not less than 5 grains (Gm. 0.30) three times a day.

A solution of quinine of the strength of 2 or 3 grains in an ounce (Gm. 0.13–0.20 in Gm. 32) of water has been used with advantage as an injection for *gonorrhœa*. Probably by a similar mode of action it has been found to greatly relieve the *tenesmus* attending micturition in cases of *resical catarrh* and *villous growths* near the neck of the bladder, whether injected into that organ or administered by the mouth. It will be remembered how large a proportion of sulphate of quinine is eliminated with the urine. Most probably it acts both substitutively and by limiting the putrefaction of the mucus in the bladder. It has also been injected into the pleural cavity in cases of *empyema*, and applied as a dressing to *ulcers* and suppurating *sinuses*. A solution of 4 grains to the ounce has been applied with alleged advantage in the treatment of pseudo-membranous *conjunctivitis* (Tweedy, *Amer. Jour. of Med. Sci.*, Apr. 1882, p. 592). A strong solution of the salt is said to relieve *pruritus ani* and *pruritus vulvæ*. In these cases there is no sufficient reason for believing that it acts otherwise than as a substitutive irritant.

WARBURG'S TINCTURE is the name of a preparation which was for a long time famous as a nostrum, the secret of which was obtained by Prof. Maclean of the Army Medical School in England. This distinguished physician had on many occasions witnessed the efficacy of the medicine in India when quinine had proved unavailing. Its composition is as follows: *℞. Aloes* (Socot.) lb. j; *Rad. rhei* (chinesis.) Sem. angelicæ, Confect. Damocratis, āā $\mathfrak{z}\text{iv}$; *Rad. helenii* (s. enulæ), *Croci sativi*, Sem. fœniculi, *Cretæ ppt.*, āā $\mathfrak{z}\text{ij}$; *Rad. gentianæ*, *Rad. zedoariæ*, *Pip. cubebæ*, *Myrrhæ elect.*, *Camphoræ*, *Bolet. laricis*, āā $\mathfrak{z}\text{j}$. These ingredients are to be digested with 500 ounces of proof spirit in a water-bath for 12 hours; then expressed, and 10 ounces of disulphate of quinine added to the mix-

ture, which is then replaced in the water-bath until all the quinine is dissolved. The liquor when cool is to be filtered, and is then fit for use. The tincture is administered in the following manner: "½ ounce (half a bottle) is given alone without dilution, after the bowels have been evacuated by any convenient purgative, all drink being withheld. In three hours the other half of the bottle is administered in the same way. Soon afterward, particularly in hot climates, profuse but seldom exhausting perspiration is induced. This has a strong aromatic odor, which is often detected about the patient and his room on the following day. With this there is a rapid decline of temperature and immediate abatement of frontal headache—in a word, complete defervescence—and it seldom happens that a second bottle is required; if so, the dose must be repeated as above." To the anticipated objection that, after all, the compound is "merely quinine concealed in a farrago of inert substances," the reply of Dr. Maclean is: "I have treated remittent fevers of every degree of severity contracted in the jungles of the Deccan and Mysore and at the base of mountainous ranges in India, on the Coromandel coast, in the pestilential highlands of the northern division of the Madras Presidency, on the malarial rivers of China, and in men brought to Nettley Hospital from the swamps of the Gold Coast, and I affirm that I have never seen quinine, when given alone, act in the manner characteristic of this tincture. And although I yield to no one in my high opinion of the inestimable value of quinine, I have never seen a single dose of it given alone, to the extent of 9½ grains, suffice to arrest an exacerbation of remittent fever, much less prevent its recurrence; while nothing is more common than to see the same quantity of the alkaloid in Warburg's tincture bring about such results (*Med. Times and Gaz.*, Nov. 1875, p. 540).

Administration.—The dose of sulphate of quinine as a tonic is 1 grain (Gm. 0.06) three or four times a day. More than this is likely to act as a sedative rather than as a tonic. In simple intermittent or mild remittent fever 6 or 8 grains (Gm. 0.40–0.50) are sufficient to avert the paroxysm; in severer cases of these affections the dose must be raised to 15 or 20 grains (Gm. 1–1.30), and in those of a malignant type to 30, 40, or even 60 grains (Gm. 2–4), given, in both of the latter cases, in divided doses. In all cases of periodical fever it should be administered *as long as possible before the expected paroxysm*, and generally in regular types as soon after a paroxysm as the stomach is able to retain it. Intermittent neuralgia requires doses sufficient to produce the physiological effects of the medicine in a marked degree, and the same is true of the various febrile and inflammatory affections in which the medicine is intended to produce sedation.

The most usual and efficient mode of administering sulphate of quinine in small doses is in solution, rendered more perfect and stable by the addition of aromatic sulphuric acid, in the proportion of 1 drop of the acid to each grain of the sulphate. It is also administered in powder enveloped in a wafer or in a thick mucilage, white of egg, or jelly, or in pills coated with gelatin or gold or silver leaf, in capsules, or, finally, in the form of compressed lenticular pills of disulphate of quinine. In all of these forms the concentrated action of the medicine upon the stomach tends to irritate it, and hence the solution already mentioned should be preferred. Its bitter taste may be masked by the addition of a little chloroform, and the mixture should be flavored with syrup or tincture of orange-peel, with extract of liquorice, or with syrup or fluid extract of liquorice-root. Tannic acid has been used to mitigate the bitterness of quinine in solution; it does so, indeed, but at the expense of rendering the medicine almost inert by forming with it a tannate. Moreover, it contains but 42 per cent. of quinine, whereas the sulphate contains 73.5 per cent. and the hydrochlorate 82 per cent. The last-mentioned salt is much less stable than the sulphate, but when freshly prepared is preferable on account of its superior solubility. It is a convenient associate for tincture of chloride of iron in solution. Spirit of nitrous ether is said to dissolve "quinine" in the proportion of about 2 drachms of the latter to an ounce of the former. By the rectum sulphate of quinine may be exhibited in the same doses and with nearly the same effect as by the mouth, provided it be given in watery solution. Probably the muriate is to be preferred for this purpose.

The hypodermic injection of a solution of sulphate of quinine has been extensively practised, but its tendency to cause pain, inflammation, abscess, gangrene, and even fatal tetanus (Ady), more than counterbalances the advantages derived from the facility of its administration and the promptness of its effect. The risks alluded to should restrict the use of this method to cases in which delay may be dangerous. It is claimed that if the solution be thrown into loose subcutaneous connective tissue this accident is not apt to occur, but sufficient proof of this claim is wanting. The bromohydrate of quinine is very soluble in water, and is alleged to be entirely unirritating, and therefore to be well

adapted for hypodermic use. It contains a larger proportion of quinine than the sulphate. It was, however, the use of this very preparation that caused the death above referred to. The dose for hypodermic injection of sulphate of quinine may be stated at from 2 to 4 grains.

QUININÆ VALERIANAS, U. S.—VALERIANATE OF QUININE.

Quininæ valerianas, U. S. 1870; *Chininum valerianicum*.—*Valerianate de quinine*, Fr.; *Baldriansaures Chinin*, G.

Formula $C_{20}H_{24}N_2O_2 \cdot C_5H_{10}O_2 \cdot H_2O$. Molecular weight 444.

Preparation.—Wittstein (1845) gives the following directions: Dissolve 1 part of valerianic acid in 60 parts of water; add to the solution 3 parts of quinine (recently precipitated alkaloid is preferable); heat the mixture to near boiling, filter when neutral and while hot, and set aside in a cool place. After several days decant the mother-liquor, evaporate at a temperature not exceeding 50° C. (122° F.), and dry the salt at a very moderate temperature. At a higher temperature the solution separates oily drops, which on cooling form an amorphous resinous mass dissolving with difficulty in water.

The salt was medicinally employed in 1843 by Castiglioni, and was in the same year prepared by Lucien Bonaparte from the sulphate by decomposing it with a valerianate. Stalman (1868) used for this purpose sodium valerianate; the quinine salt is taken up with alcohol.

Properties.—Valerianate of quinine crystallizes in colorless, pearly, rhomboidal tables or in white triclinic needles having a weak odor of valerianic acid, a bitter somewhat valerian-like taste, and a neutral reaction. The salt dissolves in 110 parts of cold and 40 parts of boiling water, in 6 parts of cold and 1 part of boiling 80 per cent. alcohol, and is easily soluble in ether (Wittstein). At 15° C. (59° F.) 1 part of the salt is stated to be soluble in 100 parts of water (*P. G.* 1872, *U. S.*) and in 5 parts of alcohol (*U. S.*); at 20° C. (59° F.) in 70 parts of water (Flückiger). The statement that the salt is slightly soluble in ether (*P. G.* 1872, *U. S.*) is an error. On adding dilute sulphuric acid to the aqueous solution it becomes fluorescent, and the odor of valerianic acid is rendered more apparent. Ammonia gives a white precipitate soluble in an excess of the precipitate and in ether, and with chlorine-water and ammonia an emerald-green color is produced. The salt is permanent in the air; it melts at 85° C. (185° F.), losing a portion of its acid (Stalman), and on cooling congeals to a glass-like mass; when strongly heated on platinum-foil it is decomposed, and burns slowly without leaving any residue.

Composition.—Wittstein obtained nearly 5 parts of valerianate from 3 parts of quinine, and determined the water to be over 33 per cent. $= 12H_2O$, and the quinine to be 51.355 per cent. L. Bonaparte regarded the loss in weight, ascertained by fusing the salt, to be water, and suggested the above formula. Stalman, by elementary analysis, found the crystallized salt to yield carbon, corresponding with the formula $C_{20}H_{24}N_2O_2 \cdot C_5H_{10}O_2$ (mol. weight 426), equal to 76.06 per cent. of anhydrous quinine.

Tests.—The aqueous solution should remain clear or become merely turbid (produce not more than a slight precipitate, *U. S.*) on the addition of test solution of barium chloride. The precipitate occasioned by ammonia-water should be readily dissolved on adding an excess of the latter (absence of cinchonine). The salt is tested for fixed impurities by incineration, for ammonia salt by lime or potassa, and for organic impurities, morphine, and other alkaloids by strong sulphuric and nitric acid, as described under QUININÆ SULPHAS.

Other Salts of Quinine.—QUININÆ ACETAS. Acetate of quinine crystallizes in long white needles on mixing hot solutions of sulphate of quinine (17 parts of the effloresced salt) and acetate of sodium (6 parts), and allowing to cool. It is sparingly soluble in cold water, but freely soluble in boiling water and in dilute acids. It contains 84 per cent. of quinine.

QUININÆ ARSENIAS. Arseniate of quinine, $(C_{20}H_{24}N_2O_2)_3As_2O_5 \cdot 3H_2O$. It is obtained in long white prisms by saturating hot solution of arsenic acid with quinine. The salt is freely soluble in hot but sparingly soluble in cold water, and contains 74 per cent. of quinine and 10.6 per cent. of As_2O_5 .

QUININÆ ARSENIS. Arsenite of quinine, $(C_{20}H_{24}N_2O_2)_3As_2O_3 \cdot 3H_2O$. Adler (1879) proposed the following process: 1 part of silver arsenite (prepared from sodium arsenite and silver nitrate) is mixed with 3 parts of hydrochlorate of quinine, and the mixture digested for a day with 70 per cent. alcohol. On spontaneous evaporation the salt crystallizes in white needles which are slightly soluble in water, but dissolve in 15 parts of cold and 6 of boiling alcohol, in 8 parts of chloroform, in 25 parts of ether, and in 20 parts of benzol.

QUININÆ BENZOAS, Benzoate of quinine, $C_{20}H_{24}N_2O_2 \cdot C_7H_5O_2$. It is obtained by dissolving 3 parts of benzoic acid and 8 parts of quinine in hot alcohol and crystallizing. It forms small prisms containing 72.6 per cent. of quinine and requiring at $10^\circ C.$ ($50^\circ F.$) 373 parts of water for solution.

QUININÆ CITRAS, Citrate of quinine. On saturating a warm solution of citric acid, or on decomposing a solution of quinine hydrochlorate by a solution of sodium citrate acidulated with citric acid, the salt, $(C_{20}H_{24}N_2O_2)_2 \cdot C_6H_5O_7 \cdot 7H_2O$, is obtained. It crystallizes from boiling water in small white prisms which at $12^\circ C.$ ($53.6^\circ F.$) require 806 parts of water for solution, and which contain 67.08 per cent. of quinine. The monobasic salt has a strongly acid reaction, and at $15^\circ C.$ requires 650 parts, and at $100^\circ C.$ 38.5 parts, of water for solution.

QUININÆ LACTAS crystallizes in silky needles on evaporating a solution of quinine in lactic acid; it is soluble in water and alcohol.

QUININÆ PHENYL-SULPHAS, Phenylated (carbolated) sulphate of quinine, $(C_{20}H_{24}N_2O_2)_2 \cdot SO_3 \cdot C_6H_5 \cdot 0.2H_2O$. 10 parts of crystallized sulphate of quinine are dissolved in boiling water or in alcohol, and an equivalent quantity (nearly 1 part) of carbolic acid is added to the solution. The salt contains 75.5 per cent. of quinine, crystallizes in needles, and, after having been washed with ether and recrystallized, has neither the odor nor caustic taste of phenol, is insoluble in ether and chloroform, but dissolves freely in alcohol and in a mixture of 2 volumes of chloroform to 1 of strong alcohol, and is more freely soluble in water than the sulphate, but is nearly insoluble therein in the presence of free phenol.

QUININÆ PHOSPHAS, $(C_{20}H_{24}N_2O_2)_2 \cdot H_3PO_4 \cdot 8H_2O$. Phosphate of quinine may be prepared by dissolving quinine in warm dilute phosphoric acid or by decomposing quinine hydrochlorate with sodium phosphate. It crystallizes from hot water in long silky needles which require at $10^\circ C.$ ($50^\circ F.$) 784 parts of water for solution, and contain 75.85 per cent. of quinine.

QUININÆ QUINAS, Kinate (quininate) of quinia, may be prepared by decomposing kinate of barium with sulphate of quinine and evaporating. H. Collier, who recommended it (1878) for hypodermic use, describes it as being amorphous, of neutral reaction, and freely soluble in water. A convenient strength of the solution is 1 part of the salt in 4 of the liquid.

QUININÆ SALICYLAS, Salicylate of quinine, is obtained as a curdy precipitate by double decomposition between hydrochlorate of quinine and salicylate of ammonium. The salt dissolves in 225 parts of water, in 120 parts of ether, and in 20 parts of alcohol, and crystallizes from the alcoholic solution in anhydrous prisms.

QUININÆ SULPHOVINAS. Carles (1878) prepares the neutral salt by dissolving 16.6 parts of sulphovinate of sodium and 42.8 parts of quinine sulphate, the former in 200, the latter in 600, parts of alcohol, mixing the solutions, filtering from the precipitated sulphate of sodium, and evaporating. It crystallizes with difficulty in prisms, dissolves in 3 parts of water at $15^\circ C.$ ($59^\circ F.$), in a less amount of alcohol, and dissolves likewise in acetic ether and glycerin, but not in strong ether or benzol.

QUININÆ TANNAS, Chininum tannicum. It is produced by adding a solution of 2 parts of tannin in 30 parts of cold water to a solution of 1 part of quinine sulphate in the same amount of water, with the aid of some sulphuric acid. It is a pale-yellow, amorphous, bitter, and somewhat astringent powder, which is slightly soluble in cold alcohol and water and melts when introduced into boiling water. By modifying the process so as to use water at a temperature not exceeding $70^\circ C.$ ($158^\circ F.$), using sulphuric acid barely sufficient to dissolve the quinine salt, washing the precipitate with water, and drying it at the ordinary temperature, tasteless tannate of quinine is obtained, according to A. Bernick (1878). In testing it Jobst (1878) recommends a weighed portion to be mixed with milk of lime, the mixture to be dried and exhausted with chloroform, on the evaporation of which the cinchona alkaloids are left behind.

Medical Action and Uses.—Valerianate of quinine, which is very unstable and often falsified, has no special therapeutic virtues which entitle it to an official rank. It has been vaunted in *nervous headache* and other *neuralgic* of the nerves of the head, face, and chest, and even in *hysteria* and *epilepsy*. When the joint actions of valerian and of quinine are desired, it is better to associate the sulphate of quinine or some other preparation of cinchona—quinetum, for instance—with the oil or the fluid extract of valerian, or to prescribe these substances separately. The *dose* of valerianate of quinine is 1 or 2 grains (Gm. 0.06–0.12).

TANNATE OF QUININE. Briquet relates that Barriswill, acting on the notion that in cinchona the union of bitter principles with quinine renders the latter less stimulating, combined tannic acid with it, so as to make a sort of artificial cinchona in a small bulk. But as this tannate contains but 40 per cent. of quinine and is very insoluble, the probability is that its action must be feeble. And so Briquet found it on clinical trial. He estimated its power at about one-eighth or one-sixth of that of the sulphate, and found that it dissolved very slowly in the stomach, is a weak febrifuge, cannot be used when large doses of quinine are needed, and indeed is suitable only for nervous affections and as a substitute for bark itself, and, finally, that its dose must be three times as large as that of the sulphate of quinine (*Traité du Quinquina*, 2ème ed., p. 515). Strangely, it afterward came to be recommended for its very lack of bitterness, although it was well known that this quality depended on its slight solubility (Becker, 1880), and several

German physicians lauded its virtues in *whooping cough*, as already stated (see QUININÆ SULPHAS), but overlooked the fact that even better results have been attributed to sulphate of quinine. Probably the internal use of sulphate of quinine and the application of a solution of tannin to the fauces and larynx would best secure the benefits of both medicines.

RANUNCULUS.—CROWFOOT.

Buttercups, E.; *Renoncule*, Fr.; *Hahnenfuss*, G.

Ranunculus bulbosus, Linné.

Nat. Ord.—Ranunculaceæ.

Origin.—The bulbous crowfoot grows in grassy fields and along roadsides throughout Europe, and has been naturalized in North America. It flowers from April or May till July or August.

Description.—The stem of this species is about 12 or 18 inches (30–45 cm.) high, and at its base enlarged to a depressed globular tuber which has the appearance of a tunicated bulb from the broad sheathing bases of the leaf-stalks. The radical leaves are, like the entire plant, hairy, long-petiolate, ternate, the lateral divisions sessile, the terminal one stalked, and all of a subrhomboid shape, three-cleft, toothed and wedge-shaped at the base. The stem-leaves are similar, but on shorter petioles. The flowers are about an inch (25 mm.) broad, have a reflexed calyx and roundish, wedge-shaped, glossy yellow petals, and produce globular heads of obovate akenes having a short curved beak. The plant is inodorous, but has a strongly acrid taste, which it loses after drying.

Allied Species.—All species of *Ranunculus* and some allied genera appear to possess more or less the acidity of the above. The following European North American species have occasionally been used:

RAN. REPENS, Linné. It resembles the preceding, but is without the bulbous base, produces long runners, has the divisions of the leaves stalked, a spreading calyx, and the akenes margined and furnished with a rather straight beak.

RAN. ACRIS, Linné. It differs from the creeping crowfoot in being taller and without runners, and in having the divisions of the leaves all sessile.

RAN. SCCELERATUS, Linné. It is very variable in size, smooth, with a hollow stem, roundish-reniform, three-cleft, and lobed or toothed leaves, small pale-yellow flowers, and oblong heads of ovate and short pointed akenes.

Constituents.—On distilling fresh crowfoot with water Braconnot (1818) obtained an acrid distillate having a radish-like odor and separating on standing thin glossy scales; the distillate of *Ran. repens* was not acrid. The acrid principle of *Ran. sceleratus* was found by O. L. Erdmann (1859) to be a golden-yellow volatile oil, which is readily changed into *anemonin* and *anemonic acid*. (See PULSATILLA.) Basiner (1881) observed that petroleum benzin does not extract this yellow oil from the distillate, but that this is dissolved by benzol and by ether; it may be extracted from the fresh plant by glacial acetic acid, and removed from this solution by agitation with the liquids named; caustic alkalies decompose the oil and destroy its acrid-narcotic action.

Medical Action and Uses.—Several of the numerous species of *Ranunculus* possess the same qualities as *R. bulbosus*. In its fresh state every part of the plant contains an acrid juice, and the bruised leaves, stems, and flowers applied to the skin occasion redness and vesication, and, if the action is prolonged, ulceration and even gangrene. It is stated that in Europe this plant was used by beggars to produce sores for the purpose of exciting pity and procuring alms. They cured their sores by means of mullein-leaves (*Verbascum thapsus*). The oil of *R. sceleratus* acts as an acrid narcotic, producing, in small doses, stupor and slow respiration, in larger doses also paralysis of the posterior and anterior extremities, and before death general convulsions. After death are found gastritis and cortical hyperæmia of the kidneys (Basiner, *Amer. Jour. of Phar.*, March, 1882, p. 130.) The bruised fresh plant (*R. bulbosus*) has been applied as a counter-irritant for the relief of chronic affections of the *larynx* and *bronchia*, but more particularly of chronic *rheumatism* and *sciatica*. It may still be so employed where other irritants are not at hand. It is not used internally.

RESEDA.—RESEDA.

Nat. Ord.—Resedaceæ.

Origin and Description.—The well-known *mignonette*, *Reseda odorata*, Linné, is indigenous to Northern Africa, and everywhere cultivated for its sweet-scented flowers, which are employed in perfumery.

RESEDA LUTEOLA, *Linné*.—Dyer's weed, *Weld, E.*; Herbe jaune, *Gaude, Fr.*; Wau, Gelbkraut, Harnkraut, *G.*—It grows in open places throughout Europe, and has been naturalized to some extent in the eastern part of the United States. It has a conical root of a radish-like odor and taste, and a furrowed, smooth, erect, and branching stem about 3 feet (90 Cm.) high. The leaves are alternate, crowded, oblong-lanceolate, near the base on each side with one tooth, narrowed into a short petiole, or the upper ones sessile, mostly undulate on the margin, light-green and shining. The flowers are in dense, finally erect, and elongated racemes, and have a four-parted calyx and four pale-yellowish petals, of which the lower one is linear and entire and the others larger and cleft. The capsule is depressed ovate, and terminates with four short erect horns. The herb is without odor and has a persistently bitter taste.

Constituents.—According to A. Vollrath (1871), the root of the mignonette contains *sulphocyanide of allyl* (oil of mustard), and it is probable that the same constituent exists in the root of weld. The herb contains *luteolin*, $C_{20}H_{14}O_6$, which was discovered by Chevreul (1830). It is obtained by concentrating the tincture, redissolving the crystalline precipitate in 150 parts of alcohol, diluting the solution with 20 parts of water, boiling, filtering, and crystallizing. It is in yellow, silky, inodorous, volatile needles of a faintly bitter and slightly astringent taste, sparingly soluble in water, slightly soluble in ether, soluble in 37 parts of alcohol, and freely soluble in warm glacial acetic acid, from which it crystallizes on cooling. Sulphuric acid dissolves it with a deep-orange color, acetate of lead precipitates it yellow, and ferric chloride is colored by it green, and afterward red-brown. By fused potassium hydrate it is decomposed into phloroglucin and protocatechuic acid. The seeds contain a green drying oil.

Medical Action and Uses.—*R. luteola* was formerly considered diaphoretic and alexipharmic; it was employed as an antidote to snake-bites and as a vermifuge.

RESINA, U. S., Br.—RESIN.

Colophonium, P. G.—*Rosin*, *Colophony*, E.; *Colophane*, Fr.; *Kolophonium*, *Grægen*, *harz*, G.

The residue after the distillation of volatile oil from the turpentine of *Pinus palustris* and of other species of *Pinus*.

Preparation.—The manner in which rosin is obtained is briefly described on page 1090. The color depends in a great measure on the degree of heat used in its manufacture. From a communication of I. Zacharias (1877), however, it appears that the amount of resin in turpentine increases with the age of the tree, and that the residuary product of the distillation becomes darker in color, probably in consequence of the greater heat employed in distilling off the oil.

Properties.—Rosin is a very brittle, pulverizable, transparent, or translucent resin, having about the density 1.070–1.080, breaking with a glossy and shallow conchoidal fracture, nearly tasteless and of a faint terebinthinate odor. It varies in color from a pale-amber to a dark red-brown, and is distinguished in commerce by the shade of its color, the darkest being called *black rosin*. For pharmaceutical purposes the amber-colored variety is used. *White rosin* is a light-colored variety which is rendered opaque by containing water, on the gradual evaporation of which it becomes translucent. It dissolves readily in ether, chloroform, alkalies, and in the volatile and fixed oils; at 60° C. (140° F.) it is slowly soluble in its own weight of alcohol or of glacial acetic acid. It softens at the heat of a water-bath, melts completely above 100° C.—some varieties at about 135° C. (275° F.)—and at a higher heat burns with a dense yellow and sooty flame. When heated to above 200° C. (392° F.) it may be distilled, apparently unchanged, with a current of superheated steam, but on dry distillation it yields *rosin oil*, which contains *colophene* (see page 1091), various hydrocarbons, and other products holding rosin in solution. Among the lower-boiling fractions of this rosin oil Kelbe and Warth (1882) have recognized caproic, isobutyric, cenanthylic, and other acids of the formula $C_nH_{2n}O_2$, and Renard isolated *amylene*, C_5H_{10} , boiling near 40° C., *hexylene*, C_6H_{10} , boiling near 70° C., and several other hydrocarbons. When rosin is mixed with lime and subjected to distillation volatile oils are obtained, from which, by fractional distillation, Fremy isolated *resinone*, $C_{10}H_{18}O$, which is limpid, readily inflammable, and boils at 78° C. (172.4° F.), and *resincone*, which is thicker, boils at 148° C. (298.4° F.), and seems to have the composition $C_{30}H_{48}O$.

Composition.—According to Maly (1861, 1864), rosin is the anhydride of *abietic acid*, $C_{44}H_{64}O_5$, and is converted into the acid by agitation with warm diluted alcohol.

Flückiger (1867) obtained in this way from 80 to 90 per cent. of the weight of the resin. By treatment with strong ammonia-water, passing through muslin, and decomposing the jelly-like mass with hydrochloric acid, Emmerling (1879) obtained it as a snow-white powder, and Kelbe (1889) in rather long triclinic prisms by crystallizing it from glacial acetic acid. Abietic acid melts, without losing weight, at 165° C. (329° F.) (Maly, Kelbe); other chemists observed lower melting-points. The acid is often in irregular, glassy, crystalline points or white scales, has in alcoholic solution an acid reaction, dissolves in ether, benzol, wood-spirit, chloroform, and carbon bisulphide, and yields with bases amorphous compounds. The *pinic* and *sylic* acid of Unverdorben (1825, etc.), Siewert (1859), and others are regarded by Maly as impure abietic acid, but it is not unlikely that, in addition to this one, other acids may be obtained from colophony of different origin.

Off. Prep.—Ceratum (Emplastrum) cantharidis, *U. S., Br.*; Cerat. extr. cantharidis, *U. S.*; Cerat. (Unguent.) resinæ, *U. S., Br.*; Charta epispastica, Empl. calefaciens, *Br.*; Empl. hydrargyri, *U. S.*; Empl. picis, *Br.*; Empl. resinæ, *U. S., Br.*; Empl. saponis, Unguentum terebinthinæ, *Br.*

Medical Action and Uses.—Resin is not prescribed internally. Sometimes, however, the fumes of boiling resin have been used to impregnate the air breathed by persons suffering from chronic *bronchial catarrh* unattended with fever. It is chiefly employed with essential oils to render plasters adhesive and stimulating.

RESINA COPAIBÆ, *U. S.*—RESIN OF COPAIBA.

Acidum copaibicum.—*Copaivic acid*, *E.*; *Résine de copahu*, *Acide copahutique*, *Fr.*; *Copaivaharz*, *Copaivasäure*, *G.*

Preparation.—The resin remains behind on evaporating copaiba or on distilling from it the volatile oil. (See *OLEUM COPAIBÆ*. For other processes of preparing the resin see page 505.)

Properties.—The resin is amorphous, of a yellowish or brownish-yellow color, brittle, of a slight odor of copaiba, and is soluble in alcohol, amyl alcohol, ether, benzol, volatile oils, and carbon disulphide. The alcoholic solution has an acid reaction and a somewhat bitter and acid taste. The resin is a mixture, and consists, according to the variety of copaiba used, of copaivic or metacopaivic acid, mixed with more or less of neutral resin. The crystallized copaivic acid of commerce is usually prepared from gurjun balsam (see page 505.)

Medical Action and Uses.—These have been sufficiently indicated under *COPAIBA*. Resin of copaiba has been administered in the *dose* of from 5 to 15 grains (*Gm.* 0.30–1.00), but more frequently in emulsion. One mode of preparing the latter is to take 3 ounces of the resin, softened by the addition of half its bulk of rectified spirit, and rub it down with 4 ounces of compound tragacanth powder (*Br. Ph.*) mixed with 4 pints of water. 1 ounce of this mixture contains 12 or 13 grains of the resin, and is given three times daily. Another formula is the following: Resin of copaiba 15 grains; compound powder of almonds 30 grains; water to fʒj.

RESINA DRACONIS.—DRAGON'S BLOOD.

Sang-dragon, *Fr.*; *Drachenblut*, *G.*

The resin obtained from the fruit of *Dæmonorops* (*Calamus, Willdenow*) *Draco*, *Blume*. *Nat. Ord.*—*Palmæ*.

Origin and Production.—This palm has a thin stem, which is sometimes 300 feet (90 M.) long, and climbs upon trees by means of strong spines situated on the petioles. Its small, globular-ovate, scaly fruits grow in dense panicles, and are covered with a resin which exudes and hardens upon their surface. By beating and shaking the fruit in a bag the resin breaks off, is mechanically separated from the fruit, softened in the sun or by boiling water, and formed into sticks or cakes. Subsequently the fruit is bruised, boiled with water, and an inferior resin collected in cakes. The palm is indigenous to Borneo and Sumatra, and grows in other of the East Indian islands.

Properties.—Dragon's blood is seen in commerce occasionally in the form of irregular grains, or more frequently in cakes or irregular masses, and in cylindrical sticks which are about 12 inches (30 Cm.) long and $\frac{1}{2}$ inch (12 Mm.) or more thick, and are wrapped in palm-leaves. It is of a dark red-brown color on the surface, of a brighter red, glossy, and somewhat porous internally, transparent in very thin splinters, and breaks with a

resinous but irregular fracture, caused by the fruit-seales and other impurities which are always present—in largest proportion usually in cake dragon's blood. Alcohol, amylie alcohol, benzol, and chloroform dissolve the resin readily, leaving the impurities behind; ether and oil of turpentine dissolve it less freely, and it is insoluble in petroleum benzin. It is inodorous, but when heated has a slight agreeable odor resembling that of benzoin; it is faintly sweetish, otherwise nearly tasteless, and when masticated becomes pulverulent.

Composition.—Dragon's blood contains a little fat, and is free from benzoic and cinnamic acid, as was shown by Hempel (1846). It consists of a peculiar resin, for which Johnston (1839) determined the formula $C_{20}H_{20}O_2$. By dry distillation Glénard and Boudault (1844) obtained a dark-red oil containing *dracyl* = toluol, C_7H_8 , and *draconyl* = styrol, C_8H_8 . Hlasiwetz and Barth (1865) obtained the following decomposition-products by fusing the resin with potassa: phloroglucin, a body giving a red reaction with iron salts, and paraoxybenzoic, protocatechuic, and benzoic acids—products which are likewise obtained by treating benzoin in the same manner.

Other Varieties.—On wounding the stem of *Pterocarpus Draco*, Linné, a papilionaceous tree of the West Indies, or the stem of *Dracaena Draco*, Linné, a liliaceous tree of the Canary Islands, exudations are obtained which resemble the dragon's blood described above. The dragon's blood of Socotra is the product of *Dracaena Ombet*, Kotschy, and is sent to Arabia under the name of *katin*. These varieties are rarely seen in our market.

Uses.—Dragon's blood is occasionally used as an addition to dentifrices, and was formerly an ingredient of several plasters. At present it is chiefly used for imparting a red color to spirit varnishes and for staining horn or wood; a *mahogany stain* is obtained by dissolving 1 part each of dragon's blood and aloes in 15 or 16 parts of alcohol.

Medical Action and Uses.—Dragon's blood, or sang-dragon, has little or no virtue besides its striking name. A certain degree of astringency probably led to its use in former times in diarrhœa, slight hæmorrhage, etc. It is occasionally used as an addition to dentifrices.

RESINA ELASTICA.—CAOUTCHOUC.

Gummi elasticum.—India-rubber, E.; Caoutchouc, Fr.; Kautschuk, Federharz, G.

Origin.—Caoutchouc exists in the milk-juice of a very large number of plants in the form of minute or larger granules, frequently associated with starch-granules, and kept in suspension by mucilage. Plants capable of yielding caoutchouc are found in all parts of the world, and belong mostly to the natural orders of Urticaceæ, Euphorbiaceæ, Apocynaceæ, and Asclepiadaceæ, but only species growing in the tropics yield the product in large quantity.

SIPHONIA (*Jatropha*, Linné *filius*) ELASTICA, Persoon, s. *Hevea guianensis*, Aublet (Euphorbiaceæ). This is a handsome tree about 60 feet (18 M.) high, with alternate trifoliate leaves, the leaflets being obovate, about 4 inches (10 Cm.) long, dark-green and glossy above and whitish-green beneath. It is a native of Guiana and Northern Brazil, and yields the Para rubber, which is regarded as one of the best varieties. Manihot Glaziovii, Müller, is the source of Ceara rubber; *Hancornia speciosa*, Gomez (Apocynaceæ), yields Mangabeira rubber. Similar products are obtained from *Hevea* (*Siphonia*, Kunth) *brasiliensis*, Müller, *Hevea discolor*, Müller, and other euphorbiaceous trees of Brazil, and in Central America from *Castilloa elastica*, Cervantes, Cast. *Markhamiana*, Collins (Artocarpeæ), and others.

FICUS (*Urostigma*, Miquel) ELASTICA, Roxburgh (Urticaceæ, Artocarpeæ). It is a handsome East Indian tree, and is not unfrequently seen here in hot-houses. It has large, leathery, oval, and entire leaves, which are dark-green and glossy above. *Ficus indica*, Linné, *F. religiosa*, Linné, and several other species also furnish caoutchouc which is considered inferior to that of the preceding and following species:

URCEOLA ELASTICA, Roxburgh (Apocynaceæ). It is a large climbing shrub indigenous to the Malayan Archipelago, and has opposite, ovate-oblong, and pointed leaves. Together with *Urceola* (*Chavanesia*, De Candolle) *esculenta*, Bentham, and other species, it yields Penang and Borneo caoutchouc, while Chittagong caoutchouc is prepared from *Willughbeia edulis*, Roxburgh, and allied Apocynaceæ.

Landolphia gunnifera, Lamarck (Apocynaceæ), of South-eastern Africa, *Landolphia florida*, Bentham, *Urostigma Vogelii*, Miquel (Artocarpeæ), and other plants of Western Africa, yield also caoutchouc.

Preparation.—In South America the white milk-juice, obtained from incisions made

through the bark, is dried upon clay moulds which are dipped into the liquid and suspended over a fire; the dipping is repeated until the layer of caoutchouc has the desired thickness, when it is removed from the mould. In India the juice is allowed to dry in masses or is formed into balls.

Description.—Occasionally the natural exudation is seen as a white or yellowish milk-like liquid, having a cream-like consistence and an unpleasant odor; it contains about 32 per cent. of caoutchouc. This is more generally met with either in the form of hollow clavate or bottle-shaped pieces, or in layers 2 or 3 inches (5 or 8 Cm.) thick, externally of a blackish or dark-brown color, and internally pale-brownish or whitish, and somewhat porous. In this condition it is tough and very elastic, the elasticity being increased at a somewhat elevated temperature, and considerably lessened near the freezing-point, though caoutchouc does not thereby become brittle. Its density varies between .92 and .96. When heated to 125° C. (257° F.) or a little higher caoutchouc melts, but on cooling remains soft and tar-like, and ultimately congeals to a brittle mass; heated to a still higher temperature, it is decomposed, and in the open air burns with a luminous sooty flame.

Caoutchouc is insoluble in water and in dilute acids and alkalies; it softens and swells when treated with hot alcohol or with amylie alcohol, and dissolves to a soft jelly-like mass in carbon bisulphide, stronger ether, oil of turpentine, and other hydrocarbons, notably in petroleum benzin and in the empyreumatic oils obtained on the destructive distillation of caoutchouc; it dissolves more readily and completely in chloroform, and may be melted together with fats and fixed oils. Rubber-tubing is apt to become brittle by use and on exposure—a change which Mareck (1881) found can be prevented by keeping the tubing under water, which is to be occasionally renewed: the outer layer of the rubber thereby assumes a fatty appearance, becomes lighter, then darker, and is improved for practical purposes. A strong solution of caoutchouc or an ammoniacal solution of shellac may be employed as a *cement* for fastening rubber upon other material.

When finely divided, mixed with sulphur, and afterward heated *vulcanized caoutchouc* is obtained: this, however, is more generally prepared by softening or dissolving caoutchouc and combining it with sulphur. Vulcanized rubber is insoluble in the ordinary solvents of caoutchouc, and its elasticity is not materially affected by a low temperature. Compounds of caoutchouc and sulphur, with which tar, white lead, chalk, or other substances have been incorporated, form *hard rubber* and *ebonite*, which at an elevated temperature may be moulded or rolled into sheets.

Composition.—Caoutchouc is a hydrocarbon, $C_{20}H_{32}$, and on destructive distillation yields *caoutchoucin*, which consists of two or more polymeric volatile oils, C_9H_8 .

Pharmaceutical Uses.—As an addition to plasters (see page 564).

Medical and Surgical Uses.—The utility of this substance in medicine depends chiefly upon its elasticity and impermeability to air and liquids, and, in the vulcanized condition, upon the numerous mechanical purposes which it subserves. Its elasticity, especially when woven into textile fabrics, adapts it to exert a modified pressure upon various parts of the body, limiting their enlargement and their movements, as in cases of *varicose veins*, *pendulous abdomen*, *hydrocele*, *varicocele*, *prolapsus ani*, *umbilical hernia*, etc. The same fabric and thin sheets of caoutchouc are very commonly used to protect bedding and clothing from the discharges of the sick, and, when worn next the skin, to prevent the exhalation of the perspiration, and thus keep the skin constantly moist or to restrain the evaporation of liquids applied to it. In this manner caoutchouc has been extensively used in treating *eczema* and *psoriasis* and various cutaneous diseases, as well as *burns*, *ulcers*, and other analogous lesions, and in protecting parts liable to *neuralgia* or *rheumatism* from the influence of vicissitudes of weather. It is unnecessary to enumerate the various surgical instruments constructed with this material in its more or less flexible and elastic and its hard or vulcanized condition—the bougies, catheters, pessaries, nipple-shields, specula, syringes, stomach, rectal, drainage, and other tubes, and countless instruments which combine lightness, firmness, durability, insusceptibility to corrosion, and at the same time cheapness, in a degree unequalled by any metal. A similar statement might be made of numerous articles of surgical apparatus, orthopædic and others, including artificial ears, noses, hands, etc. Caoutchouc can scarcely be used for any strictly medicinal purpose; even the application of it dissolved in chloroform to prevent the development of small-pox pustules is really mechanical in its action, and, moreover, is less efficient than it was claimed to be.

RESINA JALAPÆ, U. S., P. G.—RESIN OF JALAP.

Jalapæ resina, Br.—*Résine de jalap*, Fr.: *Jalapenharz*, G.

Preparation.—Jalap, in No. 60 powder, 100 parts (20 oz. av.); Alcohol, Water, each a sufficient quantity. Moisten the powder with 25 parts (5 oz. av. or $5\frac{1}{8}$ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until 200 parts (40 oz. av. or about $2\frac{3}{4}$ pints) of tincture are obtained, or until the tincture ceases to produce more than a slight turbidity when dropped into water. Distil off the alcohol by means of a water-bath until the tincture is reduced to 40 parts (8 oz. av.), and add the latter, with constant stirring, to 900 parts (180 oz. av. or $10\frac{3}{4}$ pints) of water. When the precipitate has subsided decant the supernatant liquid, and wash the precipitate twice, by decantation, with fresh portions of water. Place it upon a strainer, and, having pressed out the liquid, dry the resin with a gentle heat.—*U. S.*

With slight modifications these directions are the same as in the former Pharmacopœia. The alcoholic tincture of the jalap containing the resin in solution is concentrated by distillation, and this liquid while still warm poured into water, stirring continually, so as to bring nearly all particles of the resinous matter in direct contact with water, whereby the solutions of those constituents which are soluble in water is facilitated. After repeated washings with fresh portions of water the resin is collected and dried. By this treatment water removes sugar and some other principles of jalap, which are also soluble in water, and which possess some medicinal activity (see p. 643).

The British Pharmacopœia directs 1 part of water for 2 parts of jalap to be added to the percolate, from which nearly the whole of the alcohol may be recovered by distillation. The residue while hot is poured into an open dish and allowed to cool, when the liquid portion is decanted, the resin washed several times with hot water, and dried.

The German Pharmacopœia directs the jalap to be exhausted by digestion with alcohol, the tincture to be concentrated, and the resinous residue to be repeatedly washed with warm water as long as this takes up coloring matter. The resin may also be obtained by depriving jalap of its principles soluble in hot water, drying and powdering the residue, and exhausting it with alcohol. Good jalap yields about 15 per cent. of resin (not less than 12 per cent. *U. S.*).

Properties.—Resin of jalap is in yellowish-brown or brown masses or fragments, which break with a glossy resinous fracture and are translucent on the edges. By repeated solution in a little alcohol and precipitation with water it may be obtained nearly white. It is very brittle, and readily reduced to powder, varying in color between yellowish- and light-brown; it has a slight sweetish odor and a somewhat acrid taste, and is entirely soluble in alcohol, and insoluble in carbon disulphide and oil of turpentine. Ether dissolves only a small portion of it, amounting to between 5 and 10 or sometimes 12 per cent., as ascertained by C. D. Farwell (1878); on the evaporation of the ethereal solution a soft resinous mass is left, which may be dissolved in potassa solution, forming a reddish-brown liquid, and is precipitated again on the addition of an acid. The resin, which is insoluble in ether, is the *convolvulin* of W. Mayer, and is soluble in potassa solution, but not precipitated on the addition of an acid. (The chemical nature of this resin and its relation to allied resins have been explained on pp. 846, 847.)

Tests.—Resin of jalap should diminish but little or not at all in weight on being exposed for some time to the heat of a water-bath (absence of water). On being triturated with water it should lose nothing in weight, and the liquid should not become colored, showing that it has been well washed with water. To ether and to potassa solution it should have the behavior described above. Adulterations with other resins are proved by the amount soluble in ether, which should not exceed 10 per cent., or, if they are insoluble in ether, by the precipitate occasioned with acids in the potassa solution. The presence of guaiacum resin is indicated by a green or blue color produced with strong nitric acid or with tincture of chloride of iron. An adulteration with rosin may be detected by the solubility in oil of turpentine, and the presence of aloes manifests itself by its bitter taste and the production of picric acid when treated with nitric acid. "1 part of resin of jalap should dissolve in 5 parts (50 parts, *U. S.*) of warm ammonia-water; on cooling, the solution should not gelatinize (absence of colophony), and should remain clear after being supersaturated with an acid."—*U. S., P. G.* The last part of this test is correct only for that portion of jalap resin which is insoluble in ether; but

the pharmacopœial resin, though completely soluble in about 8 parts of ammonia-water, yields with acids a precipitate which is again soluble in ammonia. The ammoniacal solution of the resin, when carefully evaporated to dryness at a moderate heat, leaves a residue which is soluble in water.

Pharmaceutical Preparations.—SAPO JALAPINUS, *P. G.* 4 parts each of resin of jalap and medicinal (white Castile) soap are dissolved in 8 parts of alcohol spec. grav. .894, and the solution evaporated with constant stirring to the consistence of a pill mass weighing 9 parts. This preparation is of a brown-yellow color, is soluble in alcohol, and yields with about 10 parts of water a nearly clear solution, which becomes somewhat cloudy, but does not separate any resin.

PILULÆ JALAPÆ, *P. G.* Mix jalap soap 3 parts and powdered jalap-root 1 part. Each pill is to weigh 0.10 Gm. and to be dusted with lycopodium.

TINCTURA RESINÆ JALAPÆ. Jalap resin 1 part, alcohol 10 parts.—*P. G.* 1872.

Off. Prep.—Pilula scammonii comp., *Br.*

Medical Action and Uses.—This preparation contains all or nearly all the purgative elements of jalap, and may be prescribed for the same purposes in doses of from 3 to 6 grains (Gm. 0.15–0.30), or, combined with other purgatives, in even smaller doses. A valuable formula is the following: $\mathcal{R}$. Resinæ jalapæ gr. xxx; Pulv. lycopodii gr. x; Saponis medicinal. gr. xc; Amygd. dule. excort. gr. cxx.—*M. S. A.* Divide into 120 pills. Two of these pills produce one copious stool, and seven or eight pills as many liquid evacuations.

RESINA PODOPHYLLI, *U. S.*—RESIN OF PODOPHYLLUM.

Podophylli resina, *Br.*; *Podophyllum*, *P. G.*—*Resin of May-apple*, *E.*; *Résine de podophylle*, *Fr.*; *Podophyllumharz*, *G.*

Preparation.—Podophyllum, in No. 60 powder, 100 parts (20 oz. av.); Hydrochloric Acid 1 part (88 grains or 78 minims); Alcohol, Water, each a sufficient quantity. Moisten the powder with 40 parts (8 oz. av. or 9½ fluidounces) of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until 150 parts (30 oz. av. or about 2 pints) of tincture are obtained, or until the tincture ceases to produce more than a slight turbidity when dropped into water. Distil off the alcohol by means of a water-bath until the tincture is reduced to the consistence of honey, and pour it slowly, with constant stirring, into 100 parts (20 oz. av. or 19½ fluidounces) of water, previously cooled to a temperature below 10° C. (50° F.), and mixed with the hydrochloric acid. When the precipitate has subsided decant the supernatant liquid, and wash the precipitate twice, by decantation, with fresh portions of cold water. Spread it in a thin layer upon a strainer, and dry the resin by exposure to the air in a cool place.—*U. S.*

This process differs from that of the *U. S. P.* 1870 mainly in this, that the tincture is more concentrated by distilling off nearly the whole of the alcohol, that this residue is precipitated by cold water, and that the precipitate is dried in a cool place. The low temperature directed in the precipitation and drying is also the chief distinction from the process of the British Pharmacopœia, which permits the resin to be dried on a stove.

On pouring the concentrated tincture of podophyllum into acidulated water the extractive matters remain in solution while the resin is precipitated. The addition of hydrochloric acid appears to exert no action on the product, and to be useful merely in hastening the deposition of the resin from the aqueous liquid. Both the British and French Pharmacopœias omit the hydrochloric acid. The yield is between 4 and 5 per cent. of the weight of podophyllum used; by exhausting the rhizome with alcohol of specific gravity .930, *G. H. C. Klie* (1877) claimed to have obtained as much as 7½ per cent.

Properties.—The color of resin of podophyllum, when pure, is grayish-white, with a slight tinge of yellow. To obtain it of this shade it is necessary that the resin be precipitated in the cold and dried at a temperature not exceeding 35° C. (95° F.). If a higher heat is used it turns darker, and finally deep-brown. If precipitated in the presence of alum or other earth salt, the resin is of a more decided yellow color. It dissolves to a limited extent in carbon disulphide; from 15 to 20 per cent. of it is soluble in ether, and about 80 per cent. is dissolved by boiling water and reprecipitated on cooling; a small portion of the resin, however, remains in solution in the water, and this solution

has a bitter taste, acquires a brown color on the addition of ferric chloride, and becomes opalescent and yellow with basic lead acetate, the mixtures gradually separating orange-red floccules. Alkaline liquids dissolve the resin readily, yielding deep-yellow, afterward brown-yellow, solutions, and deposit nearly the whole of it on being supersaturated with an acid. According to Power, podophyllum resin becomes soft at 120° C. (248° F.), and is completely melted at 124° C. (255° F.). Sulphuric acid colors it intensely yellow, the color changing to purplish and to brown on the addition of a trace of nitric acid. Among the oxidation-products by nitric acid are oxalic acid and an amorphous yellow substance.

Composition.—F. B. Power (1877) observed that the largest portion of the resin yields yellow and orange-yellow precipitates with acetate and subacetate of lead from an alcoholic solution, and after removing the lead an acid resin, which may be called *podophyllinic acid*, is obtained, to which the color reactions described above are due. Its alcoholic solution is colored dull-green by ferric chloride, and its aqueous solution reduces cupric oxide in alkaline solution. Fused with potassa, it yields *protocatechuic acid*, but no resorcin. As it is only partly soluble in ether, it consists probably of two acids. The *neutral resin*, which is not precipitated by lead, shows none of the above characteristics, but is likewise separable into one portion soluble and one portion insoluble in ether. The officinal resin contains also a little fatty matter, and yields a small proportion of ash, consisting chiefly of sodium and potassium salts. Podwissotzki (1880) obtained from podophyllum resin yellow needles resembling quercetin, a green oil, a crystalline fat acid, podophyllinic acid (without activity, soluble in hot water), and two poisonous principles: one of these, *podophyllotoxin*, is white, crystallizable, very bitter, faintly acid, sparingly soluble in water, freely soluble in alcohol, and by treatment with ammonia yields podophyllinic acid and *picropodophyllin*. The latter is intensely bitter, crystallizable, nearly insoluble in water, soluble in alcohol, and freely soluble in chloroform, ether, and acetic ether.

Medical Action and Uses.—The medicinal properties of this preparation have been sufficiently set forth elsewhere. (See *PODOPHYLLUM*.) Its action and uses closely resemble those of the resin of jalap. The following formula is convenient for the relief of habitual constipation: ℞. Resin. podophylli. Ext. belladon. āā gr. iv ad gr. vj; Ext. nucis vomicæ alcoholic gr. viij. M. et in pil. No. xij divid. S. One after dinner.

RESINA SCAMMONII, U. S.—RESIN OF SCAMMONY.

Scammonix resina, Br.—*Résine de scammonée*, Fr.; *Scammoniaharz*, G.

Preparation.—Take of Scammony, in No. 60 powder, 100 parts (4 oz. av.); Alcohol. Water, each a sufficient quantity. Digest the scammony with successive portions of boiling alcohol until exhausted. Mix the tinctures, and reduce the mixture to a syrupy consistence by distilling off the alcohol. Then add the residue to 250 parts (10 oz. av. or 9½ fluidounces) of water, separate the precipitate formed, wash it thoroughly with water, and dry it with a gentle heat.—U. S.

Take of scammony-root, in coarse powder, 8 ounces; rectified spirit a sufficiency; distilled water a sufficiency. Digest the scammony-root with 16 fluidounces of the spirit in a covered vessel at a gentle heat for 24 hours; then transfer to a percolator, and when the tincture ceases to pass add more spirit, and let it percolate slowly until the root is exhausted. Add to the tincture 4 fluidounces of the water, and distil off the spirit by a water-bath. Remove the residue while hot to an open dish, and allow it to become cold. Pour off the supernatant fluid from the resin, wash this several times with hot water, and dry it on a porcelain plate with the heat of a stove or water-bath.—Br.

Prof. Markoe (1877) showed that the alcoholic extract of scammony yields to water only 2 per cent. of soluble matter, which is removed by washing, as directed in the first formula. The French Codex directs the alcoholic solution to be treated with animal charcoal for the purpose of removing most of the coloring matter. The yield of resin varies with the quality of scammony employed. The British Pharmacopœia permits the resin to be prepared from scammony or from scammony-root by washing the alcoholic extract with hot water; the root yields 5 to 5½ per cent. of resin.

Properties.—Scammony resin is of a brownish color, or yellowish after treatment with animal charcoal. It is brittle, of a resinous, glossy fracture, translucent on the edges, and nearly tasteless, but has a slight sweetish odor, which is stronger and peculiar, somewhat like leather, when prepared from the root. It differs from scammony in not forming an emulsion with water, and in being completely soluble in oil of turpentine

and in ether. It dissolves in alcohol, ammonia-water, and warm potassa solution, and when this alkaline liquid is supersaturated with an acid it remains transparent and does not produce a precipitate. The resin softens at about 120° C. (248° F.) and fuses near 150° C. (302° F.).

Tests.—The behavior to solvents, as described, distinguishes scammony resin from most other resins. If adulterated with guaiacum, its alcoholic solution would render the fresh-cut surface of a potato blue, and it would acquire a green or blue color on the addition of chlorine-water or ferric chloride.

Constituents.—Except the coloring principle, scammony resin consists wholly of *scammonin*, which in its pure state is white, inodorous, and tasteless. F. Keller (1857) ascertained it to be the anhydride of *scammonic acid*, which is soluble in water, and on being boiled with dilute acids is converted into sugar and *scammonolic acid*. According to Spirgatis (1860), these compounds have the same composition, and are identical with jalapin, jalapic acid, and jalapinolic acid (see page 847).

Off. Prep.—Extr. colocynth. comp., U. S.; Br.; Mistura scammonii, Pil. scammonii comp., Br.

Medical Action and Uses.—The action of resin of scammony does not differ in kind, but only in degree, from that of scammony itself, but the resin is about twice as strong as scammony. In the dose of about 8 grains (Gm. 0.50) it occasions colic and watery stools, very much as jalap does, but is more apt than the latter to excite rectal irritation. Being nearly insipid, it may conveniently be given to children. It is seldom used alone, but is frequently associated with calomel, jalap, etc. in cases of *constipation* and abdominal *dropsy*, and also as a vermifuge for *lumbricoid ascarides*.

It may be prescribed in doses of from 5 to 15 grains (Gm. 0.30–1), and should be made into an emulsion with milk, almonds, mucilage, or other demulcent, and sweetened. The following formula is convenient: ℞. Resin. scammon. gr. viij; rub with Sacch. alb. gr. xlv; mix gradually with Lact. vaccin. fʒiv; Aq. laurocerasi fʒj. M. S. One or two tablespoonfuls every hour.

RESORCINUM.—RESORCIN.

Resorcinol, E.; *Résorcine*, Fr.; *Resorcin*, G.

Formula $C_6H_4(HO)_2$. Molecular weight 110.

Origin.—Resorcin was discovered by Illasiwetz and Barth (1864) on melting galbanum, ammoniac, or guaiacum resin with potassa. It is produced in a similar manner from asafetida, sagapenum, ascaroid resin, and from phenol-sulphonic acid and other derivatives of phenol; likewise on the dry distillation of extract of Brazil-wood.

Preparation.—The alcoholic extract of ammoniac or galbanum is carefully fused with three times its weight of potassa until the mass has become homogeneous, when it is dissolved in water, the solution slightly acidulated with sulphuric acid, filtered, and agitated with ether. On evaporating the ether, impure resorcin is left; the volatile fatty acids present are combined with baryta, and the resorcin is dissolved by ether and further purified by distillation and recrystallization.

A cheaper process starts with benzol, which by strong sulphuric acid is first converted into benzol-disulphonic acid; on melting the potassium salt of this acid with potassa it is decomposed into potassium sulphite and resorcin.

Properties.—Resorcin crystallizes in colorless, short, rhombic prisms or plates, which are neutral to test-paper, inodorous, and have a unpleasantly sweet and somewhat acid taste. It melts at 118° C. (244.4° F.) and boils at 276.5° C. (530° F.). On exposure to air it becomes reddish. It is freely soluble in water (in 14 parts), in alcohol and ether, less freely soluble in chloroform, carbon disulphide, and benzol, and requires about 20 parts of fixed oil for solution. It burns with a bright flame, without leaving any residue. Its solution is transiently colored violet by chlorinated lime; with ferric chloride it becomes purplish-black, the color disappearing by ammonia; with copper sulphate and ammonia the solution turns black. Resorcin precipitates metallic silver from ammoniacal solution of silver nitrate. Its solution in ammonia when exposed to the air turns rose-red and brown, and, when heated, green and blue, this color being changed to red by acids. The aqueous solution of resorcin yields with bromine-water needles of tribrom-resorcin, $C_6Br_3H_3O_2$.

Tests.—When carefully heated in a test-tube, resorcin should melt to a clear colorless liquid; on increasing the heat it should volatilize, producing white vapors, and leaving

no residue or merely a minute amount of charcoal. Heated in a porcelain or platinum dish, it should volatilize without residue.

Physiological Action.—In 1880, Andeer described the severe toxical phenomena occasioned by resorcin in animals, and concluded that it acts primarily upon the spinal and then upon the cerebral nervous centres. It stimulates and then paralyzes these organs, and occasions somnolence and collapse (*Eindeutende Studien über das Resorcin*). Afterward the experiments of Dujardin-Beaumetz and Callias (*Bull. de thérap.*, ci. 13) showed that when given to animals resorcin occasions tremor, and then epileptiform convulsions, which come on and also subside rapidly; that it does not seem at first to impair consciousness or general sensibility; and that recovery from its effects is rapid. Fatal doses excite violent and prolonged convulsions; the eyes are fixed and insensible to light and the pupils dilated; general sensibility is obtunded and afterward destroyed; spasm of the diaphragm occurs; the chest is rigidly contracted, the breathing hurried and shallow; the heart beats rapidly and feebly, and the capillaries become distended; respiration is suspended before the heart's pulsation in the act of death. Among the symptoms is neither vomiting, purging, nor urination. According to Dujardin-Beaumetz and Callias, during the spasms the temperature of the animal is raised to 104° or 105° F., but Andeer states that at the point of death it may fall to 86° F. After the animal's death, according to Andeer, no characteristic lesions are found in the nervous system; but other experimenters state that the cerebro-spinal centres are intensely congested, especially at their upper portion. It is agreed by all that the lungs and the right side of the heart are distended with blood; the coagula are described as dark, with light stripes, and containing uric acid. No definite change is met with in the corpuscles. Resorcin is excreted with the urine, rendering it dark or almost black.

In the course of 2 hours Andeer took about 150 grains (Gm. 10) of resorcin dissolved in a quart of water. He was found fast asleep, but had no recollection of how he fell asleep. Subsequently, he took the same quantity of the drug dissolved in a pint of water in the space of a quarter of an hour. He perceived flashes before his eyes, his sight grew dim, his eyelids heavy; his hearing and smell were completely obtunded; his mouth was pasty, and his tongue thick. He fell to the floor bathed in a cold sweat, and his feet also were cold. Then convulsions came on, respiration grew panting and sighing, and later spasmodic flexion of the limbs occurred, with opisthotonos. After five hours of treatment consciousness returned, but no memory of the attack remained. On the following day restoration to health was complete. Dr. Murrell relates (*Times and Gaz.*, Oct. 1881, p. 486) the case of a woman who took 120 grains of resorcin, and almost immediately became giddy, and then insensible. She was pale and cold, drenched in sweat; the pupils were equal, and the pulse and chest movements almost imperceptible; the limbs were relaxed; there was no reflex action and no spasm; the axillary temperature was 95° F. Recovery took place within 24 hours. The first urine she passed presented an olive-green color. The occurrence of convulsions in the one case and their absence in the other case deserve notice.

Resorcin has the power of retarding or preventing fermentation and putrefaction. A solution of 1 per cent., it is said, will maintain the acidity of normal urine for a month (Andeer). But, according to Platt, the antiseptic power of resorcin is greatly inferior to that of carbolic acid (*Amer. Jour. of Med. Sci.*, Jan. 1883, p. 89). Nevertheless, it is certain that a solution of the strength just mentioned has preserved from decomposition such substances as pancreas, blood, and urine, and arrested commencing putrefaction in them. Andeer claims not only that it is equal to carbolic and pyrogallie acids in antiseptic virtues, but that it has over them the great advantage of not acting poisonously when locally applied, and also of not attacking metallic instruments. It promotes healing by the first intention of punctured or incised wounds, and when applied to artificially-infected wounds of the cornea, conjunctiva, gums, etc. it destroys micro-organisms and promotes the healing of such wounds. A 1 or 2 per cent. solution does not irritate the integuments nor cause any eruption. It is as well tolerated as any other antiseptic by the respiratory tract.

Medical Uses.—According to Lichtheim (*Monthly Abst.*, Dec. 1880, p. 120; *Bull. de thérap.*, ci. 139), if from 30 to 45 grains of this substance are given to a patient in high fever, almost immediately a sort of intoxicated excitement takes place, either wild or muttering, with tremor of the hands. It, however, is transient, and is followed by profuse diaphoresis, with subsidence of the pulse and temperature. It is said to produce such effects more quickly than salicylic acid or quinine, but that their duration is brief. It is not claimed that this medicine shortens the duration of idiopathic fever or of serious

inflammations; and one is therefore at a loss to conjecture why the sick should be made the subjects of physiological experiments with it. In typhoid fever it has been used without advantage (Dujardin-Beaumetz, *loc. cit.*), and Brieger judged it similarly in this as well as in inflammatory diseases (*Zeitschrift f. klin. Med.*, v. 146). The former of these tested it in acute articular rheumatism, and found that it was not comparable with salicylic preparations. The statements made of its efficacy in puerperal and periodical fevers and erysipelas have not been confirmed. Some laud it in all the various forms of functional gastric disease, which seem to be more common in Germany than elsewhere (catarrh, dilatation, etc.), while Andeer does not so much depend upon it to check gastric fermentation as to promote the healing of abrasions and ulcers of the mucous membrane of the stomach, and to moderate the destructive process in cancer of that organ (*Zeitschrift f. klin. Med.*, ii. 297). It has been used with more or less advantage to deodorize and disinfect fetid stools.

Topically, however, resorcin is more distinctly useful. A solution of the strength of from 1 to 3 per cent. has been found efficient in moderating mucous *profluvia* from the nostrils, ears, vagina, urethra, etc., and in removing their fetor. It has been found efficient in chronic purulent *otitis* of the middle ear when applied pure or mixed with 7 parts of boric acid. In gonorrhæa Brieger used a 5 per cent. solution. It was very painful, and did not cure the complaint, probably because the solution was needlessly strong. A 1 per cent. solution has been applied to the interior of the larynx with alleged advantage in *whooping cough*. Andeer highly commends the caustic treatment of *chancres* by means of crystals of resorcin or a saturated ethereal solution of them. Favorable reports are also furnished by Leblond, Fissiaux, and Bombin (*Med. News*, xlii. 384; xliii. 266). *Papilloma* and other outgrowths of the mucous membrane have been destroyed by this caustic, which Andeer declares to be sure and painless. In a case of *carbunculous boils* occupying a large part of the arm a rapid cure followed the application of a thick layer of "resorcin ointment and vaseline in equal parts" (*Bull. de therap.*, cix. 325). *Myomas* of the eye and larynx are said to have been cured by resorcin. It is even claimed that in crystals or in powder it displays its greatest virtue in the *diphtheria* of wounds, and especially of the mouth and pharynx. "In one week, at the latest," says Andeer, "the severest form of this disease is wholly cured, and without any evil consequences." This statement has received no confirmation, nor probably will it be found correct, for diphtheria is not a local disease.

Administration.—Resorcin may be given internally in *doses* of from 1 to 4 grains (Gm. 0.06–0.25), and gradually increased to five or even ten times that quantity. It is best administered in syrup or emulsion. For atomized inhalation and for injecting cavities a solution of $\frac{1}{2}$ to 1 per cent. may be used; but in phagedæna, syphilis, etc. a saturated solution or the crystals may be employed. In erythematous and erysipelatous complications a resorcin-vaseline ointment may be applied.

RHAMNI SUCCUS.—BUCKTHORN-JUICE.

Suc de nerprun, Fr.; *Kreuzdornbeerensaft*, G.

The recently-expressed juice of the ripe berries of common buckthorn, *Rhamnus catharticus*, Linné, s. *Cervispina cathartica*, Moench. Bentley and Trimen, *Med. Plants*, 64. *Nat. Ord.*—*Rhamnaceæ*.

Origin and Description.—The buckthorn is a branching shrub about 9 feet (2.7 M.) high; it grows in thickets throughout the greater part of Europe and in Siberia, and is naturalized to some extent and cultivated for hedges in North America. It has ovate, minutely serrate, and frequently fasciculate leaves, small, yellowish-green, dioecious flowers in umbellate clusters, and black, glossy, globular four-celled drupes about $\frac{1}{4}$ inch (8 Mm.) in diameter, surrounded at the base by a portion of the persistent calyx, and containing four hard, dark-brown, deeply-grooved seeds enclosed in a parchment-like shell. The dried fruit is deeply and somewhat reticulately wrinkled from the shrinking of the sarcocarp. It is recognized by European pharmacopœias as *Fructus rhamni cathartici*, s. *Baccæ spinæ cervinæ*, P. G. In the fresh state it contains a greenish or purplish-green sarcocarp, and yields by expression a greenish-colored juice having an unpleasant odor, and a disagreeable, bitter, and rather acrid taste. The color changes on keeping to reddish- or purplish-brown, becomes red on the addition of an acid, and greenish-yellow when rendered alkaline.

Composition.—The various analyses of buckthorn-berries have furnished the cathartic principle *rhamnocathartin* in the form of an amorphous, translucent, yellowish, brittle

mass, which Binswanger (1849) and Winckler did not succeed in crystallizing. This has the taste of the berries, is fusible, dissolves in water and alcohol, is insoluble in ether, is not destroyed during the fermentation of the juice, and yields picric acid when oxidized with nitric acid. The juice contains also a peculiar variety of tannin, sugar, gum, and *rhamnin*, which crystallizes in yellowish neutral and inodorous granules or needles, has little taste, dissolves in cold water and alcohol, and is insoluble or nearly so in ether, chloroform, benzol, and carbon disulphide. Its composition is still unknown, the analyses of different chemists having given conflicting results. Its solution is rendered olive-green by ferric chloride, and deep-green, or with an excess red-brown, by chlorinated lime. Dilute acids split it readily into a non-fermentible sweetish sugar, a gummy substance, and *rhamnetin*. This crystallizes readily from phenol in golden-yellow scales, is sparingly soluble in water, somewhat more soluble in alcohol and ether, and is colored green-brown or black by iron salt.

Allied Drugs.—*Rhamnus infectoria*, *Linne*.—French berries, *E.*; Graines d'Avignon, *Fr.*; Gelbbeeren, *G.*—The shrub grows in Southern Europe, and the berries resemble buckthorn-berries in size and appearance, but are of a brownish or greenish-brown color, and are usually two- or three-furrowed.

Rhamnus amygdalina, *Desfontaines*, *Rh. saxatilis*, *Linne*, and probably other species growing in Western Asia, South-eastern Europe, and Northern Africa, yield the so-called *Persian berries*. They resemble the preceding, but are of a more greenish and internally yellowish color, and contain pale-brown seeds having a broad furrow. These and French berries contain one or more yellow coloring principles, the principal one being probably *xanthorhamnin*, $C_{48}H_{66}O_{29}$, which, according to Liebermann (1878), is split by acids into isodulcit (see *QUERCUS TINCTORIA*) and rhamnetin, $C_{12}H_{10}O_5$. (See also FRANGULA, p. 711.)

SAP-GREEN is prepared from unripe buckthorn-berries by bruising and fermenting them, expressing the juice, adding alum and potash, and evaporating.

Off. Prep.—Syrupus rhamni, *Br.*, 1867.

Medical Uses.—This preparation is employed in making the syrup of buckthorn.

RHEUM, U. S.—RHUBARB.

Rhei radix, *Br.*; *Radix rhei*, *P. G.*—*Rhubarb-root*, *E.*; *Rhubarbe*, *Fr.*; *Rhubarber*, *G.*

The root of *Rheum officinale*, *Baillon*, and of other species of *Rheum*, from China, Chinese Tartary, and Thibet. Bentley and Trimen, *Med. Plants*, 213, 214, 215.

Nat. Ord.—Polygonaceæ.

Origin.—That rhubarb-root is obtained from the western and north-western provinces of China and from other parts of the highlands of Central Asia has been known for a long time. The efforts made by the Russian government since the first half of the eighteenth century to obtain the rhubarb-plant have been unsuccessful; at least the plants *Rheum palmatum* and *Rh. undulatum*, *Linne*, raised in Europe from the seeds thus procured, had roots which were not identical with true rhubarb. More recently, however, several species have become known in Europe which appear to be the source of most, if not all, rhubarb.

RHEUM OFFICINALE, *Baillon*. In 1867, Dabry, French consul at Shanghai, procured from South-eastern Thibet a number of fresh root-stocks, which were sent to Paris, where they arrived in a completely decayed condition, a few buds excepted. From these plants were successfully raised, of which one flowered in 1872 and was described by Baillon under the above name. It has a stout rhizome with few roots, and produces a tall stem, from near the thick base of which numerous orbicular-ovate, five- or seven-lobed leaves grow, attaining sometimes a length of blade equal to 4 feet (1.2 M.). The inflorescence is large, much branched, racemose, with numerous clustered and drooping, small greenish-white flowers, and with pendulous, triangular, yellow fruits, nearly $\frac{1}{2}$ inch (12 Mm.) long, and with a bright crimson wing on each angle.

RHEUM PALMATUM, *Linne*. From the observations made by Lieutenant-Colonel Przewalsky during his travels (1872-73) in Central Asia, it appears that a variety of this species, which he collected near Lake Kokonor, in North-western China, was really the source of the formerly highly esteemed Russian rhubarb. Maximowicz (1874) described this variety as *Tonguticum*, and contended that its cultivation in Europe was unsuccessful on account of the principal roots decaying. Dragendorff (1877), however, compared the roots to English rhubarb in appearance. The plant grows to the height of 8 or 10 feet (2.4 to 3 M.), has large orbicular-ovate, deeply five-lobed and cut radical leaves, numerous small pale pinkish flowers, and drooping, triangular fruits, with a dull red wing on each

angle. Przewalsky (1881) observed another very tall rhubarb, the root of which weighed 26 pounds.

RHEUM HYBRIDUM, *Murray*, is chiefly characterized by the nearly flat and wrinkled leaves, which are heart-shaped at the base, pointed above, and undulately lobed on the margin. A variety of this species, named *Colinianum*, was received by Prof. Baillon (1878) from M. Colin of Verdun, who had procured it from Central Asia; its root has the characters of rhubarb.

Production.—From the meagre accounts concerning the collection of the root and its preparation for the market, it appears that the root is dug up in autumn, deprived of its corky layer, cut into sections to facilitate the drying, and afterward exposed to the air, frequently strung on a cord, and, if necessary, dried by the aid of artificial heat. In the Chinese ports it is assorted according to its shape.

Rhubarb enters commerce now chiefly from Shanghai and other ports of Northern China, and is hence known as *Chinese rhubarb*; much of it was and is still first shipped to India before it is sent to Europe; the so-called *East India rhubarb* is therefore not distinct from the Chinese. Formerly an excellent quality of rhubarb was received through Siberia under treaty stipulations between the governments of Russia and China. This was almost exclusively received at Kiachta, and there subjected to a very stringent examination, carefully trimmed and dried, and afterward packed in waterproof chests and sent overland to Moscow and St. Petersburg. This variety was known as *Russian* or *crown rhubarb*. However, since about the year 1850 various causes have operated against the rhubarb trade through Siberia; from 1860 very little rhubarb was received at Kiachta, and the office for the inspection of this drug was finally abolished in 1863.

For the eight years ending June, 1883, the average annual importation of rhubarb into the United States was 92,716 pounds; in 1880–81 it was 163,519 pounds.

Description.—Rhubarb, as met with in commerce, consists of segments of the rhizome, which are usually assorted into *round* and *flat*, the one kind being either subcylindrical or conical, while the other is irregularly trapezoidal in outline and flattish or convex on one side. They are often perforated with a hole, in which remnants of the cord are found by which the root was suspended in drying. The outer surface is always trimmed, but patches of the corky layer, or at least of the inner portion thereof, are usually present to a small extent, and are of a dark blackish-brown color. Otherwise, the outer surface is nearly smooth or somewhat wrinkled, and after the removal of the adhering yellowish dust shows numerous brown-yellow or red-brown short striae imbedded in a white tissue, in which an arrangement into elongated meshes is observable. The transverse surface has a marbled appearance, and consists of white parenchyma traversed by innumerable fine reddish medullary rays; these, in the centre of the pieces, are very irregular, curved, and interrupted, and show a more regular radiating arrangement only toward the circumference near the dark-colored cambium-line and in the inner bark, which is generally present in Chinese rhubarb. In Russian rhubarb the cambial zone was

FIG. 235.

Russian Rhubarb: transverse section.

FIG. 236.

Chinese Rhubarb: transverse section.

entirely trimmed off, leaving only a narrow zone of regularly radiating nearly parallel medullary rays. Near this zone a dense circle of stellate spots was seen, consisting of small groups of medullary rays, each group radiating usually in curved lines from a common centre. These stellate spots are likewise observed in Chinese rhubarb, though not in all pieces, and are in most cases less numerous; they indicate the origin of the radical leaves, and must therefore be necessarily most numerous in old rhizomes. Rhubarb is hard, compact, and breaks with an uneven granular, not at all fibrous, fracture; it has a peculiar aromatic odor, a bitter and somewhat astringent taste, and when masticated is gritty between the teeth and imparts a yellow color to the saliva. The grittiness of rhubarb is due to the parenchyma containing aggregated tufts of microscopic crystals

of calcium oxalate, the composition of which was already ascertained by Scheele (1784). Pieces which are spongy, decayed, worm-eaten, or mouldy should be rejected. Unsightly pieces are sometimes artificially improved in appearance by means of powdered turmeric, in which case the surface turns red-brown with a solution of boric acid.

Constituents.—Rhubarb has been frequently subjected to analysis, and various

FIG. 237.

Rhubarb: section through and near cambium, magnified 40 diameters.

more or less active substances were separated from it, and by the different investigators named *rhein*, *rhabarbarin*, *rheumin*, and *rhabarbaric acid*. In 1835, Peretti isolated from it a crystalline, yellow, sublimable principle which dissolves in potassa with a red color. This was subsequently proven by Schlossberger and Döpping (1844) to be identical with *chrysophanic acid*, $C_{15}H_{10}O_4$ (Liebermann, 1875). It was first obtained in a resinous condition by Schrader (1819) from a common lichen, *Parmelia parietina*, *Linne*, was obtained pure by Rochleder and Heldt (1843),

FIG. 238.

Oxalate of Calcium Crystals in Rhubarb.

and afterward found in the roots of *Rumex* and of cultivated rhubarb. The precipitate occurring in tincture of rhubarb yields chrysophanic acid on treating it with benzol. Or rhubarb may be exhausted with cold water, and the residue, after drying, with benzol; on concentrating the benzol solution chrysophanic acid crystallizes on cooling (Schlossberger). It crystallizes in bright-yellow needles or plates, is inodorous and nearly tasteless, fuses at $162^{\circ} C.$ ($323.6^{\circ} F.$), and sublimes on carefully regulating the heat. It is almost insoluble in cold water, but imparts a bright-yellow color to boiling water, and requires 224 parts of boiling 86 per cent. alcohol for solution. It crystallizes from its concentrated solutions in hot alcohol, amylie alcohol, glacial acetic acid, and ether, and is freely soluble in benzol, chloroform, fixed and volatile oils, and the hydrocarbons of coal-tar. Strong sulphuric acid dissolves it with a bright-red color, and separates it again in yellow floccules on adding the solution to water. Alkalies dissolve it with a deep-red color; the solutions produce with alum a rose-colored lake, and with lead salts precipitates which may vary in color from yellowish to pinkish or bright-red. (See also *CHRYSAROBINUM*, p. 449.)

After washing the alcoholic extract of rhubarb with water, dissolving the residue in a small quantity of alcohol, and mixing the solution with ether, a precipitate is obtained consisting of *phaeoretin*, *aporetin*, and resinous matter. The liquid yields chrysophanic acid on concentration, while the mother-liquor contains *erythroretin*, $C_{38}H_{30}O_{14}$, which is a yellow tasteless powder readily soluble in alcohol, less freely soluble in ether and glacial acetic acid, and dissolves in alkalies with a purple color. By treating crude chrysophanic acid with cold benzol, *emodin*, $C_{15}H_{10}O_3$, is left behind; this crystallizes from hot benzol in orange-colored prisms which dissolve in alkalies with a deep-red color; it was discovered by Warren de la Rue and Müller (1857). The precipitate by ether obtained as above contains *aporetin*, and yields to cold alcohol *phaeoretin*, $C_{32}H_{32}O_{14}$, which is yellowish-brown and soluble in alkalies with a dark red-brown color. *Aporetin* is a blackish resinous mass, sparingly soluble in alcohol, ether, benzol, and chloroform, and yields with alkalies a brown solution.

Kubly (1867) isolated from rhubarb, besides *phaeoretin*, *chrysophan*, $C_{27}H_{30}O_{14}$ (Liebermann), which is orange-colored, bitter, insoluble in ether, soluble in alcohol, and more freely so in water, and by acids is split into sugar and chrysophanic acid; a colorless, crystallizable, neutral and tasteless body, having the composition $C_{10}H_{12}O_4$; and *rheotannic acid*, $C_{52}H_{32}O_{28}$, which is insoluble in ether, soluble in water and alcohol, precipitates gelatin and albumen, yields with ferric salts a black-green precipitate, and when boiled with dilute acids is resolved into sugar and *rheumic acid*, $C_{40}H_{32}O_{18}$. This acid closely resembles rheotannic acid, but is sparingly soluble in cold water and yields dark-blue precipitates with ferric salts. Rhubarb contains also sugar, fat, pectinaceous matter, and starch. The ash left on incineration varies in amount; good rhubarb yields about 12 or 14 per cent., but sometimes as high as 43 per cent. has been obtained (*Pharmacographia*).

Other Rhubarbs.—*Rheum raphaniticum*, *Linné*, is indigenous to Asia Minor, Southern Siberia, and South-eastern Russia. It has a large conical fleshy root and cordate-ovate rather obtuse leaves on long fleshy, pleasantly acidulous petioles, the upper part of which has a shallow channel. This species is extensively cultivated as *pie-plant* for the sake of the leaf-stalks, and the root is occasionally employed in domestic practice. The same species is also cultivated in Moravia, Hungary, and near Banbury, England, and yields the Austrian or Moravian and the English rhubarb. In some parts of Russia, Germany, and France, *Rheum palmatum*, *Linné*, is likewise cultivated; and experiments have also been made with *Rh. undulatum*, *Linné*, *Rh. compactum*, *Linné*, and *Rh. Emodi*, *Wallich*, s. *Rh. australe*, *Don*. The various kinds of rhubarb grown in Europe are often very handsome in appearance, though usually of a lighter color than good Chinese rhubarb, and generally of smaller dimensions. The medullary rays usually radiate pretty regularly from the centre, but in interrupted lines; the cambium-zone is more distinct, the stellate spots are entirely wanting or present only in small numbers, and the outer surface shows, after trimming, the short striae of the brownish-red medullary rays, but white meshes are rarely seen.

FIG. 239.

European Rhubarb: transverse section.

Tests.—It has been stated above that unsightly pieces of rhubarb are occasionally rendered more attractive in appearance by turmeric: the same is the case with powdered rhubarb. For the detection of this sophistication W. L. Howie (1873) recommended the following test: About 5 grains of rhubarb are placed upon white blotting-paper; a few drops of chloroform are percolated through the powder, when the paper surrounding the powder will become very slightly stained from good Chinese rhubarb, while European or dark-colored Chinese rhubarb will produce a deep-yellow stain similar to turmeric. A pinch of powdered borax is now placed on the stain, and a single drop of hydrochloric acid placed upon it; if the stain was produced by rhubarb its color will not be affected, but if the rhubarb contained turmeric the color will change to a distinct red in a few seconds.

Allied Drugs.—*PEREZIA ADNATA*, *Gray* (*Trixis Pipitzahoe*, *Schaffner*, *Dumerilia Alami*, *De Candolle*), nat. ord. Composite, Labiati floræ. This is a plant of Central Mexico, the root of which is used as a laxative. It is described by Th. Greenish (1884) as 3 to 4 inches (8–10 Cm.) long, $\frac{1}{2}$ inch (2 Mm.) thick, longitudinally wrinkled, brown, bitter, and rather persistently pungent; it has a thick central pith surrounded by about eight short fibre-vascular bundles, on the outside of which, in the thickish bark, are contained a number of cells forming a circle and containing a yellow crystalline substance; stone-cells of a somewhat stellate appearance are scattered in the parenchyma. The yellow principle, *pipitzahoe acid*, $C_{15}H_{10}O_8$, was examined by C. M. Weld (1855): it crystallizes in golden-colored glossy scales or plates; hence it has been called *vegetable gold*: it is nearly insoluble in cold water, dissolves readily in alcohol and ether, melts near 100° C., sublimes when heated with care, and acquires an intense purple color with alkalis and alkaline earths. The same compound was obtained by Charles Mohr (1884) from the root of *Perezia Wrightii* and *P. nana*, *Gray*, of South-western Texas—from the latter in smaller quantity: it separates from the decoction in needles. The acid acts as a drastic purgative in doses of 4 to 8 grains (0.25–0.50 Gm.).

RHINACANTHUS COMMUNIS, *Nees* (nat. ord. Acanthaceæ). This shrub is indigenous to India and China. The woody root and leaves have been used in ringworm and other cutaneous diseases. The leaves are 2 to 4 inches (5–10 Cm.) long, ovate-oblong, entire, obtuse, and finely pubescent. The root contains in intercellular spaces of the bark a quinone-like body, which Liborius (1881) called *rhinacanthin*, $C_{11}H_{18}O_4$, which forms with alkalis intensely red compounds, and these are decomposed by benzin, dissolving the rhinacanthin with a yellow color.

Medical History.—The terms *rhabarbarum* and *rheum* are derived from the name of the river Rhâ (Volga) which empties into the Caspian Sea, because from that direction rhubarb was anciently, as at present, brought to the countries bordering on the Levant. Two names were used to designate it, *Rha-ponticum*, and *Rha-barbarum*, of which the former revealed its source near the Pontic or Euxine Sea, and the other that it was brought from the barbarous regions of the North. *Rhapontic* rhubarb is said, however, to have been astringent and not purgative. Certain it is that the earliest account of the cathartic rhubarb comes to us through the Arabian writers, who insist upon its combined

tonic and purgative qualities, and its astringency when roasted. Rhubarb was, however, well known in China from time immemorial as a purgative.

Physiological Action.—Rhubarb acts a purgative on horses and dogs as well as on man, and in all cases its coloring and purgative principles are absorbed into the blood, since it tinges the urine and milk, and renders the latter purgative. It also sometimes stains the perspiration yellow. The color which it gives the feces probably led to its being regarded as a cholagogue, but the experiments of Rutherford led him to conclude that it is really so independently of its purgative action. Its purgative and astringent properties have been ascribed to cathartine (?) and rheo-tannic (?) acids respectively. After large doses a moderate purgative action is followed by quiescence of the bowels; but a very small quantity taken daily in mass and allowed to dissolve in the mouth will maintain them in a free condition for some time, and that without at all impairing the digestion. The purgative action of rhubarb has been manifested when it was applied to ulcers or moistened and rubbed upon the skin.

Medical Uses.—The gentle action of rhubarb renders it one of the best remedies for *hemorrhoids* connected with constipation. Its tonic or astringent influence superadded to its laxative operation constitutes it one of the best remedies for *diarrhœa* due to cold or to the presence of irritating ingesta in the bowels; and for this purpose roasted rhubarb is thought to be peculiarly efficient. It is prepared by roasting fragments of rhubarb like coffee. The diarrhœa to which children are liable in summer is often cured by this medicine, especially when associated with magnesia. At one time rhubarb was believed to be a valuable remedy for *dysentery*, but in this disease, which presents so many types and varieties, it is difficult to determine in what particular form of it the medicine is most efficient. We believe that it is so in the first stages of simple dysentery when associated with mild salines, in the decline of the bilious form with a tendency to protracted diarrhœa, and as an occasional purgative in chronic dysentery prolonged by scybala in the bowels.

Externally, powdered rhubarb has been recommended as a stimulant and astringent application to old, indolent, and irritable *ulcers*. Opium, calomel, and other substances may be mixed with it.

The *dose* of rhubarb as a purgative is about 20 grains (Gm. 1.30); as a gentle aperient and tonic, 5 grains (Gm. 0.30). Associated with calomel, its action is prompt and efficient. With magnesia it is very appropriate when the secretions of the stomach and bowels are unduly acid. The simple rhubarb pill, which contains soap, is very eligible as a mild laxative for habitual or occasional use. The numerous official preparations of this drug are commented upon in their proper places.

RHODODENDRON.—ROSEBAY.

Snow rose, E.; *Rosage*, Fr.; *Alpenrose*, *Schneerose*, *Gichtrose*, G.

Nat. Ord.—Ericaceæ, Ericineæ.

Description.—This genus is composed of evergreen shrubs and low trees inhabiting mountainous localities of the northern hemisphere. They have leathery, entire, somewhat revolute and petiolate leaves, often crowded near the end of the branches, and showy flowers in compact terminal clusters or corymbs, with the corolla five-lobed, funnel-form, and somewhat campanulate or with a wheel-shaped border. The leaves of the following species have been used:

RHOD. CHRYSANTHUM, *Linné*. It is indigenous to Siberia, and has yellow flowers. The leaves are about 2 inches (5 Cm.) long, oblong or obovate-oblong, rather obtuse, reticulate, smooth, pale rust-colored beneath. When fresh they have a slight rhubarb-like odor, which is nearly lost in drying; their taste is astringent, unpleasantly bitter, and somewhat pungent.

RHOD. MAXIMUM, *Linné*. It grows in North America, and has rose-colored or whitish flowers. Its leaves are about 7 inches (18 Cm.) long, elliptic-oblong, or obovate-oblong, acute, smooth, dark-green, shining, paler beneath. Their taste is astringent and somewhat pungent.

RHOD. FERRUGINEUM, *Linné*. It is found in Europe and Asia and has purple glandular-dotted flowers. The leaves are about 1½ inches (4 Cm.) long, lanceolate or lance-oblong, rust-colored and scaly beneath, and have an astringent and bitter taste.

Constituents.—These leaves contain tannin, a little volatile oil, resin, etc. The bitter principle of the last-named species was found by R. Schwarz to be *ericolin* (see page 879).

Medical Action and Uses.—The Siberian or snow rose is said to be a very active medicine. It is related that a goat after eating its leaves became excited, then tottered and fell upon its knees, and did not recover for 2 hours. In man small doses appear to increase the secretions, and especially to act as a diaphoretic. Larger doses render the mouth and throat dry and constrict them, promote the alvine and cutaneous secretions, and excite a sense of formication and prickling in the skin, which also exhales an aromatic smell. In still larger doses it causes giddiness, confusion of the senses and ideas, dimness of vision, constriction of the throat, dyspnoea, hebetude, paralysis of sensibility and motility, and even convulsions. Sometimes it acts principally as an evacuant upon the stomach and bowels, and in other cases excites profuse diuresis or sweating, itching or eruptions of the skin, pain and twitching of the limbs, etc. It is said to reduce the pulse and render it intermittent.

Rosebay has been almost exclusively employed in the treatment of *rheumatism* and *gout*, a hot infusion being used at the commencement of the attack when acute; but in the chronic forms of these diseases a moderate but steady action of medicine is maintained for weeks, and even months, the evidence of its utility being furnished by painful sensations in the affected parts. It has also been used in *sciatica*, in chronic *diseases of the skin*, and chronic *diarrhoea* and *dysentery*. It is given in powder in doses of 10 grains (Gm. 0.60) several times a day, or in a decoction made with from 2 to 4 drachms of the leaves in 10 fluidounces (Gm. 8–16 in Gm. 320) of water.

RHEADOS PETALA, Br.—RED-POPPY PETALS.

Flores rhæados.—*Corn poppy*, *Corn rose*, E.; *Coquelicot*, *Pavot rouge*, Fr.; *Klatschrose*, *Klapperrose*, G.

The fresh petals of *Papaver Rhæas*, *Linné*. Bentley and Trimen, *Med. Plants*, 19.

Nat. Ord.—*Papaveraceæ*.

Origin.—The red poppy is an herbaceous annual growing in fields among cereals throughout the greater part of Europe, in Northern Africa, and in Asia eastward to India. It is about 2 feet (60 Cm.) high, is covered with spreading hairs, has deeply pinnatifid leaves with the segments lanceolate and cut-toothed; it has showy red flowers, and produces short, smooth, obovate capsules, which are truncate above and contain numerous minute blackish seeds.

Description.—The petals are roundish in outline, 2 inches (5 Cm.) and more in width, one pair always broader than the other pair, deep scarlet-red, after drying of a dull purple, very thin, with a short claw and a black spot near the base. Their odor in the fresh state is heavy and somewhat narcotic, and is dissipated in drying; their taste is mucilaginous and slightly bitter.

PAPAVER DUBIUM, *Linné*, which is sometimes met with spontaneously in the United States, is appressed-hairy and has a club-shaped capsule and roundish-oblong, red petals, which agree in sensible properties with the preceding, but are generally smaller.

Constituents.—Red-poppy petals have been frequently examined, and it has been asserted by some that they contain small quantities of morphine, paramorphine, and narcotine, which alkaloids, however, could not be detected by other investigators. According to Hesse (1865), they contain *rhæadine* (see p. 1106). Leo Meier (1846) found in the petals gum, starch, albumen, fat, and wax, and two deliquescent coloring principles—*rhæadic acid*, which is dark-red, soluble in alcohol and water, but insoluble in ether, and yields brown compounds with alkalis; and *papaveric acid*, which is bright-red, soluble in dilute alcohol and water, and forms violet compounds with the alkalis. Hesse found the milk-juice of the plant to become deep-red with ferric chloride; it probably contains meconic acid.

Off. Prep.—*Syrupus rhæados*, Br.

Medical Action and Uses.—The dried petals of the red or corn poppy are used in the preparation of syrup of red poppy.

RHUS GLABRA, U. S.—SUMACH.

Smooth sumach, *Pennsylvania or upland sumach*, E.; *Sumac*, Fr.; *Sumach*, G.

The fruit of *Rhus glabra*, *Linné*.

Nat. Ord.—*Terebinthaceæ*, *Anacardiæ*.

Origin.—The smooth sumach is a shrub or suffrutescent plant growing in rocky and barren soil in North America. It attains a height of about 12 feet (3.6 M.). The stem

has a large pith and a thin circular layer of white wood, which is covered with a thin brown-gray bark having small scattered warts on the outer surface, the inner tangential layers of a green and the inner surface of a brown color. The leaves are imparipinnate, with from twenty-one to thirty-one lance-oblong, pointed, and serrate, on the under side whitish, leaflets. The small greenish flowers grow in dense ovoid terminal panicles, and appear in June; the fruit ripens in September.

Description.—The fruit is drupaceous, subglobular, less than $\frac{1}{4}$ inch (3 Mm.) in diameter; is densely covered with bright purplish-red hairs, and encloses a roundish oblong smooth putamen. It is inodorous and has a strong and pleasant acidulous taste. The leaves and bark, which have also been employed medicinally, have an astringent and bitter taste.

Constituents.—Trommsdorff (1834) found in the fruit of the European sumach tannin, coloring matter, malate of potassium, and much malate of calcium. Similar results were obtained by W. B. Rogers (1835) with the fruit of *Rhus glabra* and *copallina*. The seeds contain fixed oil. The astringent taste of European sumach-leaves was ascertained by Chevreul to be due to tannic and gallic acids, and Stenhouse (1862) corroborated this result by converting the tannin into gallic acid. He attributes the variation in the amount of tannin to the fact that the European sumach-leaves are collected also from *Rhus Cotinus*, *Liné.* Bowman (1869) estimated the tannin in *Rhus glabra* by means of gelatin, and found in the bark 8.75 and 14.55 per cent., and in the fruit 1.9 per cent.

Allied Species.—*RHUS COPALLINA*, *Liné.* Dwarf sumach. It is from 3 to 7 feet (.9–2.1 M.) high, and has downy branches and the petioles wing-margined between the lanceolate entire leaflets.

RHUS TYPHINA, *Liné.* Staghorn sumach. It is 20 to 30 feet (6–9 M.) high, velvety-hairy, and has leaves with from seventeen to thirty-one oblong-lanceolate, pointed, and sharply serrate or cut-toothed leaflets.

RHUS AROMATICA, *Aiton*, Sweet sumach. It is about 5 feet (1.5 M.) high, has petiolate aromatic leaves, with three sessile rhombic-ovate cut-toothed leaves, and produces yellowish flowers in ament-like spikes. The root-bark is about $\frac{1}{2}$ inch (2 Mm.) thick, covered with a fissured and warty brown cork (underneath which the bark is orange-red), and is whitish or pale-brownish in color. It is brittle, breaks with a short granular fracture, yields an ochre-colored powder, and has a slight pleasant odor and an astringent, aromatic, and bitterish taste. The bark contains scattered oil-cells, and has a somewhat checkered appearance from the tangential arrangement of the bast-layer and the radiating delicate medullary rays. H. W. Harper (1881) found it to contain volatile oil, several resins, fat, tannin, gum, etc., and to yield 13.8 per cent. of ash. A tincture has been used made with alcohol, and representing in the pint 4 troyounces of the bark. The fluid extract is prepared with alcohol in the same manner as fluid extract of ginger.

RHUS CORIARIA, *Liné.* European sumach. It is 8 to 12 feet (2.4–3.6 M.) high, and grows near the Mediterranean; the leaves have eleven to fifteen elliptic, coarsely serrate, woolly leaflets. From fifteen to twenty million pounds of this sumach are annually imported.

All the above species have red, hairy, acidulous fruits and astringent leaves, and, with the exception of the last, are indigenous to North America.

Medical Action and Uses.—Sumach-berries, containing both an acid and an astringent principle, may be used in infusion (5j to Oj = Gm. 32 to Gm. 250) as a gargle in catarrhal and other mild forms of pharyngitis, for which it forms a very agreeable and efficient remedy. Even in the decline of graver forms of this affection it is deserving of attention. The same is true of its use in aphthæ and other forms of sore mouth, including that produced by mercury. An infusion or decoction of the leaves or of the inner bark of the root is simply astringent, but may be applied to the same purposes, as well as for dressing wounds and ulcers. The glandular excrescences on the leaves are powerfully astringent.

Rhus aromatica, or sweet sumach, is reported to have such an action on the pelvic organs as to be useful in hæmaturia, enuresis, and leucorrhœa. In a case of so-called hysterical incontinence of urine it almost immediately caused a suspension of the infirmity when given as a fluid extract in doses of from 10 to 30 drops several times a day (*Centralbl. f. Therapie*, i. 207).

RHUS TOXICODENDRON, U. S.—RHUS TOXICODENDRON.

Toxicodendron, U. S. 1870; *Folia toxicodendri*.—Poison oak, E.; *Sumach vénéneux*, Fr.; *Giftsumach*, G.

The leaves of *Rhus Toxicodendron*, *Liné.*

Nat. Ord.—Terebinthaceæ.

Origin.—The poison oak is indigenous to Canada and the greater portion of the United States westward to the Rocky Mountains. It attains a height of about 40 inches (1 M.), and has an erect stem, or, if growing in close proximity to trees or walls, it becomes a climber, supporting itself by adventitious roots, and ascends to the height of 30 or 40 feet (9–12 M.). This climbing shrub, *Rhus radicans*, *Linné*, is now regarded merely as a variety of the erect form, but is popularly distinguished as *poison ivy*. Both forms, when wounded, emit a milky juice which turns black on exposure; they have the small pale greenish pentamerous flowers in axillary paniculate racemes, and produce small dry drupaceous fruits of a whitish color. The juice may be employed as an indelible ink, but is soluble in ether. The leaves are employed, and should be collected from May to July, while the shrub is in bloom. The plant has been introduced into Europe, and has become naturalized there.

Description.—The leaves are on petioles 4 or 5 inches (10–12 Cm.) long, and are trifoliate, with the terminal leaflet prominently stalked, ovate or oval, acuminate, and with a wedge-shaped base. The lateral leaflets are sessile, 4 or 5 inches (10–13 Cm.) long, pointed, rounded at the base, and obliquely ovate in shape, the lower half being broadest. The leaflets are either entire or variously notched, coarsely toothed or lobed, smooth above, somewhat downy beneath, and after drying thin and papery; they are inodorous, and have a somewhat astringent, saline, and acrid taste. The leaves are said to have been confounded with those of *Ptelea trifoliata*, *Linné* (see p. 1249), which are thicker, pale-green, and have three sessile leaflets.

Constituents.—Khittel (1858) found in the leaves of poison oak tannin, producing a green-black precipitate with ferrie salts, fixed oil, wax, mucilage, and other principles commonly found in plants. He believed the poisonous properties to be due to a volatile alkaloid. But we found (1865) the exhalations of this plant to have an acid reaction, and the leaves to contain notable quantities of ammonia, but no other alkaloid, or only minute traces of such a compound. The poisonous *toxicodendric acid* is volatile, has a strongly acid reaction, neutralizes bases completely, and yields with an excess of oxide of lead a soluble salt having a strong alkaline reaction. The aqueous solution of the acid produces with lead acetates heavy white precipitates, yields with nitrate of silver, on boiling, a black precipitate of oxide of silver, and separates metallic gold from a warm solution of chloride of gold. Its neutral salts produce with mercurous salts a white precipitate, changing to black when heated. Potassium permanganate is readily reduced both by the acid and its salts. Toxicodendric acid resembles both formic and acetic acid in some of its reactions, and, according to the unpublished researches of H. P. Pettigrew (1883), who verified the above observations, the neutral solutions of its salts yield also a red color with ferrie salts. Applied to the skin either in solution or in the state of vapor, the acid produces vesicular eruption.

Pharmaceutical Preparations.—The expressed juice of the fresh leaves preserved by alcohol probably possesses all the virtues of the drug.

TINCTURA TOXICODENDRI. The bruised fresh leaves are macerated for 10 days with an equal weight of alcohol, and the liquid expressed and filtered.—*F. Cod.*

Allied Plants.—*Rhus diversiloba*, *Torrey et Gray* (*Rh. lobata*, *Hooker*), is a straggling or climbing shrub of the Pacific coast of North America, and has the leaves with three or five more or less deeply lobed or pinnatifid leaflets.

Rhus venenata, *De Candolle* (*Rh. Vernix*, *Linné*). This species grows in swampy localities in Canada and the United States, and is known as *poison sumach*, *poison dogwood*, and *poison elder*. It is a shrub 12 to 18 feet (3.6 to 5.4 M.) high, and has very glabrous leaves, with about eleven oval or obovate-oblong, abruptly pointed, and entire leaflets. The fruit is yellowish.

Rhus pumila, *Michaux*, is a procumbent shrub of Western South Carolina, and has pubescent pinnate leaves, with about eleven oval or oblong, coarsely-toothed, and somewhat acuminate leaflets. The fruit is red and softly hairy.

Rhus metopium, *Linné*. The *coral sumach*, *bum-wood*, or *mountain-machineel*, grows in Southern Florida and the West Indian islands. It is about 30 feet (9 M.) high, and has leaves with five long-stalked ovate entire and smooth leaflets. The wood contains much tannin: the fruit is about $\frac{2}{3}$ inch (1 Cm.) long, red and acrid.

All the species named are poisonous, and their properties are probably due to the same principle.

Physiological Action.—Poison oak was well known to the aborigines, and early described by travellers in North America, both as a poison and as a medicine. The volatile acid emanations of the living plant produce an eczematous eruption upon the skin, and it is alleged that a dog exposed to them died with a general swelling of the body. Herbivorous animals devour its leaves with impunity, but dogs are poisoned by its juice.

losing their power of muscular co-ordination and strength, and dying with dilated pupils, without coma or convulsions. On man it acts externally as an irritant, some persons being much more susceptible than others to its influence. Even air impregnated with the exhalations of the leaves is sufficient to produce an eczematous inflammation of the skin. This is characterized by violent itching, redness, and swelling, followed by heat, pain, fever, and vesication, which, upon the face and genitals particularly, may be attended with extreme tumefaction. These symptoms begin between a few hours and several days after the application of the poison, and are usually at their height on the fourth or fifth day, after which desquamation commences. But sometimes they continue active for a longer time. The juice of the plant applied to the skin will, in the course of 48 hours, produce a blister which is soon surrounded with vesicles, and later a similar eruption may take place upon distant parts of the body without the primary blisters having been ruptured. The eruption is attended with severe burning and itching. Usually, however, the more distant irritation is due to the discharge from the primary one being conveyed elsewhere by the hands. But there are some cases of poisoning by this plant, taken internally, which were attended with a vesicular eruption of the skin. A case is reported of a woman who used the leaves of the plant instead of paper after defecation, and who suffered, besides the general affection of the skin, from symptoms of inflammation of the rectum (*Phil. Med. Times*, xii. 636). Internally, it gives rise to a species of intoxication, with vertigo, confusion of the senses, dilatation of the pupils, a sense of constriction of the temples, chilliness, nausea, thirst, a slow, small, and irregular pulse, diaphoresis and diuresis, debility, faintness, trembling, and convulsions. Two children who between them had eaten a pint of the berries became drowsy and stupid, and then delirious and convulsed.

Various remedies have been employed to palliate the inflammation caused by poison oak. One of the best is alum-curd, which is appropriate at all stages of the process. Before the blisters have fully formed or have discharged their contents lead-water is useful, but a weak solution of ammonia or a strong one of carbonate or the sulphite of sodium, or the solution of chlorinated soda, is perhaps still more so. Cosmoline allays the itching and burning. When the blisters are mature or have been ruptured, a solution of perchloride or of persulphate of iron or of sulphate of zinc, or simply lime-water, carefully applied to the vesicated skin, will arrest the progress of the inflammation. *Grindelia squarrosa* has also been used for this purpose (see p. 749).

Medical Uses.—The inflammation of the skin which poison oak excites led to its being employed substitutively in chronic *cutaneous affections*, but ineffectually. It has been alleged (Trousseau) to be efficacious in the treatment of *paraplegia* from concussion of the spinal marrow, and other affections of this organ without lesion of tissue; it is said to occasion no inconvenience, and to strengthen rather than enfeeble digestion. Sometimes a slight degree of stranguary is observed. It has also been used to cure *incontinence of urine* depending upon atony of the bladder. One physician has found it useful in spinal anæmia if associated with *nux vomica*, and that it reduces the temperature if administered with gelsemium; which may very readily be credited.—much more readily than that it is “a laxative, diaphoretic, diuretic, and particularly a stimulant of the nervous system,” which is asserted by the same authority (*Detroit Lancet*, Jan. 1880). The *dose* of the powdered leaves is stated to be 5 grains, which should be gradually increased to 60 grains (Gr. 0.30–4). On the whole, the medicinal virtues of this plant are too uncertain to inspire any confidence.

ROBINIA.—LOCUST TREE.

False acacia, E.; *Robinier*, Fr.; *Falsche Akazie*, G.

Robinia Pseudacacia, Linné.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Description.—The common locust tree is indigenous to the southern part of the United States, but is commonly cultivated and naturalized farther north and in Europe. It is thorny when young, attains a height of 60 or 80 feet (18 to 24 M.), but is smaller in northern localities, and has a durable white or reddish wood and a brownish or gray, smooth, and internally yellowish bark. Its leaves are imparipinnate, the leaflets in from eight to twelve pairs, oval, obtuse, and smooth, and the fragrant whitish flowers in long slender racemes. The legume is about 3 inches (8 Cm.) long, linear, flat, margined on the inner side, and contains about six blackish-brown small seeds. The root and inner bark have a sweetish taste.

Constituents.—The root was examined by H. Reinsch (1845), who found it to contain much albumen, tannin, sugar, starch, and other common vegetable principles. His *robinic acid* is believed by Illasiwetz (1852) to be *asparagin*, of which he obtained 2½ ounces from 30 pounds of the root. According to Zwenger and Dronke (1861), the flowers contain a yellow glucoside, *robinin*, which, on being boiled with acids, is resolved into sugar and *quercetin*, and which is also contained in the bark and wood.

Medical Action and Uses.—The bark of the root is said to be tonic, and in large doses purgative and emetic, and a syrup prepared from the flowers is related to have produced acro-narcotic effects in children. Gendron mentions that certain boys who had chewed some of the bark and swallowed the juice were affected not only with vomiting, but with coma and slight convulsions (Griffith, *Med. Botany*). No definite information concerning its medicinal virtues is accessible.

ROSÆ CANINÆ FRUCTUS, *Br.*—HIPS.

Cynosbata, *Fructus cynosbati*.—Fruit of the dog rose, E.; *Gratte-cul*, *Cynorrhodon*, Fr.; *Hagebutten*, *Hainbutten*, G.

The ripe fruit of the dog rose, *Rosa canina*, *Linne*, and other indigenous allied species. Bentley and Trimen, *Med. Plants*, 103.

Nat. Ord.—Rosaceæ, Roseæ.

Origin.—The *dog rose* is a spiny European shrub, from 4 to 8 feet (1.2–2.4 M.) high, and resembles the roses indigenous to this country, but differs from them in the shape of the calyx and in the absence of glandular hairs on the peduncle and calyx.

Description.—Hips are not the fruit, but the enlarged calyx-tubes, of the rose. They are about an inch (25 Mm.) in length, ovate, contracted above, of a bright-red color, shining, internally stiff-haired, and enclose a number of ovate, hairy, brownish, bony akenes. Hips are at first tough and crowned with the five-cleft deciduous calyx-lobes: later in autumn they are naked above, softer, and more fleshy. They are inodorous and have a sweet acidulous and somewhat astringent taste. For medicinal use the hard akenes are removed and the fleshy calyx-tube alone is employed. The corresponding part of *Rosa carolina*, *Linne*, and *R. lucida*, *Ehrhart* (Meehan, *Native Flowers*, i. 169; ii. 133), is depressed globular, the former somewhat hairy, and has properties similar to those of the first.

Constituents.—Scheele already noticed malic and citric acid in the pulp. Biltz (1824) obtained 7.78 per cent. of malic and 2.95 per cent. of citric acid; also 30.6 per cent. of sugar, 25 per cent. of gum, and small quantities of tannin, resin, wax, malates, citrates, and other salts.

Off. Prep.—Confectio rosæ caninæ, *Br.*

Medical Action and Uses.—Hips are described as slightly refrigerant and astringent, but they are used in medicine only to prepare the confection of hips.

ROSA CENTIFOLIA, *U. S.*—PALE ROSE.

Rosæ centifoliæ petala, *Br.*; *Flores rosæ*, *P. G.*; *Flores rosarum incarnatarum*.—Cabbage-rose petals, Hundred-leaved rose, E.; *Rose à cent feuilles*, *Rose pâle*, Fr.; *Centifolienrose*, *Rosenblätter*, G.

The petals of *Rosa centifolia*, *Linne*. Bentley and Trimen, *Med. Plants*, 105.

Nat. Ord.—Rosaceæ, Roseæ.

Origin.—This well-known shrub, which is by some botanists regarded as a cultivated variety of the red rose, is probably indigenous to Western Asia, and is cultivated in innumerable varieties in all countries. Its branches are covered with numerous nearly straight spines; the petioles and peduncles are nearly unarmed, but more or less clothed with glandular bristles, and the leaves have five, or sometimes seven, ovate or elliptic-oval serrate glandular and beneath soft-hairy leaflets. The flowers are collected and deprived of the calyx and ovaries, the petals alone being employed.

Description.—The petals are roundish-obovate, retuse at the apex or almost obovate, of a pink color, a delicious rose odor, and of a sweetish, somewhat bitter, and slightly astringent taste. In drying they become brownish and less fragrant.

Constituents.—The odor of rose-petals is due to a minute quantity of volatile oil (see page 1081). Enz (1867) determined the other constituents to be tannin, giving a green reaction with ferrie salts, fat, resin, sugar, mucilage, a bitter principle, malates, tannates, and phosphates, and a coloring matter which is easily altered, and, from the

investigations of Fremy, Cloëz, Filhol, and others, seems to be identical with that of the red rose and of many other red-colored flowers.

Pharmaceutical Uses.—Rose-petals are employed chiefly in the distillation of rose-water, and are for this purpose often preserved by being packed into suitable vessels with one-half or their own weight of common salt. It is stated that in some laboratories the entire rose-flowers are used in the distillation of rose-water, and furnish a good product. The dried petals are used in preparing *Syrupus sarsaparillæ comp.*, *U. S.*

Medical Action and Uses.—Pale rose-leaves are seldom used medicinally except in the form of the official rose-water. The nervous symptoms and occasionally the coryza ascribed to fresh roses are apt to be produced by other odorous flowers.

ROSA GALLICA, *U. S.*—RED ROSE.

Rosæ gallicæ petala, Br.; *Flores rosarum rubrarum*.—*Red-rose petals*, E.; *Rose rouge*, *Rose de Provins*, Fr.; *Essigrose*, *Sammtrose*, *Zuckerrose*, G.

The petals of *Rosa gallica*, *Linné*. Bentley and Trimen, *Med. Plants*, 104.

Nat. Ord.—Rosaceæ, Roseæ.

Origin.—The red rose is a bushy shrub 2 or 3 feet (60–90 Cm.) high, which grows wild in Southern Europe and the Levant and is cultivated in gardens in numerous varieties. It is armed with bristly prickles and with a few curved spines, and has slightly heart-shaped and thicker leaflets than the preceding species. The flowers are collected while still in bud, and the petals cut off near the base and rapidly dried.

Description.—As seen in commerce, red rose is in small cones consisting of the numerous densely-imbriated petals, which, when unfolded, are roundish, retuse at the apex, and at the base narrowed into a short yellow claw, the greater portion of which has been trimmed off; the centre of the cone is hollow or it contains some of the stamens. The color is deep purplish-red, velvety in aspect; the odor is roseate and the taste bitterish, slightly acid, and astringent. Red rose should be preserved in a dry place and excluded from the light.

Constituents.—The chemical constituents of red rose are very similar to, if not identical with, those of pale rose, but the astringent principle is more predominating. Filhol (1863) denied the existence of tannin in red-rose petals; by extracting them with ether two fats and *quercitrin* were obtained, to which the dark-green reaction with ferric salts is due; alcohol afterward took up a little gallic acid, and nearly 20 per cent. (?) of invert-sugar. Rochleder (1867), however, ascribed the reaction with iron to *quercetic* and a little gallic acid. The coloring principle of red rose was isolated by H. Lenier (1877) by exhausting the petals with ether, and afterward with alcohol; the tincture was precipitated by lead acetate, and this precipitate decomposed by an insufficient quantity of sulphuric acid in the presence of alcohol. The coloring matter becomes deep-red, with a bright-green fluorescence, by alkalis; it decomposes carbonates, yields with alkalis crystallizable compounds, and is precipitated by salts of alkaline earths and metals, the lead salt having the composition $Pb_2C_{21}H_{25}O_{30}$.

Off. Prep.—*Confectio rosæ* (rosæ gall.), *U. S.*, Br.; *Infus. rosæ acidum*, Br.; *Extr. rosæ fluid.*, *Mel rosæ*, *Pil. aloes et mastiches*, *U. S.*; *Syr. rosæ* (gallicæ), *U. S.*, Br.

Medical Action and Uses.—Red-rose leaves were anciently used in infusion as cooling and astringent for the relief of uterine and other hæmorrhages, and as an application to *aphthæ* and other *ulcers* affecting the mouth, ears, anus, etc., and the fresh bruised leaves were applied to inflammation of the *eyes*, etc.

A compound infusion of rose, containing sugar and diluted sulphuric acid (*U. S. P.* 1870), is employed as a coloring and flavoring ingredient of mixtures, and as an excipient and solvent for sulphate of magnesia and for sulphate of quinine, whose taste it partially covers. It forms an agreeable gargle for inflamed and ulcerated states of the *mouth* and *fauces*, and may be used to moderate profuse *sweats*. Its virtues are largely due to the sulphuric acid it contains. *Dose*, from 2 to 4 fluidounces (Gm. 64–128).

ROSMARINUS, *U. S.*—ROSEMARY.

Folia rosmarini, s. *oris marini*, *Folia anthos*.—*Feuilles de romarin*, Fr.; *Rosmarinblät-ter*, G.

The leaves of *Rosmarinus officinalis*, *Linné*. Bentley and Trimen, *Med. Plants*, 207.

Nat. Ord.—Labiata, Monardææ.

Origin.—Rosemary is a native of the basin of the Mediterranean, and is often cultivated in gardens. It is shrubby, 3 or 4 feet (.9–1.2 M.) high, much branched, evergreen, and has few-flowered axillary clusters of rather large pale-blue flowers.

FIG. 240.

Rosmarinus officinalis,
Linné.
branch and flower.

Description.—Rosemary-leaves are about 1 inch (25 Mm.) long, leathery, linear, entire, sessile, obtuse at both ends, dark-green above, densely woolly and dotted with oil-glands beneath, and revolute on the margin. In drying the margin becomes more strongly revolute, the leaf narrower and rigid, and the midrib prominent on the lower side. Rosemary has a peculiar aromatic somewhat camphoraceous odor and a pungently aromatic taste.

Constituents.—The principal constituent is the volatile oil (see page 1083). A little tannin, resin, and bitter principle are likewise present.

Pharmaceutical Uses.—The leaves are employed in the preparation of fumigating powders and the distillation of the volatile oil.

Medical Action and Uses.—By the ancients rosemary was esteemed for its emmenagogue, galactagogue, and diuretic virtues, and more recently it was regarded as diaphoretic and carminative, and as useful in various functional *nervous disorders*. In Europe it is sometimes still employed for similar purposes. The volatile oil is a powerful stimulant. According to Köhler and Schreiber, its chief action is upon the cerebro-spinal centres. Small doses increase and large doses diminish reflex excitability. When inhaled it greatly reduces the animal temperature, and it gives the urine a violaceous odor (*Edin. Med. Jour.*, xxiv. 1042). An infusion prepared with from 60 to 120 grains of the leaves in a pint of water (Gm. 4–8 in Gm. 500) may be prescribed in tablespoonful doses. Fomentations made with the plant steeped in hot water or alcohol are used for the relief of local pains. The oil may be

used for the same purpose, and is a valuable addition to various stimulant and anodyne liniments.

RUBIA.—MADDER.

Dyer's madder, E.; *Garance*, Fr.; *Krapp, Färberröthe*, G.

The root of *Rubia tinctorum*, Linné.

Nat. Ord.—Rubiaceæ.

Origin.—This plant is an herbaceous perennial indigenous to the Levant and Southern Europe, and is cultivated in several European countries. It is about 3 feet (90 Cm.) or more high, has elliptic-lanceolate, rough, prickly leaves in whorls of four or six, greenish-yellow flowers, and smooth, black, baccate fruits. 3,138,558 pounds of ground madder were imported into the United States in 1876–77, and 1,145,501 pounds in 1883; the importation of the whole root in the same periods was 43,100 and 398,726 pounds.

Description.—The rhizome is creeping, and has numerous long, light blood-red, cylindrical roots of the thickness of a quill. These are, after drying, deeply wrinkled, have an easily separable gray-red corky layer, a thin dark brown-red inner bark, and a spongy red wood, which in the fresh state is yellowish and contains irregular medullary rays. The rhizome is sometimes present; it resembles the root, and is chiefly distinguished by a central pith. The root breaks with a short and smooth fracture, has a feeble color, and a sweetish, bitterish, somewhat acrid and astringent taste. Madder is usually found in the shops in the form of a coarse powder.

Constituents.—Madder has been very frequently subjected to chemical investigation, and a large number of principles have been isolated, which are most likely oxidation- and decomposition-products of a yellow coloring matter found by Decaisne in the fresh root. Many of these are glucosides, and yield *alizarin*, besides other principles, under the influence of dilute acids. *Rubian* is an amorphous, dark-yellow, bitter mass. *Rubihydran* and *rubidihydran* are gum-like masses. These principles were isolated by Schunck (1847–56). Rochleder's *ruberythrinic acid*, $C_{20}H_{22}O_{11}$ (1855, etc.), crystallizes in silky yellow prisms. The most important constituent is *alizarin*, $C_{14}H_8O_4$, which crystallizes in orange-red sublimable needles, is soluble in boiling water, alcohol, and ether, and yields purple or red-colored compounds with bases. Other compounds obtained from madder are *rubitanic acid*, *rubichloric acid* (blue and green by warm hydrochloric acid), *purpurin*, *rubiretin*, *verantin*, etc. It contains also pectin, sugar, citric acid, etc. The

artificial production of alizarin was discovered by Graebe and Liebermann, and it is now manufactured from *anthracene*, $C_{14}H_{10}$, a crystalline constituent of coal-tar, which is oxidized to *anthraquinone*, $C_{14}H_8O_2$; this is then converted into a sulphonic acid or a bromo-compound, which by the action of alkalis yields alizarin.

Medical Action and Uses.—Madder is an obsolete medicine, but was formerly in high repute as an *emmenagogue*. It was administered in doses of $\frac{1}{2}$ drachm, gradually increased to a drachm (Gm. 2–4), four times a day.

RUBUS, U. S.—BLACKBERRY.

Écorce de ronce noir, Fr.; *Brombeerrinde*, G.

The bark of the root of *Rubus villosus*, *Aiton*, *Rubus canadensis*, *Linné*, and of *Rubus* *trivialis*, *Michaux*. Bentley and Trimen, *Med. Plants*, 100.

Nat. Ord.—Rosaceæ, Dryadeæ.

Origin.—These species are common shrubby North American plants with trifoliate or quinate leaves. *R. canadensis* is the *dewberry*, and has a trailing slightly prickly stem and nearly smooth ovate-lanceolate, sharply serrate leaflets. *R. villosus* is the common *American blackberry*, has an upright or reclining stem armed with stout recurved prickles, and is glandular and hairy on the branchlets and the lower surface of the leaflets, and ripens its fruit later than the first species. *R. trivialis* is the dewberry or bush-blackberry of the Southern United States, growing as far north as Maryland; it is armed with bristles and recurved prickles, and has coriaceous, evergreen, nearly smooth leaflets.

Description.—The roots of these species are considerably branched, vary in size from the thickness of a goosequill or less to the diameter of an inch (25 Mm.) or more, and contain a large whitish, tough, ligneous medullium. The bark is quite thin, blackish or in the dewberry blackish-gray externally, internally dark-brown, and the inner surface pale-brownish and smooth, tough, breaks with some difficulty, shows in the bast-wedges a tangential arrangement of the tissue, is nearly inodorous, and has a strongly astringent and somewhat bitter taste. The thinnest roots are frequently not deprived of the white, tasteless, and inert wood. The bark and leaves of most species of this genus have an astringent and somewhat bitter taste and the fruits are acidulous.

FIG. 241.

Rubus villosus: transverse section through bark, magnified 15 diameters.

Constituents.—Blackberry-bark contains tannin, of which C. F. Kramer (1882) obtained 10.2 per cent; its other constituents have not been investigated.

Off. Prep.—Extractum rubi fluid., Syrupus rubi, U. S.

Medical Action and Uses.—Blackberry-root and dewberry-root possess astringent and probably tonic virtues, and are much used in *summer complaint* and *infantile diarrhœa*. They are best administered in a decoction made with water or with milk, an ounce in $1\frac{1}{2}$ pints of liquid being boiled down to a pint (Gm. 32 in Gm. 750, reduced to Gm. 500).

RUBUS IDÆUS, U. S.—RASPBERRY.

Fructus rubi idæi.—*Framboises*, Fr.; *Himbeeren*, G.

The fresh root of *Rubus Idæus*, *Linné*.

Nat. Ord.—Rosaceæ, Dryadeæ.

Origin.—This shrub attains a height of about 6 feet (1.8 M.), is indigenous to the greater portion of Europe and to Northern Asia as far east as Japan, and is frequently cultivated. Areschong (1872) regards it as being derived from *Rubus strigosus*, *Michaux*, which is common in North America and Japan. The young shoots are glaucous, more or less bristly-spinous, and have imparipinnate leaves with one to three pairs of sessile, ovate, serrate, and whitish-downy leaflets. The flowers have five white petals, about as long as the calyx-lobes.

Description.—The fruit is hemispherical or subconical, and consists of about twenty or thirty small red velvety-hairy drupes, which are laterally coalesced and separate in a

collective mass from the dry conical receptacle. Raspberries, which are used in the fresh state only, contain a bright-red juice and have an agreeable fruity odor and a pleasant acidulous taste.

The fruit of the North American *Rubus occidentalis*, *Linne*, or *thimbleberry*, closely resembles the preceding, but is of a purplish-black color and has a dark-red juice.

Constituents.—Raspberries contain 4.5 to 8.7 per cent. of insoluble matter, .4 to .8 of ash, and 7 to 8.5 per cent. of organic constituents, about one-half of which is sugar, one-fourth is malic and citric acid, and the remainder consists of proteids, pectin, etc. The odor is due to a volatile oil consisting of compound ethers, and when distilled with water the distillate separates a white flocculent stearopten.

Off. Prep.—Syrupus rubi idæi, *U. S.*

Allied Fruits.—BLACK BERRIES.—Dewberries, *E.*; Mûres des haies, Baies de ronce, *Fr.*; Brombeeren, *G.*—The fruit of *Rubus villosus*, *Aiton*, of North America, *R. fruticosus*, *Linne*, of Europe, and allied species, has a fleshy receptacle, which remains united with the coalesced drupes, is of a black or blackish color, and contains a blackish-purple juice resembling in composition the juice of raspberries, but of a less delicate odor.

Medical Action and Uses.—The sole use of this fruit in medicine is to prepare an agreeable syrup.

RUMEX, *U. S.*—RUMEX.

Radix rumicis s. lapathi.—Yellow dock, *E.*; *Patience frisée*, *Fr.*; *Grindwurz*, *Mengelwurz*, *G.*

The root of *Rumex crispus*, *Linne*, and of other species of *Rumex*.

Nat. Ord.—Polygonaceæ.

Origin.—The *curled dock* is a European perennial, and has been extensively naturalized in North America and in other countries. It grows in waste places and in cultivated ground, and is distinguished from allied species by the wavy curled margins of its lanceolate leaves, and by the roundish-cordate, slightly denticulate, and grain-bearing valves of the fruit. The root is collected in autumn.

Description.—The root is 8 to 12 inches (20–30 Cm.) long, $\frac{1}{4}$ to $\frac{3}{4}$ inch (6–18 Mm.) or more thick, many-headed, fusiform, annulate above, somewhat branched and sparsely beset with fibres; after drying deeply wrinkled longitudinally, externally of a brown or reddish-brown color, inodorous, and of a bitter and astringent taste. The root breaks with a short irregular fracture, and upon transverse section shows a rather thick bark nearly one-sixth the diameter of the root, a dark-colored cambium-line, and a fleshy medullium, containing porous wood-wedges, separated by narrow medullary rays. The color of the inner tissue is white or whitish, after drying dingy brown-yellow, with yellowish or brownish-red striae. The roots of *Rumex obtusifolius*, *Linne*, and *R. sanguineus*, *Linne*, both indigenous to Europe and naturalized in North America, are indiscriminately collected with the preceding, and resemble it.

Constituents.—The chemical composition of yellow dock is nearly identical with that of rhubarb, except in the relative proportion of the constituents, the astringency predominating. The *rumicin* and *lapathin* of earlier investigators were proven by Tann (1858) to be identical with chrysophanic acid.

Off. Prep.—Extractum rumicis fluidum, *U. S.*

Medical Action and Uses.—Yellow dock is astringent, slightly tonic, and also laxative, and its operation has been compared to that of rhubarb, and also sarsaparilla. It has been chiefly used in chronic *cutaneous diseases*, particularly of a scrofulous nature. Some species of *Rumex* have been famous for the cure of *intermittent fevers*, for which purpose they were given in a hot decoction, to the production of sweating. Others have been regarded as eminently depurative, and used in chronic *hepatic congestion* and *dyspepsia* with lateritious urinary deposits and a tendency to *gout*. Externally, yellow dock has been applied to the treatment of various *skin diseases*, *glandular swellings*, and *scabies*. For the last an ointment is employed, made by boiling the root in vinegar until the fibre is softened; the latter is then reduced to a pulp and mixed with sulphur and lard. It is pretty certain that the sulphur is the efficient ingredient of this ointment. The root, softened by boiling, may be used as a stimulant and resolvent cataplasm. The decoction is made by boiling 2 ounces of the fresh root or 1 ounce of the dry root, bruised, in a pint of water (Gm. 64 or 32 in Gm. 500). Of this 2 fluidounces may be taken at a dose.

RUTA.—RUE.

Folia (Herba) rutæ.—*Rue, Rue des jardins, Fr.; Raute, Gartenraute, G.*

The leaves of *Ruta graveolens*, *Linne*. Bentley and Trimen, *Med. Plants*, 44.
Nat. Ord.—Rutaceæ.

Description.—Rue is an herbaceous or suffruticose perennial 2 or 3 feet (60–90 Cm.) high, which grows wild throughout Southern Europe and is frequently cultivated in gardens. The leaves are alternate, on long petioles, thrice or twice pinnate, or the upper ones pinnatifid, the lower ones 3 to 4 inches (7–10 Cm.) long, triangular-ovate in outline, subcoriaceous, grayish-green, finely pellucid-punctate and smooth; the final divisions obovate-oblong or spatulate, sparingly crenate, obtuse or rounded above, the terminal division larger and spatulate wedge-shaped. The plant has yellowish flowers in terminal corymbs and four- or five-lobed capsules containing numerous ovoid-angular blackish seeds. The leaves have a peculiar, strongly balsamic odor and possess an aromatic, bitter, and acrid taste.

Constituents.—The most important constituent of rue is its volatile oil (see page 1083). Machl found free malic acid. Weiss (1842) isolated the yellow coloring matter, *rutin*, $C_{25}H_{28}O_{15}$, and obtained it in needle-shaped crystals. Bornträger (1844) ascertained it to possess acid properties, and named it *rutinic acid*. Hlasiwetz (1855) observed that it splits into sugar and quercetin, and regarded it as identical with *quercitrin*; but Zwenger and Dronke found the unfermentable *rutin-sugar* to differ from isodulcitol and to have the composition $C_{12}H_{18}O_9$. P. Foerster (1882) obtained between 44.5 and 46.5 per cent. of quercetin. In preparing rutin it is with difficulty purified from resinous matter and a compound resembling coumarin.

Allied Drugs.—*EVODIA RUTECARPA*, *Bentham* (Rutaceæ), is a handsome Japanese shrub about 8 feet (2.4 M.) high. The thin, cylindrical, downy stalks and the unripe fruit are used; the latter are of the size of a small pea, five-grooved in the upper half, red-brown, glandular-pitted, and of a rutaceous odor and pungent taste. The drug is employed as a purgative and emmenagogue.

CAPPARIS SPINOSA, *Linne* (Capparidaceæ). The shrub is indigenous to the countries bordering the Mediterranean, and is sometimes cultivated. The flower-buds, preserved with vinegar and salt, constitute the commercial *capers* (Câpres, *Fr.*; Kapern, *G.*); they contain a volatile oil of an alliaceous odor, and a yellow coloring matter identical with *rutin*.

SOPHORA JAPONICA, *Linne* (Leguminosæ, Papilionaceæ). This tree, of Eastern Asia, is occasionally cultivated for ornament. It produces a large number of white or yellowish flowers, the buds of which are used as a substitute for hop and as a yellow dye under the name of *wajû* or *Chinese berries*. The coloring matter was regarded by Stein as being identical with *rutin*, but P. Foerster (1882) obtained from it—his *sophorin*—57.6 per cent. of isodulcitol and 46.8 of *sophoretin*, which resembles quercetin, but is not identical with it. The *sophorine* of Prof. H. C. Wood (1877–78) is a poisonous volatile alkaloid which gives a deep-red color with ferric chloride, and was obtained from the seeds of *Sophora speciosa*, *Bentham*, of Texas; and probably the same alkaloid has been found by Parsons (1879) in the seeds of *S. sericea*, *Pursh*, of Colorado and New Mexico.

Physiological Action.—Rue is an active irritant, as numerous cases of poisoning by it attest. In one example a man who had been gathering rue suffered from an inflammation of the skin of the forearms with abundant vesicles, which healed very slowly. Three cases are reported by one physician in which rue was used to produce abortion. In the first a decoction of the sliced root, in the second a decoction of the leaves, and in the third the expressed juice of the leaves, were taken. In one of the cases the effects were violent gastric pain, vomiting, or efforts to vomit, with the rejection of a little blood. In all there were great prostration, confusion of mind, cloudy vision, feebleness and slowness of pulse, coldness of the extremities, and twitching of the limbs. All of the patients, who were in the fourth or fifth month of pregnancy, aborted and recovered. In another case a woman had several times caused herself to abort by using an infusion of rue. The symptoms produced were pain in the back, bearing down, frequent micturition, continuing for several days and often attended with headache, when a “show” took place, followed by pains and abortion about 10 days from the beginning of the administration. Three doses of the oil of rue taken within an hour by a healthy adult produced uneasiness in the stomach, oppression and confusion of the brain, aching in the loins, an urgent desire to urinate, a strong smell of rue in the urine, flushes of heat, unsteadiness of gait, a tendency to sleep, and increased frequency and diminished tension of the pulse. On the other hand, when an infusion of the dried leaves was employed, the pulse fell from 80 to 69 in 3 hours (Van de Warker, *Criminal Abortion*, 1872).

Medical Uses.—Rue was held in high esteem from the time of Hippocrates. It was employed to cure amenorrhœa, promote the lochia, and cause abortion. It was believed that in women it stimulated sexual desire, but that in men it diminished the seminal secretion and the tendency to venery; that it was carminative and tonic, and useful internally and externally to relieve colic; and that it destroyed intestinal worms and cured intermittent fever. It was thought, in due proportion, to strengthen, but in excess to weaken, the sight, and was prescribed as an antidote to poisoning by aconite, mushrooms, etc. Externally, it was known to cause a pustular eruption upon the hands of persons employed to gather it, and was used to destroy fleas.

Rue is a powerful anti-spasmodic, and was formerly administered in enemata for preventing or shortening hysterical attacks. Its stimulant action upon the uterus is shown in the unimpregnated as well as the pregnant state of the organ, but especially in the cure of amenorrhœa due to non-inflammatory causes. In cases arising from congestion of the uterus, rue has sometimes occasioned profuse hæmorrhage and severe pain. It should, therefore, be cautiously used in dysmenorrhœa. In Chili it is said to be applied to the umbilicus and to the soles of the feet to produce an emmenagogue effect. The essential oil is the most convenient form for its administration. Rue has been used instead of savin in uterine hæmorrhage after abortion and when it depends upon general debility. A decoction of the fresh leaves of rue has been employed as an injection to destroy *ascari-ides* of the rectum, and internally to remove *lumbricoid* worms. Externally, compresses saturated with a strong decoction of the plant, and applied to the chest, have been used with advantage in chronic bronchitis. A similar decoction has been found very efficient in destroying body lice, in various scaly eruptions, and in glandular engorgements.

The decoction and infusion of rue should be made from the fresh plant, but as this is not always to be procured, the oil may be substituted for it in the dose of from 1 to 5 drops. An infusion may be prepared with about $\frac{1}{2}$ ounce of the leaves to a pint of water (Gm. 16 in Gm. 500).

SABADILLA, Br.—CEVADILLA.

Fructus (Semen) sabadille.—Cévadille, Fr.; Sabadillsamen, Läusekörner, G.

The seeds of *Veratrum Sabadilla*. *Schlechtendal*, s. *Asagraea* (*Helonias*, *Don*) *officinalis*, *Lindley*. *Sabadilla officinarum*, *Brandt*, *Schönocaulon officinale*, *Gray*. Bentley and Trimmen, *Med. Plants*, 287.

Nat. Ord.—Melanthaceæ.

Origin.—The cevadilla is a bulbous plant with long, linear, grass-like radical leaves and a slender scape, bearing a narrow spike-like raceme about 12 or 18 inches (30–45 Cm.) long of greenish-yellow flowers, of which the lower ones only are fertile. It is indigenous to the eastern section of Mexico, also to Guatemala and Venezuela. The plant growing in the latter country differs in some respects from the Mexican cevadilla, but no difference is observed in the seeds. The seeds alone are usually exported from Venezuela, and the ripe capsules from Mexico.

Description.—The fruit consists of three slightly-spreading, brownish, papery foli-
 FIG. 242.

 cles which are about $\frac{1}{2}$ inch (12 Mm.) long, and are either empty or contain from two to six seeds each. These are from $\frac{1}{4}$ to $\frac{1}{2}$ inch (5–8 Mm.) long, narrow oblong or lance-linear, one side usually flattened and angular, the lower end rounded and the apex attenuate and rather beaked; the testa is rugosely wrinkled, somewhat shining, of a brownish-black color, and encloses a whitish oily albumen and at the base a small linear embryo. The seeds are inodorous and have a bitter and persistently acrid taste; the powder is sternutatory.

Asagraea officinalis, *Lindley*: fruit, nat. size; seed and longitudinal section magnified.

Constituents.—Pelletier and Caventou's analysis (1820) proved the presence of fat, wax, mucilage, and *veratrine*, combined with an acid which was at first supposed to be gallic acid, but was shown by Pfaff to be a different compound; the fat is a mixture of liquid and solid fat, and contains a volatile fatty acid, *sabadillic* or *cevadilic acid*, which has an odor similar to that of butyric acid, melts at 20° C. (68° F.), and at a higher heat sublimes in white pearly needles. *Veratrine* was discovered by Meissner (1819). (For recent investigations on the alkaloids of *sabadilla* see VERATRINA.)

Veratric acid, $C_9H_{10}O_4$, was discovered by Merck (1839); it crystallizes in needles or prisms which are soluble in alcohol and hot water, but insoluble in ether, is fusible and

sublimable, and yields with the alkalies crystallizable salts which are soluble in alcohol and water.

Cevadilla yields about $\frac{1}{3}$ per cent. of veratrine and about $\frac{1}{60}$ per cent. of veratric acid. The composition of the capsular integuments has not been ascertained. The seeds are used in pharmacy only for preparing veratrine.

Medical Action and Uses.—The medicinal virtues of cevadilla are due to the veratrine it contains, and will be found more particularly described in connection with that alkaloid. The seeds are poisonous to dogs and cats, causing vomiting and convulsions. Two children drank of a decoction of cevadilla (?), and presented the following symptoms: vomiting, insensibility, pallor, a small sharp pulse, heat of head and cool extremities, and spasms of the face and limbs; deglutition was impossible, the pupils were dilated, and the eyes projecting and oscillating. Both patients recovered.

It was formerly employed to destroy body *lice* and other *vermin*, but sometimes, when applied to the sore head, it has occasioned alarming symptoms. The tincture has been found a very efficient remedy for *scabies*. The powder has been used for the same purpose, mixed with oil and brandy, and applied after the patient had taken a prolonged warm bath. Cevadilla has also been prescribed as a *vermifuge* for tænia and rectal ascariides, and for various nervous affections. It is seldom given internally, but the dose of the seeds is stated to be from 2 to 4 grains (Gm. 0.10–0.20).

SABBATIA.—SABBATIA.

American centaury, E.; *Centauree américaine*, Fr.; *Sabbatie*, G.

The herb of Sabbatia (Chironia, *Linné*) *angularis*, *Pursh*.

Nat. Ord.—Gentianaceæ.

Description.—The American centaury is a smooth biennial herb growing in dry fields and on hillsides throughout the Middle and Southern United States. Its stem is about 2 feet (60 Cm.) high, quadrangular, winged, and much branched above; the leaves are about an inch (25 Mm.) long, oblong-ovate, five-nerved, entire, acute, and at the base clasping; the flowers are in terminal corymbose panicles, have a five- or six-parted calyx with lance-linear lobes, a wheel-shaped pale or purplish-red corolla, about $1\frac{1}{2}$ inches (38 Mm.) wide, five or six finally recurved stamens, and produce an oblong-ovate, mucronate, many-seeded capsule. It blooms in July, and should then be collected. The herb is without odor, but has a persistent and purely bitter taste.

Constituents.—The plant contains the principles commonly found in herbs, but appears to be free from tannin, or nearly so; the bitter principle has not been obtained in a pure state. Méhu (1868) isolated *erythrocentaurin*, $C_{27}H_{24}O_8$, by agitating the syrupy alcoholic extract of European centaury with ether; it crystallizes readily, is inodorous, tasteless, neutral, readily soluble in carbon disulphide, benzol, and oils, and dissolves in 1600 parts of cold water, 48 parts of alcohol, 13 of chloroform, and 245 parts of ether; light colors it red, but on recrystallization it is again obtained colorless. The yield is only $\frac{1}{30}$ per cent. Méhu obtained (1870) the same principle also from *Erythræa chilensis*, *Persoon*, and J. F. Huneke (1871) from American centaury.

Pharmaceutical Preparation.—EXTRACTUM CENTAURII, Extract of centaury. It is made by digesting European centaury with hot water and evaporating the infusion.

Allied Herbs.—SABBATIA ELLIOTTII, *Stendel*, is known in Florida as *quinine-flower*. The stem is 10 to 20 inches (25–50 Cm.) high, terete and diffusely branched; the leaves are sessile, $\frac{1}{4}$ to $\frac{1}{2}$ inch (6–12 Mm.) long, obovate or oblanceolate, and the upper ones linear; the calyx-lobes are almost filiform and about one-fourth the length of the rose-colored corolla. The plant is inodorous and has a persistent, purely bitter taste. The solution of the alcoholic extract in acidulated water gives with potassio-mercuric iodide a slight precipitate (T. F. Beckert, 1877).

Several other species of Sabbatia, having white, rose-colored, or purplish flowers, are indigenous to the United States, particularly in the Southern States, and appear to possess similar properties.

ERYTHRÆA (GENTIANA, *Linné*) CENTAURIUM, *Persoon*: Herba centaurii, *P. G.*—European centaury. E.: Centauree, *Fr.*; Tausendguldenkraut, *G.*—This species closely resembles American centaury, but has oval or obovate-oblong, obtuse, three or five-nerved, nearly sessile leaves, and the parts of the flowers in fives. It is only 10 or 12 inches (25–30 Cm.) high, and grows spontaneously in a few places in this country.

PLEUROGYNE ROTATA, *Grisebach*, is a very bitter Japanese plant, with narrow linear-lanceolate leaves about 1 inch (25 Mm.) long, and pale-pinkish striped flowers, having the throat of the corolla bearded and the sessile stigmas prolonged on the valves of the ovary.

Medical Action and Uses.—American centaury is a simple bitter, without special

virtues. Its cold infusion is useful in debilitated states of the stomach, and its hot infusion as a diaphoretic in muscular *rheumatism*, *sore throat*, and febrile attacks generally. The infusion may be made with an ounce of the plant to a pint (Gm. 32 to Gm. 500) of boiling water, and given hot in the *dose* of from 4 to 6 fluidounces (Gm. 124–190), or cold in the *dose* of 2 fluidounces (Gm. 64).

SABINA, U. S.—SAVIN (SAVINE).

Sabinæ cacumina, Br. : *Summitates (Herba) sabinæ*, P. G.—*Savin-tops*, E. ; *Sabine*, Fr. ; *Sadebaumspitzen*, *Sevenkraut*, G.

The tops of *Juniperus Sabina*, *Linne*, s. *Sabina officinalis*, *Gærcke*. Bentley and Trimen, *Med. Plants*, 254.

Nat. Ord.—Coniferæ.

Origin.—Savin is a small evergreen procumbent or erect shrub which grows on rocky banks from Maine to Wisconsin, near the Great Lakes and farther northward. It is distributed throughout a great portion of Europe and eastward to the Caspian Sea and Southern Siberia. Besides in size, it is distinguished from red cedar (see page 851), which it closely resembles, by the larger fruit, which is nodding on the recurved peduncle-like branchlet. The young branchlets are collected for medicinal use.

FIG. 243.

Branch of Savin.

Description.—As met with in commerce, savin is in small and thin subquadrangular pieces, consisting of slender twigs, which are densely covered with minute, scale-like, imbricate leaves, arranged alternately in opposite pairs. The leaves are rhomboid-lanceolate, rather obtuse, and closely appressed, and on the back have a shallow groove containing a gland, which is mostly oblong in shape. Older leaves are more pointed and more or less spreading. Savin has a persistent somewhat terebinthinate odor, which is stronger after bruising the branchlets; the taste is nauseous, resinous, and bitter. The drug is frequently mixed with some fruits which are about $\frac{1}{2}$ inch (5 Mm.) in

diameter, globular, but more or less shrivelled, blackish-blue or brownish, contain usually two seeds, and have a similar but stronger odor and taste than the branchlets.

Constituents.—Gardes (1837) found savin to contain tannin, resin, volatile oil (page 1084), extractive, chlorophyll, etc. The fresh fruit yields 10 per cent. of volatile oil.

Off. Prep.—Ceratum (Unguentum) sabinæ, U. S., Br. ; Extract. sabinæ fluid., U. S. ; Tinctura sabinæ, Br.

Medical History.—In ancient times the virtues of savin were clearly recognized. Its stimulant action caused it to be employed for the treatment of ulcers and carbuncles and as a remedy for alopecia; it was also used with honey for the removal of freckles; and it was well known that, internally, it was apt to cause bloody urine, and, when taken by pregnant females, miscarriage.

Physiological Action.—Given to dogs in powder, it occasions severe pain, vomiting, bloody stools and urine, paralysis, spasms, and death; after which evidences are found of gastro-intestinal inflammation and the brain is congested. The oil of savin produces similar but more intense effects. (See OLEUM SABINÆ.) On man the action of savin itself is chiefly illustrated by cases in which it was taken for the purpose of producing abortion. Thus, an infusion caused incessant vomiting, abortion, excruciating pain, rupture of the gall-bladder, and death. Many cases are recorded of the fatal consequences of its use in large doses.

Medical Uses.—Savin has been used with unquestionable advantage in cases of *amenorrhœa* and *dysmenorrhœa* depending on a want of vigor in the uterine apparatus, and also for the cure of *menorrhagia* depending upon a like condition. Several trustworthy physicians declare that in such cases of uterine hæmorrhage 1 grain of powdered savin, repeated three times a day and continued for weeks together, will overcome the tendency to the uterine loss. Under like conditions *sterility* and *chlorosis* have been cured by this medicine. For *amenorrhœa* it has been recommended to administer a pill composed of rue, savin, and ergot, of each 1 grain, and aloes $\frac{1}{2}$ grain, three times a day at first, and gradually increasing the dose (Courty). It had once a repute, not entirely undeserved, for its virtues in *chronic gout* and *rheumatism*, for which it was employed in

infusion or in decoction, both internally and in a lotion for the affected joints. Savin has no doubt been found efficient as a *vermifuge*, but other anthelmintics are to be preferred as being less dangerous. In pregnancy, and whenever there is a tendency to congestion of any important organ, savin is contraindicated. Savin, in cerate, is used to excite or to prolong the secretion produced by blisters. Its powder, slightly moistened, is one of the most efficient remedies for *venereal warts*. It may be applied alone or mixed with burnt alum or with subacetate of copper. It is also used, either in powder or in solution, to wither *polypi*, and may be applied with advantage to *condylomata*, and, as in ancient times, to stimulate indolent and unhealthy *ulcers*.

Fresh is much more active than dried savin. It may be administered in powder in the *dose* of 5 to 6 grains (Gm. 0.30–0.40), repeated several times a day. It is most conveniently given in syrup or honey.

SACCHARUM, U. S., P. G.—SUGAR.

Saccharum purificatum, Br.—*Refined sugar, Cane-sugar*, E.; *Sucre, Sucre de canne*, Fr.; *Zucker, Rohrzucker*, G.

The refined sugar of *Saccharum officinarum*, *Linné*. Bentley and Trimen, *Med. Plants*, 298 (nat. ord. Graminaceæ). Formula $C_{12}H_{22}O_{11}$. Molecular weight 342.

Origin.—The sugar-cane appears to have been indigenous to India and other parts of Southern and Eastern Asia, and has been cultivated from time immemorial. At present it is not known in the wild state, but it is raised in most tropical and subtropical countries, and in many of them for the production of sugar. It is a perennial, and produces a stem which is from 8 to 12 feet (2.4–3.6 M.) high, 1 to 2 inches (2–5 Cm.) thick, cylindrical, jointed, and, with the exception of the flowering tops, which are hollow, filled with a juicy pith. The leaves are 4 to 5 feet (1.2–1.5 M.) long, 2 inches (5 Cm.) wide, and linear; and the flowering panicles large, pyramidal, and with spreading branches. Several varieties are known, differing chiefly in the color and hairiness of the stem. *Saccharum chinense*, *Roxburgh*, having a slender, erect panicle, is probably a distinct species, and the one principally cultivated in China.

Cane-sugar is present in a large number of grasses, particularly in those having a rather thick stem, such as *Sorghum saccharatum*, *Persoon*, s. *Holcus saccharatus*, *Linné*, *Zea Mays*, *Linné*, and others. From the thorough researches of H. Leplay, published in 1882, it appears that in maize the sugar is produced in the leaves and transferred to the stem, where it gradually accumulates, and when the fruit begins to develop it is conveyed to the grain, where it is converted into starch, the sugar at the same time disappearing from the leaves and diminishing very materially in the stem. It is also present in the juice of different species of maple, birch, palm, and other trees, and in many fleshy roots, prominent among which is a cultivated variety of *Beta vulgaris*, *Linné*, or *sugar-beet*, which is largely employed in Europe in preparing sugar.

Preparation.—Recently-collected sugar-cane yields by crushing and expressing about 80 per cent. of juice, which contains from 78 to 84 per cent. of water, 16 to 21 per cent. of sugar, 0.3 to 0.4 per cent. of mucilaginous, resinous, fatty, and albuminous matters, and nearly the same amount of salts. The juice is a grayish, turbid, sweet liquid, which is clarified by heating, a little lime being at the same added for the purpose of neutralizing free acid; it is then concentrated by rapid evaporation in open pans, transferred to coolers, where it is frequently stirred, and afterward into casks perforated at the bottom and arranged in such a manner that the liquid portion may drain off and be collected in suitable tanks. The granular solid product thus obtained constitutes the *raw* or *muscovado sugar* of commerce; the liquid portion is known as *treacle* or *molasses*. Raw sugar is refined by dissolving it in water, the solution is heated with blood, the impurities are skimmed off, and the liquid is filtered through recently-burned granular animal charcoal. The clear and colorless filtrate is concentrated in a vacuum-pan, and when of sufficient density run off into conical moulds, the narrow orifice of which is closed by a plug. It solidifies as a dense crystalline mass, which is drained by the removal of the plug, and freed from the remaining colored mother-liquor by percolating through it a concentrated solution of pure sugar, after which it is dried and sent into commerce as *refined* or *loaf sugar*. By concentrating the mother-liquors they are made to yield more sugar of an inferior grade, until finally a thick syrupy liquid is obtained, which refuses to crystallize, and is known as *sugar-house molasses*, and in England as *treacle*.

The method of obtaining sugar from the sugar-beet is very similar to that described, but is attended with greater difficulties, owing to the presence of larger quantities of

proteids and other foreign constituents. Sugar-beets contain about 12 per cent. and yield about 9 per cent. of cane-sugar.

Properties.—Refined sugar is seen in commerce broken into small pieces or lumps, which are hard and have a granular crystalline texture and a pure white color. Some-what inferior kinds of sugar are softer, and those having a yellowish tint are often artificially improved in appearance by adding, while crystallizing, a minute quantity of blue pigment, like ultramarine, with the view of neutralizing the objectionable tint and making the sugar appear whiter; such sugar will yield a yellowish solution with water, and on standing will gradually separate the pigment. Perfectly white sugar, known in commerce as *double refined*, is the only kind that should be used in pharmaceutical preparations. Sugar may be obtained in large transparent rhombic prisms, known as *rock candy*, *saccharum candidum*, which does not differ from lump sugar except that this is in crystalline masses from disturbed crystallization. Sugar has the specific gravity 1.58 (Kopp), is permanent in the air, neutral, without odor, has a very sweet taste, and dissolves at ordinary temperatures in one-half its weight of water, yielding a dense, sweet, and colorless liquid known as syrup; saturated at 15° C. (59° F.), such a solution contains 66 per cent. of sugar, and this has the density 1.345082 (Michel and Kraft). At the boiling-point sugar dissolves in water almost in all proportions (in 0.2 parts, *U. S.*; 0.212 parts, *Flourens*). It requires for solution about 80 parts of boiling absolute alcohol, 28 parts of boiling officinal alcohol, and about 4 parts of boiling alcohol spec. grav. .830, these solutions depositing most of the sugar on cooling. The solubility is greater in weak alcohol, both cold and hot. At 15° C. (59° F.) 1 part of sugar dissolves in 2 parts of 50 per cent. alcohol, in 7.7 parts of 75 per cent. alcohol, in 14.7 parts of 80 per cent. alcohol, in 31.6 parts of 85 per cent. alcohol, in 175 parts of 92 per cent. alcohol, and in 228 parts of methylic alcohol of the same strength (*Casamajor*). Sugar dissolves also in glycerin, the solubility being increased on dilution with water, but it is insoluble in ether, chloroform, carbon disulphide, and in hydrocarbons. It combines with chloride of sodium, yielding deliquescent crystals which contain 14.9 per cent. of that salt. Definite compounds have likewise been obtained with several other salts and with alkalies and alkaline earths. (See *SYRUPUS CALCIS*.) When triturated in the dark it becomes luminous. Its solution deviates polarized light to the right—a behavior which is of great practical importance for the estimation of sugar in aqueous liquids and for distinguishing different kinds of sugar, which have a different rotary power.

When sugar is heated to 160° C. (320° F.) it melts without losing in weight, and congeals on cooling to a transparent amorphous yellowish mass known as *barley sugar*, *saccharum hordeatum*, which becomes gradually opaque on the surface from the formation of minute crystals. If sugar is kept in the melted state between 160° and 170° C. (320° and 338° F.) for a short time, it is converted into a deliquescent mixture of *glucose* and *levulosan*; $C_{12}H_{22}O_{11}$ yields $C_6H_{12}O_6 + C_6H_{10}O_5$; the latter is not fermentable until after it has been boiled with water or dilute acids. When heated to between 180° and 200° C. (356° and 392° F.) sugar turns brown, evolves a peculiar odor, and is converted into *caramel*, $C_{12}H_{18}O_9$, parting at the same time with $2H_2O$; the pure product of this composition, *caramelan*, was obtained colorless by *Gélis* (1862). Caramel may be prepared in the same manner from inferior qualities of sugar, from molasses, and from glucose, and the conversion is hastened in the presence of small quantities of alkalies; the addition of a little carbonate of ammonium, which is again volatilized by the heat, is of service, for the reason stated. Subjected to dry distillation, sugar yields aldehyd, acetone, acetic acid, tarry products, and carbonic acid, carbonic oxide, and marsh gas. According to *Lassaigne*, iodine heated with solution of sugar is converted into hydriodic acid. Under the influence of ferments, as well as of dilute acids, cane-sugar is converted into *invert-sugar*, which is a mixture of *dextrose* or grape-sugar and *levulose* or fruit-sugar, and is directly fermentable. This inversion of sugar takes place slowly on boiling with water, but cold aqueous solutions keep unaltered for a long time, provided the access of ferments suspended in the air be prevented. Under the same condition, according to the investigations of *Kreusler*, *Lemoine*, and others, light does not exert the inverting effect reported by *Raoul* (1871). Nitric acid inverts cane-sugar readily, and when heated with it produces saccharic, racemic, tartaric, and oxalic acids.

Tests.—The purity of cane-sugar is ascertained by the physical properties described above, and by its complete solubility in water and alcohol. The absence of glucose or of a similar sugar is ascertained by some of the reactions given below. "Aqueous and alcoholic solutions of sugar should have no effect on litmus-paper. The solution in 20 parts of distilled water should be scarcely rendered turbid by silver nitrate or barium nitrate

(chloride and sulphate).”—*P. G.* “Neither an aqueous nor an alcoholic solution of sugar kept in large, well-closed, and completely-filled bottles should deposit a sediment on prolonged standing (absence of insoluble salts, foreign matters, ultramarine, Prussian blue, etc.). If a portion of about 1 Gm. of sugar be dissolved in 10 Ccm. of boiling water, then mixed with 4 or 5 drops of test solution of nitrate of silver and about 2 Ccm. of water of ammonia, and quickly heated until the liquid begins to boil, not more than a slight coloration, but no black precipitate, should appear in the liquid after standing at rest for 5 minutes (absence of grape-sugar and of more than a slight amount of inverted sugar).”—*U. S.*

ELÆOSACHHARA, Oil sugars. Volatile oil 1 drop, sugar 2 Gm.; mix.—*P. G.*

Other Sugars.—GLUCOSE, GRAPE-SUGAR, DEXTROSE, or STARCH-SUGAR, $C_6H_{12}O_6$; molecular weight 180. Hydrated, $C_6H_{12}O_6 \cdot H_2O$; mol. weight 198. Carbohydrates having a sweet taste are frequently met with in plants and among the products of decomposition of those organic compounds forming the large class of *glucosides*. The sugar yielded by the latter is frequently, though not always, identical with the sugar met with in grapes and other fruits and with that produced from starch. This is now very largely made for uses in the arts by boiling 100 parts of starch, 400 parts of water, and 4 or 5 parts of sulphuric acid until starch can no longer be detected in the liquid, the transformation being hastened by heating under pressure; the free acid is then neutralized with chalk, the filtrate clarified and decolorized, if necessary, by treating it with clay and animal charcoal, and, finally, concentrated, preferably in a vacuum-pan. The grape-sugar or glucose of commerce is prepared in this manner. Liquid glucose contains from 34 to 43 per cent. of dextrose, from 0 to 19 per cent. of maltose, from 30 to 45 per cent. of dextrin, and from 14 to 23 per cent. of water. Solid grape-sugar is usually in a white or whitish, irregularly granular powder or mass; from alcohol it may be obtained in compact, nodular groups of needles. A. Behr (1882) has shown that the cooling concentrated solution of glucose, on the addition of crystals or powdered crystals of that compound, will give a large crop of prisms of anhydrous glucose. It rotates polarized light to the right, though less than cane-sugar, reduces the so-called noble metals, and acquires a dark color when heated with solutions of alkalis. It is less sweet than cane-sugar, is directly fermentable, undergoes by heat alterations analogous to those of cane-sugar, is insoluble in ether, dissolves in about 50 parts of alcohol, and requires little more than 1 part of cold water for solution; but after it has been rendered amorphous by heat it dissolves in water in nearly all proportions. Nitric acid oxidizes it to saccharic, tartaric, racemic, and oxalic acids. *Saccharic acid*, $H_2C_6H_8O_8$, is amorphous, deliquescent, freely soluble in water and alcohol, and yields mostly crystallizable salts.

LEVULOSE, CHYLARIOSE, or FRUIT-SUGAR, $C_6H_{12}O_6$; mol. weight 180. It frequently accompanies grape-sugar in fruits, also in honey; in some plants it is associated with cane-sugar. It is usually a colorless, uncrystallizable syrup, has nearly the same sweetness as cane-sugar, and turns the plane of polarized light to the left. It may be obtained in fine silky needles which are insoluble in absolute alcohol and ether, but dissolve readily in aqueous liquids. Levulose is produced from inulin by treatment with dilute acids; with nascent hydrogen it yields mannit. Among the products of oxidation by nitric acid are succinic, acetic, and oxalic acids.

INOSIT, PHASEO-MANNIT, $C_6H_{12}O_6 \cdot 2H_2O$; mol. weight 216. It is present in the juice of some meats, in the green fruit of many Leguminosæ, in asparagus, and in other plants. It is very sweet, crystallizes readily from water and alcohol, is insoluble in ether, does not undergo alcoholic fermentation, and yields with nitric acid explosive compounds and oxalic acid.

Sugar Tests.—*Moore's Test.* A solution of cane-sugar, heated with 3 or 4 per cent. of potassa for a minute or two, remains colorless; glucose and milk-sugar are colored brown.

Trommer's Test. A solution of cane-sugar, mixed with a little sulphate of copper and an excess of potassa or soda, retains its blue color on boiling, but turns bright-red in the presence of glucose or milk-sugar, red cuprous oxide being deposited. Glucose and most allied sugars effect the same reduction, though more slowly, in the cold.

Fehling's test is a modification of the preceding, and may be used for the quantitative determination of glucose. The test liquid is prepared by dissolving 34.64 Gm. of crystallized sulphate of copper in water, adding 200 Gm. of Rochelle salt, and 600 or 700 Gm. of soda solution spec. grav. 1.20, and diluting the whole to 1 liter (Schorlemmer). 10 Ccm. of this solution are reduced by 0.5 Gm. of grape-sugar. Boedeker introduced Rochelle salt in place of potassium tartrate, which was used by Fehling. The test is usually made with a solution containing about 1 per cent. of glucose; weaker solutions reduce a somewhat smaller amount of the test liquid.

Pettenkofer's Test. Bile in the presence of sugar (of other carbohydrates and of proteids) acquires a blood-red color with concentrated sulphuric or phosphoric acid.

Boettger's Test. A little subnitrate of bismuth, boiled with solution of glucose, rendered alkaline by sodium carbonate, acquires a gray or black color; pure cane-sugar produces no alteration.

O. Schmidt's Test. Acetate of lead, added to a saccharine liquid, is precipitated white by

excess of ammonia; on heating the mixture it remains unchanged if cane-sugar or milk-sugar is present, but turns orange-red with glucose.

Sachsse's Test. 18 Gm. mercuric iodide, 25 Gm. potassium iodide, and 80 Gm. caustic potassa are dissolved in distilled water sufficient to make 1 liter. 40 Ccm. of this solution heated to boiling are decomposed by 1.1342 Gm. of glucose, so that a drop of the liquid is not rendered black by sulphhydrate of ammonium.

Mauenné's Test. On heating a solution of glucose with a few drops of solution of silver nitrate the liquid acquires a brown color.

Tollen's Test. An ammoniacal solution of silver nitrate containing caustic soda is reduced by glucose, with the production of a metallic mirror.

Gawalewski's Test. A solution of sugar heated with neutral ammonium molybdate to 100° C. (212° F.) becomes blue in the presence of glucose.

Many other tests have been proposed; the above are quite available and give good results. Tannin and similar compounds which are likely to interfere are previously removed, either by solvents or precipitants.

History.—Cane-sugar has been manufactured in Asia from the most remote antiquity. "Thou hast bought me no sweet cane with money" (Isa. xliii. 24), in the eighth century before Christ, seems to be an allusion to the sugar-cane. In the fourth century before our era Theophrastus wrote of a sort of "honey" procured from canes or reeds. In the first century several writers allude to it, and describe its origin as Oriental; but for more than a thousand years it remained unknown in Europe, when it was introduced by the Arabians, along with the arts and sciences of which they were the surviving depositaries. From the Mediterranean countries it was transplanted to the New World, which was destined to return the gift with interest, but it is only within the last two or three hundred years that its use became general as an article of food.

The medicinal virtues of sugar were alleged by the ancients to be that it is laxative, and cleansing to inflamed and ulcerated surfaces, and is less apt than honey to excite thirst. When, in course of time, it came into general use, it was accused of impairing the digestion, producing biliousness, promoting the generation of intestinal worms, and causing caries of the teeth—opinions every one of which is popular at the present day. Sugar is generally regarded as nutritious food, contributing directly to the growth of the tissues, and especially to the formation of fat. But a more thorough experimental investigation of the subject has shown that sugar cannot be regarded as nutritious. On the contrary, an excessive consumption of it leads to wasting of the tissues and a scorbutic condition. Its real value as an article of food appears to be that it diminishes tissue-waste, and that in so far, therefore, it resembles alcohol and oil in its mode of action.

Medical Uses.—Sugar is of comparatively little value for its independent effects, but few substances are more useful as an associate of other medicines, whether to preserve them from oxidation and decomposition, to conceal or improve their taste, or to give them special pharmaceutical forms.

In solution sugar is almost exclusively lenitive, but in powder it is stimulant. It is universally employed to diminish dryness of the mouth and fauces, to allay irritation, and to mitigate *cough* and *hoarseness*. Sugar dissolved in water is said to have a diuretic effect. When injected into the veins of animals it is said to be powerfully diuretic (Richet and M. Martin, *Med. Record*, xxi. 394.) It certainly, when moderately used, promotes digestion and allays nervous excitement. For these purposes sweetened water (*eau sucrée*) is universally employed in France and Southern Europe. Formerly a strong solution of sugar was much used as an antidote to *corrosive poisons*. It enters into all the drinks, mucilaginous, farinaceous, and gelatinous, employed in febrile diseases. Finely-powdered sugar will sometimes relieve the *hiccough* which in nursing infants is apt to arise from over-feeding. Loaf-sugar, eaten freely, is said to arrest the development of *alcoholic intoxication*, perhaps by retarding gastric absorption. A strong solution of sugar injected into the rectum has been used successfully to destroy *ascarides* of that part. In powder it is very efficient as a remedy for *aphthæ* of the mouth, in repressing the exuberant and stimulating the indolent granulations of *ulcers*, in removing opacities of the *cornea*, and in curing granular *eyelids*. Sugar has been claimed by Fischer to be an efficient antiseptic dressing for *wounds*. He associated it, however, with other antiseptics; but Windelschmidt states that for small wounds sugar is equal to iodoform as a dressing (*Med. News*, xliii. 462). In *chronic laryngitis*, when inhaled by a sudden aspiration from a tube extending to the root of the tongue, it may be used with advantage alone or mixed with other powders. In the same manner it may be employed as a snuff in chronic *ozæna*. The fumes from burnt sugar destroy *offensive effluvia*, and are conveniently disengaged by sprinkling sugar upon burning coals or on a hot shovel.

The culinary and medicinal uses of beet-sugar are the same as those of cane-sugar, but in sweetness it is inferior.

SACCHARUM LACTIS, *U. S., Br., P. G.*—SUGAR OF MILK.

Lactose, Milk-sugar, E.; Sucre de lait, Lactine, Fr.; Milchsücker, G.

A crystalline sugar prepared from the whey of cow's milk.

Formula $C_{12}H_{22}O_{11} \cdot H_2O$. Molecular weight 360.

Preparation.—Milk-sugar is one of the constituents of the milk of mammals, and appears to be present in larger proportion in the milk of herbivorous animals than in that of the Carnivoræ. To obtain it, the butter and casein are first removed, the whey (see p. 861) is concentrated, and the liquid permitted to crystallize in large tanks, the crystallization being facilitated by the introduction of thin sticks or cords; the impure crystals are once or twice recrystallized from water. It is chiefly prepared in Switzerland. About 100,000 pounds of milk-sugar are annually imported by the United States. Milk-sugar was prepared by Bertoletti in 1619, and was introduced into medicine by Testi in 1698.

Properties.—Sugar of milk is usually met with in commerce in cylindrical pieces composed of numerous crystals aggregated around an axis of stick or cord. It crystallizes in hard white or translucent four-sided prisms, is permanent in the air, yields a white sandy powder, is neutral, inodorous, and has a slightly sweet taste. It dissolves in 6 parts (7 parts, *U. S., P. G.*) of water at 15° C. (59° F.), and in 1 part (Guérin-Varry), or, according to other observers, in 2½ parts, of boiling water, and is insoluble in ether, chloroform, and hydrocarbons. Its aqueous solution rotates the plane of polarized light to the right, is rendered yellow or brown on being heated with solutions of alkalies or alkali carbonates, reduces in the cold, or more rapidly on heating, alkaline liquids containing salts of copper, bismuth, mercury, or silver, and produces a bright metallic mirror with ammoniacal solution of silver. When heated to 130° C. (266° F.) milk-sugar parts with its water of crystallization without fusion, and leaves a white mass which again absorbs water, at a higher heat becomes yellow, and melts at 203.5° C. (398° F.) (Lieben); but above 170° C. (338° F.) it is converted into *lacto-caramel*, $C_6H_{10}O_5$, and afterward into products similar to those obtained on the dry distillation of cane-sugar and glucose. Milk-sugar does not readily undergo vinous fermentation until after it has been boiled with diluted sulphuric acid, which converts it into *galactose*, $C_6H_{12}O_6$, and glucose. In the presence of casein it is converted into *lactic acid* (see page 71), alcohol being formed at the same time, but in small quantity only if the free acid is neutralized as fast as it is produced. By boiling with dilute nitric acid it is converted into mucic, saccharic, tartaric, racemic, and finally into oxalic, acid. Its hardness renders it serviceable for reducing other substances to a fine powder.

Tests.—If 1 part of sugar of milk be sprinkled upon 5 parts of sulphuric acid contained in a flat-bottomed capsule, the acid should acquire at most a greenish or reddish, but no brown or brownish-black, color within 1 hour (absence of cane-sugar).—(*U. S., P. G.*) It is important that in applying this test heat be avoided, since milk-sugar is rendered dark-brown by concentrated sulphuric acid at the heat of the water-bath. "On adding 0.2 Gm. of milk-sugar to a boiling mixture of 4 Gm. of solution of basic lead acetate and 2 Gm. of ammonia-water, a white precipitate free from a red tint should be produced (absence of glucose)."—*P. G.*

Off. Prep.—Triturations, *U. S.*

Medical Action and Uses.—Sugar of milk is far less sweet than cane- or beet-sugar, and is thought to be less apt to ferment in the stomach and bowels. It is chiefly used as a vehicle for small doses of pulverulent medicines. It is said that added largely to warm skimmed milk it may be used as a laxative (*Bull. de therap.*, cii. 182).

SALEP.—SALEP.

Tubera (Radix) salep, P. G.—Salep, Fr., G.

The tubers of different species of *Orchis* and allied genera.

Nat. Ord.—Orchidaceæ, Ophrydeæ.

Origin and Preparation.—The plants belonging to the genus *Orchis* are small herbs, usually with a stem between 6 and 18 inches (15–45 Cm.) high, with showy, mostly pink, red, or purple-colored ringent flowers, having the lip turned downward and bearing a nectariferous spur underneath, and with parallel-veined sheathing leaves, those

of the stem often reduced to bracts. The subterranean portion usually consists of two fleshy tubers, the smaller of which originates from the axil of a radical leaf and produces the flowering stem during the following year. These tubers furnish the salep. They are collected, scalded in water, and rapidly dried, and thereby lose their white opaque appearance, as well as their unpleasant odor and bitter taste. Salep was formerly procured in Persia and other Oriental countries from the tubers of *Eulophia campestris*, *E. herbacea*, *Lindey*, and several allied species. At the present time it is prepared in various parts of Southern and Central Europe. The German Pharmacopœia admits only unbranched tubers, such as are furnished by *Orchis mascula*, *Linne*, *O. Morio*, *Linne*, *O. ustulata*, *Linne*, *Anacamptis pyramidalis*, *Richard*, *Platanthera* (*Habenaria*, *R. Brown*) *bifolia*, *Reichenbach*, and other species.

Description.—Oriental salep is 1–1½ inches (25–40 Mm.) long, and usually dark-colored; European salep is always smaller. Salep is globular, pyriform, ovate, or oblong

in shape, somewhat flattened or wrinkled, with a scar of the terminal bud at the apex, of a pale brownish-yellow color, somewhat translucent, of a horny texture, hard, inodorous, and of an insipid, very mucilaginous taste. It is generally kept in the form of powder, which has a yellowish color. The tissue consists of thin-walled parenchyma filled with starch, the granules of which

FIG. 244.

Salep: tubers and transverse section.

are more or less ruptured from scalding, and of large, nearly globular cells containing mucilage. The scattered fibro-vascular bundles are small and thin, and few cells contain raphides.

The tissue of palmately-divided tubers is similar, but the mucilage-cells are generally much smaller and more or less elongated. Such tubers are derived from *Orchis latifolia*, *Linne*, *O. maculata*, *Linne*, *O. sambucina*, *Linne*, *Gymnadenia conopsea*, *R. Brown*, and other species, and were formerly known in European pharmacy as *radix palmæ Christi*. They are rather flat, below divided into two to five branches, and less mucilaginous, but otherwise resemble the former kind.

Constituents.—Raspail found the old tuber collected in autumn to be free from starch, while the young tuber contained then large quantities of it. Dragendorff (1865) obtained from 100 parts of salep starch 27.3, mucilaginous constituents 48.1, sugar 1.2, proteids 4.9, and cellulose 2.4, parts; the mucilage is not extracted by cold water. Salep yields 2.1 per cent. of ash.

Adulterations and Substitutions.—The scalded tuber of colchicum resembles salep in appearance, but has a broad groove on one side and a sweetish afterward bitter and acrid taste. An adulteration of powdered salep with starch is best detected by the microscope, which reveals the shape of the foreign starch-granules; owing to the manner of its preparation, salep has its starch converted into a pasty mass. 1 part of powdered salep should yield, with 50 parts of boiling water, a jelly which after cooling is rather stiff, and with 100 parts a thick turbid mucilage; this has an insipid taste and is rendered blue by iodine.

MUCILAGO SALEP. *P. G.*, is prepared by shaking in a vial 1 part of powdered salep with 10 parts of cold water until it is uniformly diffused, when 90 parts of boiling water are added and the whole well agitated.

Medical Action and Uses.—Salep was, even in ancient times, regarded as very nutritious, and as a demulcent it was used in medicine. It tends to confine rather than relax the bowels, and hence is a very useful article of diet for infants and children affected with *diarrhœa* or *summer complaint*, and for adults suffering from tuberculous and other forms of chronic diarrhœa. The mucilage is prepared by first macerating powdered salep in cold water, and gradually adding boiling water, with stirring, in the proportion of 5 grains of salep to the ounce. Instead of water, milk or some animal broth may be used. Salep jelly may be made as follows: Rub 60 grains of powdered salep with water in a mortar until it has swollen to four times its original bulk; then add gradually, and with constant stirring, 16 ounces of boiling water, and boil down to 8 ounces.

SALICINUM, U. S., Br.—SALICIN.

Salicine, Fr.; *Salicin*, G.Formula $C_{13}H_{18}O_7$. Molecular weight 286.

Origin.—Salicin exists in the bark of most species of *Salix* and *Populus*, and to a small extent also in the leaves and pistillate flowers. According to Herberger, it is best prepared from the bark of young wood, which contains it in relatively larger proportion than the trunk-bark, and associated with smaller quantities of other compounds, which interfere with its isolation. It may also be prepared from populin by boiling it with lime-water or with solution of barium hydrate. Salicin was discovered by Leroux (1830); in the same year Braconnot obtained from it saligenin and saliretin, without, however, recognizing their relations to salicin; these and the glucoside nature of the latter were first established by Piria (1838, 1845). Herberger obtained 3 to 4 per cent. of salicin from the bark of *Salix pentandra* and *S. Helix*; but the results of different investigators with various species are very variable, which may in part be due to the kind of bark examined. This principle was prepared synthetically by A. Michael in 1879.

Preparation.—A decoction of willow-bark is deprived of tannin and coloring matter by digesting it with levigated litharge (Duflos) or by precipitating with basic lead acetate (Peschier); in the latter case the free acid is afterward neutralized with calcium carbonate. The filtrate on concentration yields crystals which require purification by recrystallization. The tannin may also be removed by milk of lime, and the salicin taken up by alcohol from the filtrate concentrated to a soft extract.

Properties.—Salicin crystallizes in colorless plates or flat rhombic prisms, but is usually seen in white glossy scales or needles. It remains unaltered in the air, has a neutral reaction to test-paper, is inodorous, and possesses a persistently bitter taste. Piria found it to be soluble in 30 parts of water at 11.5° C. (52.7° F.), and somewhat less freely in alcohol (30 parts, Hager). It dissolves in 0.7 part of boiling water and in 2 parts of boiling alcohol (U. S.), is soluble in amyllic alcohol, creasote, and without alteration in acetic acid, dissolves more freely in alkaline liquids than in water, but is insoluble in ether, chloroform, benzol, and petroleum benzin. Its ammoniacal solution is not colored on exposure (difference from phlorizin), and its aqueous solution is not precipitated by tannin or the various reagents for alkaloids. Salicin melts at 198° C. (388.4° F.) to a colorless liquid, which on cooling congeals crystalline; at a higher heat it becomes brown, at about 260° C. (500° F.) gives off acid vapors having the odor of salicylous acid and of caramel, and at a red heat is completely decomposed, without leaving any residue.

Cold sulphuric acid dissolves salicin with a bright-red color; after the absorption of water from the air—but not after the addition of water or after being neutralized by an alkali—deposits a red powder (*rutilin*) which after washing is yellowish-red, after drying blackish-brown, insoluble in water, alcohol, and glacial acetic acid, and is colored violet-red by alkalis (Braconnot). On warming salicin with somewhat diluted sulphuric acid and potassium bichromate, *salicylous acid* or *salicyl-aldehyd*, $C_7H_6O_2$, is given off, recognizable by its peculiar fragrance. Salicin is a glucoside, and when digested with emulsin or saliva, or heated to 80° C. (128° F.) with dilute sulphuric acid, assimilates 1 molecule of water and is split into glucose and *salicylic alcohol* or *saligenin*, $C_7H_8O_2$, which crystallizes in pearly tables, is easily soluble in hot water, alcohol, and ether, melts at 82° C. (179.6° F.), and sublimates at 100° C. (212° F.). Saligenin is characterized by yielding in solution a deep-blue color with ferric chloride, and when boiled with dilute acids by being converted into a resinous body, *saliretin*, $C_{14}H_{14}O_3$, while oxidizing agents convert it into salicylous and salicylic acids. Cold nitric acid of specific gravity 1.16 oxidizes salicin, with the production of *helicin*, $C_{13}H_{16}O_7$, which crystallizes in white needles, and is by ferments and dilute acids resolved into sugar and salicylic aldehyd. If nitric acid of spec. grav. 1.09 is employed, salicin yields *helicoidin*, $C_{26}H_{34}O_{14}$, which may be regarded as a compound of salicin and helicin. These interesting reactions have been chiefly investigated by Piria (1837, etc.).

Tests.—The behavior of salicin to ammonia distinguishes it readily from phlorizin, and its solubility in cold nitric acid from those alkaloids which acquire with this reagent a characteristic color. To test for poisonous alkaloids, which may possibly be present, Hager recommends agitating 0.2 Gm. of salicin with 4 Ccm. of water and 1 Ccm. of potassa solution, when a clear solution should be obtained. "The aqueous solution of salicin should not be precipitated by tannic or picric acid, nor by iodide of mercury and potassium (absence of, and difference from, alkaloids)."—U. S.

Physiological Action.—Salicin does not, like quinine, exert any marked influence in preventing or retarding putrefaction or fermentation; but when taken internally it has the same effect as salicylic acid in preventing the fermentation of urine in the bladder, because in the system it is converted into that acid. Injected under the skin of rabbits to the extent of 30 grains, it caused no toxic phenomena. Although it is related that some very sensitive persons after repeated doses of 3 or 4 grains complained of dimness of sight and flashes before the eyes, yet in others, when several ounces were taken in the course of three weeks, no disorders were occasioned except ocular scintillations and ringing in the ears. In one instance about 250 grains were administered within two days without any sensible effects. Very marked and singular phenomena were produced by four doses of 40 grains each, taken at intervals of two hours by a physician affected with rheumatism. They consisted of a succession of phantasmal illusions and musical delusions that lasted for 48 hours (*Boston Med. and Surg. Jour.*, Jan. 1884, p. 118).

The experiments of Ringer and Bury with salicin upon healthy children appear to show that it has no influence upon the temperature, and that under full medicinal doses a dusky flush suffuses the face on slight excitement, while the expression becomes dull and heavy. Less constant symptoms are deafness, noises in the ears, frontal headache, trembling of the hands, and quickened breathing. Very large doses occasion severe headache, marked muscular weakness, tremor, and irritability. Tingling may be felt in the extremities, and the voice becomes husky; the breathing is hurried, but there is no dyspnoea: large doses often repeated raise the pulse-rate to 140 and render the beats feeble. Other observers have noted an intermittent or a slower pulse among the physiological effects of this medicine, while the greater number declare that in healthy persons and in medicinal doses it does not affect the pulse at all. Such has certainly been the case after doses of 40, and even 75, grains, which produced buzzing in the ears and a state of semi-intoxication. In some cases it has caused vomiting and purging, and its continued use has occasioned gastric catarrh. A similar dissidence exists in regard to its influence upon the temperature in health. The singular opinion has been expressed that it is only sedative to the calorific function when it acts as a diuretic. On the whole, we repeat, there is no reason to believe that in healthy persons it reduces the temperature. Salicin appears to render the sweat alkaline or neutral even in rheumatic patients with acid urine, but the evidence of this operation is not conclusive. To its promotion of urinary elimination must be attributed its alleged action in removing yellowness of the skin in jaundice.

Medical Uses.—Salicin has been used, and indeed was first used, in the inflammatory affections in which it has since been customary to employ salicylic acid and its compounds. In the report of one physician (Riess), who vaunted the antiphlogistic virtues of this substance, the mortality from *pneumonia* is stated to have been 11 out of 35 cases—a result which is the reverse of encouraging. The experience of Dr. Greenhow in treating *rheumatic* fever with salicin was, on the whole, not so satisfactory as to encourage him in continuing to employ it (*Trans. Clin. Soc.*, xiii. 261). Conway vaunted its topical application in severe cases of *diphtheria*, but his success has not been matched (*Practitioner*, xxviii. 61). Many have reported salicin to be a valuable substitute for quinine, but these reports are counterbalanced by others, which appear to show that it was quite powerless in periodical fevers. In neither case was the natural tendency to cure of these affections sufficiently considered. In the absence of quinine, salicin may be employed in mild cases of *intermittent fever*. Salicin has been found efficient in preventing the development of acute *coryza* when given in doses of from 20 to 40 grains, and also in mitigating the symptoms of *hay fever*. It has been thought to moderate the pain of *lumbago*. In *neuralgia* of a periodical type, and not amenable to quinine, it is said to have been very efficient in doses of from 20 to 40 grains, given every hour for three or four hours. Even *diabetes* is alleged to have got well under the influence of this medicine!

Administration.—Salicin, although not very soluble, may be given in water in the dose of from 10 to 40 grains (Gm. 0.60–2.60). It is better to give the smaller dose and repeat it frequently than to administer a full dose at once. It may be administered in powdered liquorice extract.

SALIX, U. S.—SALIX.

Willow-bark, E.; *Écorce de saule*, Fr.; *Weidenrinde*, G.

The bark of *Salix alba*, Linné. Bentley and Trimen, *Med. Plants*, 234.
Nat. Ord.—Salicaceæ.

Origin.—The willows form a large genus, which is mostly confined to the northern temperate zone, and with some species extends into the Arctic regions. They are either trees or shrubs with flexible branches, and have alternate, short-petioled, and mostly more or less lanceolate, entire, or finely serrate leaves, with small or conspicuous stipules. The flowers are dioecious, in cylindrical catkins, each bract being one-flowered, and have at the base one or two glands, but no other floral envelopes. The fruit is a one-celled and two-valved capsule, and contains numerous minute seeds which are furnished with a silky down. Most of the species are exceedingly variable in some of their characters, and all grow in moist localities, along streams, etc. The species recognized by the Pharmacopœia is common in Europe, and is frequently cultivated, and has been to some extent naturalized, in North America. It grows to the height of 60 or 80 feet (18–24 M.), and belongs to the group of *crack willows*, which are characterized by having their branches brittle at the base. *Salix fragilis*, *Linne*, resembles this species. *Salix purpurea*, *Linne*, is mostly shrubby, with olive-green, brownish, or purplish bark, and has the branches not brittle at the base. A large number of hybrids have been observed between the different species. The bark is collected from the branches in spring, when it is easily removed from the wood.

Description.—Willow-bark is met with in fragments or quills. It varies in thickness between $\frac{1}{25}$ and $\frac{1}{12}$ inch (1–2 Mm.), is externally smooth or little wrinkled, varies in color between gray, brownish, and brown-yellow, is shining, when young has a somewhat metallic lustre, and is furnished with some roundish, small, suberous warts. The inner surface is smooth, pale-brownish, or cinnamon-colored. The bark may be readily torn in a longitudinal direction, but breaks transversely with some difficulty. Under the thin corky layer it has a green color, and the inner bast-layer is striate by very fine medullary rays, is arranged in tangential rows, and may be separated in thin shreds. The dry bark is nearly inodorous and has a bitter and astringent taste. Willow-bark collected from old wood is usually deprived of the more or less fissured corky layer, and consists of the pale-brownish liber, which breaks with a tough, splintery fracture and is less bitter than the branch-bark. The parenchyma of the primary bark contains scattered groups of crystals: the bast-layer is formed of tangentially-arranged bast-fibres, which are accompanied by crystal-cells and alternate with thin layers of parenchyma; the numerous narrow mostly one-rowed medullary rays impart to the bast a finely-checked appearance.

Constituents.—Salicin, the important medicinal constituent of willow-bark, has been described above. The other constituents are wax, fat, gum, and tannin. The crack willows appear to contain more tannin, and the purple willows more salicin. According to Johanson (1875), the tannin of willow-bark is a glucoside, and gives with ferric salts a blue-black precipitate, the liquid becoming purplish-red on the addition of soda. Johanson also showed the presence of a kind of sugar having a slightly sweet taste and reducing alkaline copper solution with difficulty, and of the glucoside *benzohelicin*, $C_{20}H_{20}O_8$, which was prepared by Piria (1851) by dissolving populin in cold nitric acid; it yields with sulphuric acid a yellow solution which, on the addition of water, becomes colorless and gives off the odor of salicylic acid.

The bark and leaves of different species of *Populus* contain, in addition to salicin, *populin* or *benzoyl-salicin*, $C_{20}H_{22}O_8$, which crystallizes in white needles of a sweet and somewhat acid taste, and yields, under the influence of dilute acids, benzoic acid and decomposition-products of salicin.

Physiological Action and Medical Uses.—Willow-bark was anciently employed in medicine as an astringent. Like simple bitters, it appears to increase the appetite and improve the digestion, but if its use is long continued it confines the bowels. It has been used in cases of *dyspepsia* and of general *debility* and to lessen excessive discharges from mucous membranes. It has had some repute as a *vermifuge*, and its powder has been applied as a dressing for unhealthy and gangrenous *ulcers*. Before being introduced into medicine willow-bark had been a popular domestic febrifuge. It was first recommended for the treatment of *intermittent fever* by Stone of London in 1763, and was reported to be efficient by many others down to the discovery of salicin in 1825.

Powdered willow-bark may be given in *doses* of from 20 to 60 grains (Gm. 1.30–4) three times a day as a tonic; as an anti-periodic at least an ounce (Gm. 32) must be

FIG. 245.

Willow-Bark: transverse section, magnified 15 diameters.

taken during an intermission. A decoction or infusion may be made with an ounce of the bruised bark to a pint (Gm. 32 to Gm. 500) of water.

SALVIA, U. S.—SALVIA.

Folia (Herba) salviae, P. G.; *Sage*, *Garden sage*, E.; *Sauge officinale*, Fr.; *Salbei*, G.

The leaves of *Salvia officinalis*, *Linné*. Bentley and Trimen, *Med. Plants*, 206.

Nat. Ord.—Labiatae, Monardeae.

Origin and Description.—Sage is a suffruticose perennial indigenous to Southern Europe and extensively cultivated in England, France, and Germany and in gardens in the United States. The stem is about 2 feet (60 Cm.) high, woody at the base, much branched, quadrangular, and whitish pubescent above. The leaves are opposite, petiolate, 2 or 3 inches (5–8 Cm.) long, thickish, ovate- or lance-oblong, obtuse or subacute, finely crenulate on the margin, wrinkled, grayish-green, and beneath soft hairy. The lower leaves are sometimes auriculate or rounded, more frequently narrowed, at the base, the upper ones smaller and nearly sessile. The flowers are in three-flowered cymes in the axils of the upper leaves or bracts, have a tubular, bell-shaped, bilabiate, brownish, pubescent calyx, with mucronate divisions, and a violet-blue, bilabiate corolla, with a short tube, a depressed, helmet-shaped upper lip, three-lobed, spreading lower lip, and two stamens. All parts of the plant are more or less glandular and have a peculiar, strong, aromatic odor, and a warm, bitterish, and somewhat astringent taste.

FIG. 246.

Salvia officinalis, *Linné*.

Constituents.—The most important constituent is volatile oil, of which the fresh herb yields $\frac{1}{4}$ to $\frac{1}{2}$ per cent., and, when recently dried, about three times this quantity. *Oil of sage* is of a greenish or yellowish color, has the density 0.86 to 0.93, commences to boil at 130° C. (266° F.), and is very

freely soluble in 80 per cent. alcohol. P. Muir (1876) found the portion boiling between 156° and 158° C. (312.8° and 316.4° F.) to be a terpene, $C_{10}H_{16}$, which yielded cymene under the influence of sulphuric acid and terephthalic acid when treated with sulphuric acid and acid chromate of potassium. The portion having the boiling-point 10° C. (18° F.) higher yielded identical products, and in the neighborhood of 200° C. (392° F.) an oxygenated portion was obtained, which Muir designated *salviol*, $C_{10}H_{18}O$, and at 260° C. (500° F.) a hydrocarbon of the formula $C_{18}H_{24}$. The stearepten of the oil melts at 187° C. (368.6° F.), and closely resembles ordinary camphor. The other constituents of sage are of no medicinal importance, and are those commonly found in plants; Hirsch did not succeed in obtaining tannin.

FIG. 247.

Sage-leaf: upper and lower surface.

Pharmaceutical Preparations.—AQUA SALVIÆ. Sage-water. Distil 10 parts of water from 1 part of sage-leaves.—P. G. 1872.

INFUSUM SALVIÆ. Sage $\frac{1}{2}$ troyounce, boiling water a pint.—U. S. 1870.

Off. Prep.—Vinum aromaticum, U. S.

Allied Species.—Most species of *Salvia* are aromatic and bitter. *Salvia pratensis*, *Linné*, and *S. sclarea*, *Linné*, are used in Southern Europe; *S. lyrata*, *Linné*, is common in North America, but only slightly aromatic.

SALVIA POLYSTACHYA, *Ortega* (*Salvia Chian*, *La Llave*). The fruit of this Mexican species is used under the name of *chia-seed*. It is about $\frac{1}{2}$ inch (2 Mm.) long, about $\frac{1}{10}$ inch (1.2 Mm.) broad, flattish-globular, gray marbled with brown, glossy, internally white and oily. The testa is covered with a transparent epithelium containing much insipid mucilage, which, according to Hiland Flowers (1882), is coagulated by ferric chloride; the white embryo contains a pale-yellow drying oil. According to Profs. Gray and Rothrock, the fruit of *Salvia Columbariæ*, *Benth.*, which is indigenous to New Mexico and westward, is likewise known as *chia-seed*. The fruit of *Salvia verticillata*, *S. verbenaca*, *S. Horminum*, *Linné*, and other species, is also mucilaginous.

POGOSTEMON PATCHOULY, *Pelletier* (*Pog. suave*, *Tenore*), is an East Indian hairy, suffruticose plant, with petiolate ovate or rhombic-ovate, doubly crenate-serrate leaves of a strong aromatic

odor. The volatile oil of *patchouly* is brownish-yellow, and begins to boil at about 257° C. (495° F.), but the greater part distils near 285° C. (545° F.). It contains a hydrocarbon (Gladstone) and a liquid oil, having the same composition as the stearopten present, $C_{15}H_{26}O$ (Montgolfier, 1877), which after purification melts at 55° C. (131° F.).

Medical Action and Uses.—Sage is an ancient medicine. From the time of Hippocrates, when it was reputed to be desiccant and astringent, it was used in chronic pulmonary complaints and uterine derangements and as a dressing for wounds and sores. Later on, it was regarded as emmenagogue, and used to arrest hæmoptysis and as a gargle for sore throat.

Sage is stimulant, tonic, and astringent. Pidoux states that, having caught cold during the month of July, an infusion of half an ounce of sage caused him to sweat copiously for several hours. Such effects are likely to be produced by a hot infusion of any stimulant herb. It is certain that a cold infusion of sage has in all ages been employed to moderate excessive sweats depending upon debility alone. A vinous infusion is to be preferred for this purpose. It is less serviceable in the colliquative sweats of phthisis accompanied by hectic fever, yet even in them it adds to the power of aromatic sulphuric acid when used as a vehicle for the latter. A strong infusion of sage has been employed successfully to hasten the drying up of the milk at weaning-time. Sage tea or an infusion of sage in red wine is a popular and efficient remedy for aphthous and other ulcers of the mouth and for all forms of sore throat; it is best used as a wash or gargle when sweetened with honey. Its power is increased by the addition of vinegar, alum, borax, or chlorate of potassium. Externally, similar applications are of great use in healing ulcers and the raw surfaces occurring in *intertrigo*, etc. The aromatic wine of the French Codex, and which is so largely used for such purposes, contains sage. Sage is much used as a seasoning for gross and fat meats, such as pork and goose. It is seldom prescribed internally, unless in an infusion, which is no longer official.

SAMBUCUS, U. S.—SAMBUCUS.

Sambuci flores, Br., P. G.; *Elder-flowers*, E.; *Fleurs de sureau*, Fr.; *Fliederblumen*, Hollunderblüthen, G.

The flowers of *Sambucus canadensis*, Linné (S. nigra, Linné, Br., P. G.). Bentley and Trimen, *Med. Plants*, 137, 138.

Nat. Ord.—Caprifoliaceæ.

Origin.—The American elder is suffruticose, attaining a height of 8 or 10 feet (2.4–3 M.) and grows in moist thickets and on the banks of streams throughout a great portion of North America. It has opposite mostly smooth leaves, with from seven to eleven short-stalked, oblong, pointed, serrate leaflets, the lower pair of which is frequently three-parted, and juicy, purplish-black, drupaceous fruits, containing three one-seeded hard nutlets and having an acidulous and sweetish taste. The bark, leaves, flowers, and fruit are sometimes medicinally employed, but only the flowers are recognized as official.

Description.—The flowers are in large, level-topped cymes, which terminate the small branches and are five-branched below and forked above. The marginal flowers are occasionally radiate; all have a superior calyx, with five minute teeth, a wheel-shaped, cream-colored, or whitish corolla, with a short tube and a spreading five-lobed limb, and five stamens which are inserted between the obtuse corolla-lobes. The flowers appear in June, and have in their fresh state a peculiar rather disagreeable odor, which becomes more pleasant and sweetish on drying. They are collected when in full bloom, and rapidly dried to prevent them from turning black; the corollas fall off very readily, and are separated from the stalks by shaking. Well-dried elder-flowers are of a pale brownish-yellow color, and have a slight peculiar odor and a sweetish, mucilaginous, and bitterish taste. The constituents of this drug appear to be closely allied to those of the European elder.

SAMBUCUS NIGRA, Linné, extends throughout the greater portion of Europe, Southern Siberia, and Northern Africa. It is a shrub or small tree, has the leaflets ovate-oblong and acute, and the flowers in smaller compound cymes than the preceding; otherwise the two species resemble each other very closely.

Constituents.—European elder-flowers contain as their most important principle a volatile oil which, according to the investigations of Eliason, Pagenstecher, and others, is yellowish and limpid, but mostly of a butyraceous consistence, of a strong odor and of a warm, bitterish, afterward cooling taste. The recently-dried flowers yield only $\frac{1}{3}$ to $\frac{1}{2}$ per cent. of it if the distilled water is extracted with ether. The remaining constituents of

the flowers are acrid resin, a little tannin, mucilage, albumen, and other common vegetable principles; among the salts are malates of potassium and calcium. Scheele found in the berries mucilage, sugar, and malic acid, and Kraemer (1846) obtained from the bark *viburnic acid*, which is identical with *valerianic acid*. C. G. Traub (1881) ascertained that the bark of American elder contains likewise valerianic acid, and in addition resin, tannin, sugar, etc. J. B. Metzger (1881) found in the berries sugar, gum, tannin, fat, etc.

Allied Species.—*SAMBUCUS EBULUS*, *Linneé*. All parts of this European species have a strong, disagreeable odor and a bitterish, somewhat acrid taste. At present the four-seeded fruit, which resembles elder-berries, but has a more agreeable taste, is occasionally employed. The plant is known as dwarf-elder, *E.*; yèble or hièble, *Fr.*; and Attich, *G.*

Pharmaceutical Preparations.—*SUCCUS SAMBUCI INSPISSATUS*.—Extract of elder-berries, *E.*; Rob de sureau, *Fr.*; Fliedermus, *G.*—Bruise fresh elder-berries, after 24 hours express the juice, allow to settle, decant, strain, and evaporate the clear liquid to the consistence of a soft extract.—*P. Cod.* It has a sweet acidulous taste and dissolves in water with a brown-red color.

Off. Prep.—*Aqua sambuci*, *Br.*

Medical Action and Uses.—Elder-berries (*S. nigra*) are cooling, aperient, and diuretic, and when their juice is fermented it forms a wine which is much used in England as a domestic cordial. The flowers are said to be poisonous to peacocks and the berries to hens (Strumpf). According to Cazin, cattle refuse to eat the leaves, caterpillars avoid them, and hence the shrubs are planted around the beds of kitchen-gardens; the flowers are used to preserve clothing from moths.

The ancients considered elder-bark and leaves as purgative and diuretic, and several centuries ago the leaves, bark, and seeds were much used in dropsy, and the flowers for fomentations, as they continue to be at the present time. From the flowers a water is distilled which is employed as a perfume, and an ointment is prepared with them for the treatment of *burns* and *excoriations*. An ointment made with the inner bark has been used in *tinea capitis*, as a dressing for *blisters* and various excoriations and sores, and in *erysipelas*, as well as for moderating the pain of *hemorrhoids*, and in poultices as an application to *gangrenous* tissues, glandular engorgements, etc. For most of these purposes an infusion of the flowers is employed. Porcher states (*Resources of the Southern Fields*, etc., p. 448) that "a decoction made by pouring boiling water over the leaves, flowers, or berries of the elder is recommended as a wash for wounds to prevent injury from flies. An ointment is used for the same purpose." In the same work elder is said to have been employed in an ointment—which, however, contained sulphur—in the treatment of *scabies*. Dr. T. A. Smith of Crève Cœur, Mo., informs us that a strong decoction of *sambucus* is employed in his neighborhood to expel *maggots* from parts not readily accessible, particularly the nostrils; and adds that a decoction made with the green leaves and shoots of the elder succeeded perfectly in driving away these creatures from the wounds made in cutting off lambs' tails when every other application had failed. It acted very promptly and was entirely unirritating. The young leaf-buds are said to be a drastic cathartic, but the fresh inner bark is more efficacious. The juice of the root of *S. nigra* has been found to act as a hydragogue cathartic in the dose of 1 or 2 ounces (Gm. 32–64), taken fasting. This dose excites copious salivation, followed by vomiting without excessive straining; later, watery stools occur, and continue for eight or ten hours. In this country similar effects have followed the use of the native elder-bark (*S. canadensis*) infused in hard cider. The expressed juice of the root of the official plant may be given in the *dose* of 2 fluidounces (Gm. 64) every 2 hours until its specific operation begins. A decoction is made by boiling an ounce of the inner bark in 2 pints of water until reduced to a pint (Gm. 32 in Gm. 1000 to Gm. 500); of this 4 fluidounces (Gm. 128) may be given at a dose.

SANGUINARIA, U. S.—SANGUINARIA.

Bloodroot, *Puccoon*, *Tetterwort*, *Indian paint*, *El.*; *Sanguinaire*, *Fr.*; *Blutwurz*, *G.*

The rhizome of *Sanguinaria canadensis*, *Linneé*. Bentley and Trimen, *Med. Plants*, 20. *Nat. Ord.*—*Papaveraceæ*.

Origin.—Bloodroot is a native of Canada and the United States, where it grows in open woods on a rich soil. In early spring the rhizome sends up one or two leaves and a slender scape about 4 or 6 inches (10–15 Cm.) high, bearing a single large white flower.

The leaves do not attain their full size until after the petals have been shed in April or May, and are then about 3 inches (75 Mm.) long and 4 or 5 inches (10–12 Cm.) wide, heart-shaped at the base, reniform in outline, palmately seven- or nine-veined, and divided into the same number of obtuse lobes; the upper surface is of a light green, the lower surface glaucous, whitish, and the veins often reddish. The calyx consists of two fugacious sepals, and the corolla of about eight oblong and obtuse petals; the stamens are in several rows, and the fruit, which ripens in June, is an oblong two-valved capsule tapering at each end and containing numerous roundish seeds with a strongly crested raphe. All parts of the plant contain a bright orange-red juice, but only the rhizome is employed.

Description.—The rhizome is 2 to 4 inches (5–10 Cm.) long and about $\frac{2}{3}$ inch (1 Cm.) thick, horizontal, slightly branched, cylindrical, and faintly annulate by leaf-scars. In the fresh state it is fleshy, and emits, when wounded, a dark-red juice; after drying it is reddish-brown externally, longitudinally wrinkled, and breaks with a short fracture of a slight waxy appearance. Transverse section shows a thin bark, which is in width about one-twelfth the diameter of the rhizome, a very fine cambium-line, and a white mealy inner portion, in which the circle of about eighteen small fibro-vascular bundles is not readily distinguished, and which contains a large number of small red resin-cells; the interior tissue is not unfrequently of a nearly uniform brownish-red color, due probably to the manner in which the drug was dried. The thin rootlets are mainly on the lower side, and in commercial bloodroot are mostly broken off, short remnants or sears only remaining; they have a bark about equal in thickness to the ligneous cord and contain scattered red resin-cells. Bloodroot yields a pale grayish-red, irritating powder, and has a slight heavy odor and a persistently bitter and acrid taste.

FIG. 248.

Bloodroot.

Constituents.—Dr. Dana (1828) obtained from bloodroot the alkaloid *sanguinarine*, which Probst considered identical with the alkaloid chelerythrine discovered by him (1838) in celandine (see page 423). The identity of the two was conclusively proven by Shiel (1855). Riegel (1845), and afterward Gibb (1860), isolated a second alkaloid, which they named *porphyrocine*, from its supposed identity with a constituent of opium formerly known by that name. It was obtained by exhausting the rhizome with dilute acetic acid, precipitating the sanguinarine with ammonia, neutralizing the filtrate with acetic acid, and precipitating with tannin; on decomposing the precipitate with either lime or potassa and exhausting with ether white, tasteless crystals are stated to be obtained, which yield with acids bitter and neutral salts. In 1856, E. S. Wayne announced the discovery of a third alkaloid, named *pucine* by Gibb. It was said to remain dissolved in ether after precipitating the ethereal solution of crude sanguinarine with sulphuric acid. L. C. Hopp (1875) proved it to be sanguinarine held in solution as sulphate by a trace of resin; he also found *sanguinarinic acid* of Newbold (1866) to be a mixture of impure citric and malic acids.

Sanguinarine, $C_{15}H_{17}NO_4$, is obtained from the syrupy alcoholic extract of *sanguinaria* by digesting it with dilute hydrochloric acid, filtering from the resin, precipitating by ammonia, dissolving the crude alkaloid in ether, and passing hydrochloric acid gas into the solution, when hydrochlorate of sanguinarine is precipitated. The pure alkaloid is in white verrucose or needle-shaped crystals, which are sternutatory, freely soluble in ether and alcohol, and yield with acids bright-red salts having a bitter and persistently acrid taste, like the alcoholic solution of the alkaloid. The second alkaloid observed by Riegel was obtained by F. W. Carpenter (1879) as a yellow mass which acquired with strong sulphuric acid a deep-purple color, intensified on the addition of potassium bichromate, the reaction resembling that produced by these two reagents with strychnine. F. L. Slocum crystallized the same alkaloid from ether in colorless, slightly bitter needles of an alkaline reaction, and in this pure state yielding with sulphuric acid a deep-purple color, which, however, was not permanent, and changed with chromate to yellow. It exists in minute quantity only, and is not precipitated by ammonia. Slocum examined also the red resinous matter which is separated by alcohol into two portions, both of which, when fused with potassa, yielded protocatechuic acid. C. W. Dodd (1882) found in 100 parts of air-dry bloodroot 10.9 moisture, 7.9 ash, 2.7 benzol extract, 19.9 alcohol extract, 16.2 water extract, 7.2 starch, and 1.11 sanguinarine.

Off. Prep.—Acetum sanguinariae, Extract. sanguinariae fluid., Tinet. sanguinariae, *U. S.*

Physiological Action.—In non-nauseating doses it increases the appetite and improves digestion. Rutherford and Vignal found that in dogs sanguinarine, when mixed with a small quantity of bile and water and placed in the duodenum, powerfully stimulated the liver, rendering, however, the bile more watery. In larger doses it nauseates and slows the pulse, and in excessive quantities sometimes excites vomiting, but more usually causes burning in the stomach, faintness, vertigo, impaired vision, general insensibility, coldness, extreme reduction of the force and frequency of the pulse, with irregularity and palpitation of the heart, great prostration of muscular strength, and sometimes a convulsive rigidity of the limbs. Fatal poisoning has resulted from an overdose of this medicine. The foregoing effects have been essentially reproduced in experiments upon animals by Dr. Robert Meade Smith (*Inaugural Thesis*, University of Pennsylvania, 1876), who concludes that sanguinarine, with which he experimented, affects and directly depresses the functions of the spinal cord, of the cardiac nerves, and of the heart itself. In man, sanguinarine, in doses of from $\frac{1}{2}$ to $\frac{1}{4}$ grain continued for several days, occasions nausea and sometimes vomiting, and a manifest reduction of the pulse-rate. 1 grain in solution, repeated at intervals of 10 minutes, may excite vomiting after the third dose.

Medical Uses.—The physiological action of sanguinaria bears no relation to its medicinal uses. In all cases in which the former is developed the depressing operation of the medicine is distressing and unsafe. Its only value is demonstrated, if at all, by its long-continued use in moderate doses, so as to produce its so-called deobstruent or alterative effects. These are supposed to be exhibited when it is used in the treatment of *atonic dyspepsia*, with "torpor of the liver," but in such cases the cure is probably due, in some degree, to the simultaneous regulation of the diet, etc. and abstinence from active medication. Possibly in protracted muscular rheumatism the medicine may deserve a trial. It has been used in *bronchitis*, *croup*, and *asthma*.

Powdered bloodroot has been employed as a *sternutatory* and as a stimulant to indolent and unhealthy *ulcers*. The latter effect probably led to its being used by quacks in the treatment of *cancer*. The fresh juice of the root is said to cure *warts*, and an infusion or decoction of the root has been applied to chronic *scaly* and *pustular eruptions*.

The *dose* of sanguinaria as an emetic is from 10 to 60 grains (Gm. 0.60–4). An infusion made with an ounce of the bruised root in half a pint (Gm. 32 in Gm. 250) of boiling water may be given in tablespoonful doses at short intervals. The official preparations represent the medicine fully.

SANGUIS.—BLOOD.

Sang, Fr.; *Blut*, G.

Description and Composition.—Blood is an animal fluid which passes to all organs through the circulation. In the inferior animals it is of a white color, while in the vertebrated animals it is red, and the red color is brighter in blood taken from the arteries than in that contained in the veins. Blood is not a simple solution of different compounds, but it is a kind of emulsion containing chiefly blood-corpuscles in suspension. According to Lehmann, 1000 parts of corpuscles contain 688 water, 16.75 hæmatin, 282.22 globulin, 2.31 fat, 2.60 extractive matter, and 8.12 mineral constituents, among which potassium salts predominate. The red color of blood-corpuscles is due to *hæmoglobin*, which under some conditions may be obtained in well-defined crystals, as was shown by B. Reichardt (1847); acids and alkalis decompose it into the red coloring matter hæmatin, which contains iron and may likewise be crystallized, and into the albuminoid compound globulin. 1000 parts of the liquid portion of blood contain 902.90 parts of water, 4.05 fibrin, 78.84 albumen, 1.72 fat, 3.92 extractive matter, and 8.55 mineral constituents, among which chloride of sodium predominates. The saline constituents both of the corpuscles and liquid are, besides iron, phosphates of calcium and magnesium, and chlorides, phosphates, and sulphates of potassium and sodium. The composition of blood varies, however, in different animals, and in the same animal if taken from different vessels. When left to itself, blood coagulates, forming a *clot*, *cruor*, which separates from the liquid portion, called *serum*. The clot consists of the fibrin, which has become insoluble, and of the corpuscles, while the serum is chiefly a solution of albumen and salts. According to Boussingault, the red color of the blood of the higher animals is not due to iron, since the white blood of mollusks contains about the same amount of iron, varying in different animals between about 0.04 and 0.06 part in 1000.

Bullock's blood has been used in the fresh state, and, according to W. C. Bakes (1872),

also evaporated to an extract (*extractum sanguinis*), and, if subsequently powdered, under the name of *pulvis sanguinis*.

Medical Action and Uses.—We shall not in this place discuss the nutritive qualities of blood, but only recall the fact that, in spite of the wise Mosaic law against eating blood, it is more or less used as food in several countries. We remember to have observed many years ago in the Roman market cakes of coagulated blood sold openly as food, and which disagreeably recalled the basins of human blood we had then but recently seen shed in hospital practice.

In 1873, Mr. Vacher, an English health officer, having learned that the serum of the blood of sheep and oxen was regarded by the journeymen in certain slaughter-houses as "a remedy of great value for the treatment of scrofulous children, and as little less than a specific in cases of seat- and tape-worms," undertook some experiments with it which confirmed him in his impression of its efficacy. When employed in the Birkenhead Borough Hospital it was found "most successful in cases of thread-worms, and less so in those of *Ascaris lumbricoides*; it failed almost entirely in *tænia*." It would seem unnecessary to introduce a new remedy for these entozoa when so many efficient anthelmintics are already available, especially when the proposed medicine is difficult to obtain in a fresh and sound condition and is of doubtful value. It has been proposed to render it more permanently available by drying it, but there is as yet no evidence of its virtues in that condition. There is, moreover, in our opinion, a serious objection to converting food into medicine, which is at present so much practised in the case of "charcoal biscuit," "beef biscuit," wines and elixirs of "beef and iron," etc. These preparations are far more apt to inspire an aversion to wholesome food than to quicken the appetite or improve the digestion. We submit that in the treatment of disease the laboratory and the kitchen should not be associated in the same prescription. The same objection does not exist against the administration of defibrinated blood by enema. It is claimed by Dr. Andrew H. Smith (*Amer. Jour. of Med. Sci.*, July, 1879, p. 242) that it is almost wholly absorbed; confines rather than irritates the bowels, as a rule; and that "in favorable cases" it quickens nutrition more than other remedies. Sansom (*Lancet*, Feb. 16, 1881) reports favorably of the method, stating that in urgent cases 2 or 3 ounces of the liquid should be injected into the rectum every two or three hours, and that in chronic cases, in which it supplements gastric alimentation, from 2 to 6 ounces should be administered twice a day. Moller has confirmed this experience by his own in several cases of extreme debility and anæmia. In one instance the weight of the patient and the proportion of red elements in the blood largely increased under this treatment (*Archives gén.*, Dec. 1882, p. 731). Before each enema is given the intestine should be washed out with tepid water slightly salted, and it is recommended that 10 or 15 grains of hydrate of chloral should be added to every enema. It may be mentioned that defibrinated blood has been injected into the peritoneal cavity, and also hypodermically, in cases of extreme exhaustion (Bareggi, *Medical Record*, xxiv. 239).

SANICULA.—SANICLE.

Sanicle, Fr.; *Sanikel*, G.

Nat. Ord.—Umbelliferæ, Orthospermæ.

Description.—The genus *Sanicula* is composed of perennial herbs with palmately divided and coarsely serrate radical leaves and irregular or compound umbels, having polygamous, rather capitate flowers, and few-leaved involucre and involucl. The fruit is nearly globular, and has the mericarps closely united, without prominent ribs, covered with hooked prickles, and containing five oil-tubes.

SAN. MARITANDICA, *Linné*, has the radical and stem-leaves five- or seven-parted and the divisions rather narrow; the staminate flowers are numerous and on slender pedicels, and the perfect flowers have elongated and recurved styles. The blackish root and the leaves are nearly inodorous, and have a somewhat bitter and persistent acrid taste. The American species are in some localities known as *black snakeroot* and *pool-root*.

Constituents.—C. J. Houck (1884) obtained from the air-dry root 8 per cent. of ash, volatile oil, resinous matter, tannin, and other common constituents. The ethereal extract is very aromatic and has a burning, acrid taste.

Allied Plants.—*SANICULA EUROPEA*, *Linné*, is a common European plant. The root is several-headed, branched, and dark-brown. The radical leaves are palmately five-parted, and the obovate wedge-shaped segments again three-lobed. The stem-leaves are few in number and small. The perfect flowers are sessile and the staminate flowers on very short stalks.

SAN. CANADENSIS, *Linne*, resembles the European species, but has three-parted stem-leaves, and is distinguished from the first species by the nearly sessile staminate flowers, the shorter styles, and the smaller number of fruits in each umbellet.

ASTRANTIA MAJOR, *Linne*, is a European plant, the root of which is known as *black sancicle*, and is occasionally used as *radix imperatoria nigra*. It consists of an oblique annulated rhizome about 4 inches (10 Cm.) long and $\frac{1}{4}$ inch (6 Mm.) thick, externally brown-black, internally whitish, and of fragile, shrivelled rootlets having a similar color; it resembles the roots of the preceding plants.

Medical Action and Uses.—Nothing appears to have been recently added to the often-repeated statements respecting the American species, that the aborigines of this country use sancicle in syphilis and diseases of the lungs, and that some physicians affirmed its virtues in chorea and intermittent fever. *S. europæa* has an acrid, astringent, and somewhat bitter taste, and is popularly employed in Germany and France as a remedy for profuse hæmorrhages from the lungs, bowels, uterus, or urinary organs, and for the cure of *diarrhæa*, *dysentery* and *leucorrhœa*, and externally as an application to *wounds*, *bruises*, etc. The fresh juice of the plant is prescribed in doses of $\frac{1}{2}$ ounce (Gm. 16) or more, and a vinous infusion of it is also given internally.

SANTALUM RUBRUM, U. S.—RED SAUNDERS.

Pterocarpî lignum, Br.; *Lignum santalinum rubrum*.—Red sandal-wood, E.; *Santal rouge*, Fr.; *Rothes Sandelholz*, G.

The wood of *Pterocarpus santalinus*, *Linne filius*. Bentley and Trimen, *Med. Plants*, 82.

Nat. Ord.—Leguminosæ, Papilionacæ.

Origin.—This species is a small or medium-sized tree, with a trunk of a foot (30 Cm.) or more in diameter. The leaves are pinnately trifoliate, with orbicular ovate emarginate leaflets. The flowers are small, yellow, and in lax racemes. The pod is roundish, sickle-shaped, winged, and contains one or two seeds. It grows wild only in the Madras Presidency, but is cultivated in Southern India.

Description.—Red sandal-wood is met with in commerce in hard and heavy billets, which are deprived of the light-colored sap-wood, are externally of a dark-brown or reddish-brown color, and split irregularly and coarsely splintery in a longitudinal direction. If cut transversely, it is of a somewhat variegated appearance, the circles being alternately rather broad and dark brown-red and narrow and lighter colored. The medullary rays appear as delicate red radiating lines. In the shops the wood is usually found in chips or in a coarse and irregular powder of a brown-red color, nearly inodorous and having a scarcely perceptible astringent taste. A red resinous mass exudes from the wood on heating it. Red saunders is distinguished from other red-colored woods by the characters given, and by means of water, which is not colored by it; it imparts a deep-red color to alcohol, and this tincture acquires a dark-violet color on the addition of ferric chloride.

Constituents.—The coloring principle of red saunders is *santalic acid* or *santalin*, $C_{15}H_{14}O_5$, which may be obtained, according to Leo Meier (1849), by precipitating the tincture with acetate of lead, washing the precipitate with hot alcohol, and decomposing it with sulphuretted hydrogen in the presence of alcohol. Santalic acid forms microscopic needles of a beautiful red color, is inodorous and tasteless, melts at $104^{\circ} C.$ ($219.2^{\circ} F.$), is insoluble in water, but dissolves in concentrated sulphuric acid with a deep-red, in alkalies with a violet, in alcohol with a blood-red, and in ether with a yellow, color; it is soluble in the volatile oils of cinnamon, cloves, bergamot, and bitter almond, but is insoluble in most other volatile and fixed oils. The coloring matter, as obtained by Franchimont (1879), was amorphous, had the composition $C_{17}H_{16}O_6$, and yielded resorein and acetic acid when fused with potassa. L. Meier (1849) obtained several other compounds, which appear to be decomposition-products. Weidel (1870) obtained 0.5 per cent. of colorless and inodorous sealy crystals of *santal*, $C_8H_6O_3$, which resemble benzoic acid in appearance, but are tasteless; they are insoluble in water, carbon disulphide, chloroform, and benzol, sparingly soluble in alcohol, ether, ammonia, and alkali carbonates, but freely soluble in potassa and soda, these solutions turning yellow, red, and green. The alcoholic solution becomes red with ferric chloride. Cazeneuve's *pterocarpin*, $C_{17}H_{16}O_5$ (1875), is likewise colorless and crystalline, but is soluble in ether, chloroform, and carbon disulphide. Red saunders is free from gallic acid, but appears to contain a minute quantity of tannic acid, which has not been further examined.

Off. Prep.—*Tinctura lavandulæ comp.*, U. S., Br.

Medical Uses.—Red sandal-wood has no medicinal virtues, and is used only as a coloring agent.

SANTONICA, U. S., Br.—SANTONICA.

Flores cinæ, P. G.; *Semen cinæ*, s. *contra*, s. *sanctum*, s. *santonici*.—*Levant wormseed*, E.; *Semen-contra*, *Barbotine*, *Semencine*, Fr.; *Wurmsamen*, *Zittwersamen*, G.

The unexpanded flowers of *Artemisia maritima*, Linné, var. *Stechmanniana*, Besser. Bentley and Trimen, *Med. Plants*, 157.

Nat. Ord.—Compositæ, Senecionidææ.

Origin.—Levant wormseed is obtained from Asia, and appears to be mainly if not exclusively collected in the northern part of Turkestan, and to be sent to the great fair at Nishnei-Novgorod, and thence to St. Petersburg and Western Europe. Berg characterized the plant botanically from the commercial drug as *Artemisia Cina*, Berg, and Willkomm (1872) described under the same name a plant brought from Turkestan; but the flower-heads of this plant do not entirely resemble the wormseed of trade, in that they have fewer scales (*Pharmacographia*). Flückiger and Hanbury consider the drug to be obtained from the plant mentioned above, which is identical with *A. Lercheana*, Karel et Kiri!, *A. maritima*, var. *pauciflora*, Ledebour, and *A. pauciflora*, Weber. The typical form of *A. maritima*, Linné, grows in salt marshes in Western Europe, extends under various forms eastward to Western Asia, and has tomentose flower-heads with about eighteen scales.

Description.—Levant wormseed consists of unexpanded flower-heads, which are about $\frac{1}{12}$ to $\frac{1}{8}$ inch (2–3 Mm.) long and $\frac{1}{25}$ inch (1 Mm.) wide, oblong-ovoid in shape, obtuse at both ends, smooth, somewhat shining, and of a grayish-green color, changing to brownish-green on exposure to light. The involucre is densely imbricate, and consists of twelve to eighteen keeled scales, of which the lower ones are smallest and ovate in shape, and the oblong upper ones have a scarious margin and are dotted with numerous minute yellowish glands. The florets are four or five in number, but undeveloped and minute. The drug has a strong peculiar odor and a bitter camphoraceous and disagreeable taste, and frequently contains fragments of the thin peduncles and of linear leaves.

Constituents.—Levant wormseed has been frequently examined, and found to contain as active principles about $1\frac{1}{2}$ or 2 per cent. of a crystalline body, *santonin* (see below), and 1 or 2 per cent. of volatile oil; also resin and various other less important constituents. *Oil of Levant wormseed* is pale-yellow, limpid, has the density 0.92, commences to boil at about 170° C. (338° F.), is readily soluble in ether and alcohol, and, according to Völkel, is a mixture of various oxygenated compounds, of which Hirzel (1854) distinguished *cinæbene*, *cinæbene camphor*, and others.

Pharmaceutical Uses.—Levant wormseed is the source of santonin.

EXTRACTUM CINÆ. Exhaust the powdered drug with ether or with a mixture of equal parts of ether and alcohol (*P. G.* 1872) and evaporate the tincture until the ether has been completely dissipated, *P. Cod.* (or to the consistence of a soft extract, *P. G.*). The yield is about 20 or 25 per cent. The extract is of a green or green-brown color, and on keeping becomes granular, depositing crystals of santonin. It should be well agitated before dispensing it.

Allied Drugs.—The unexpanded flower-heads of a species of *Artemisia*, supposed by some to be derived from *A. ramosa*, Smith, have sometimes entered commerce from North-western Africa, and are known as *Barbary wormseed*. This consists of roundish-ovate flower-heads having a grayish-brown color, covered with a whitish down, and mixed with numerous fragments of peduncles and of leaves; the outer scales are roundish and the inner ones ovate. Another variety has occasionally been observed in Europe and described as *Indian wormseed*. It is only about one-half the size of the official drug, and is hairy and of a more yellowish color. We have repeatedly observed American wormseed to be sold in place of santonica, to which it bears no resemblance (see page 424).

Action and Medical Uses.—This medicine was introduced into Europe by the Crusaders, and has ever since been employed as an anthelmintic. After the discovery and isolation of santonin, the proximate principle upon which the “seeds” depend for their virtues, it became less used than formerly. The seeds were then held to be stomachic in

small doses, general stimulants of the circulatory and nervous systems in larger doses, and in still larger quantities were found to produce gastric oppression, nausea, vomiting, and diarrhœa. Sometimes they gave rise to symptoms of cerebral congestion.

Santonica is used almost exclusively as a vermicide for lumbricoid worms and *ascarides* of the rectum, but occasionally for *tapeworm* also. For the last it is of little efficacy; for the other parasites it is one of the best remedies. It is administered in coarse powder with honey, molasses, or some analogous liquid, to which jalap may be added for its purgative effect. The *dose* is from 10 to 60 grains (0.60–4) three times a day.

SANTONINUM, U. S., Br., P. G.—SANTONIN.

Santonine, Fr.; *Santonin*, G.

Formula $C_{15}H_{18}O_8$. Molecular weight 246.

Preparation.—Santonin was discovered in 1830 simultaneously by Kahler and by Alms, and since that time has been frequently examined by chemists. The process given by the British Pharmacopœia has been elaborated by the researches of Calloud, Cerutti, Mialhe, and others. The santonin is extracted by boiling 16 parts of bruised santonica with 5 parts of lime and sufficient water, and, after straining, repeating the operation with 2 parts of lime. In the process of Trommsdorff (1834) diluted alcohol is used in the place of water, and digesting instead of boiling. The lime and santonin form a compound soluble in water and alcohol, and on concentrating the liquors an aqueous solution of calcium santonin remains, contaminated with coloring and extractive matter and with resin held in solution by lime. The calcium compounds are decomposed by either acetic or hydrochloric acid, which form freely-soluble calcium salts and liberate the santonin, together with resin and other compounds. The impure santonin thus obtained may be freed from some of its impurities by washing it with dilute ammonia, or, without being thus treated, may be purified by recrystallization from hot alcohol, a little charcoal being used to remove coloring matter; the resin will remain dissolved in the alcohol. The yield is $1\frac{1}{2}$ to nearly 2 per cent. In 1876, 427 pounds of santonin were imported into the United States, 63 pounds in the following year, and 1508 pounds in 1883.

Properties.—Santonin crystallizes in flat, rhombic prisms, which are colorless, of a pearly lustre, and of a slightly bitter taste, which is gradually developed, but the solutions of santonin are persistently bitter. When heated to about 170° C. (338° F.) it melts to a colorless liquid, which, on being slowly cooled, becomes again crystalline, but when rapidly cooled usually remains amorphous and gum-like until after it has been moistened with alcohol, ether, or acetic acid, or has been heated again to a little over 40° C. (104° F.). When carefully heated in small quantities to a little above its melting-point, it sublimes without decomposition in white needles; but if larger quantities of it are heated, dense yellowish, irritating vapors are formed, condensing to a resinous mass; decomposition takes place, and at a higher heat santonin burns in the air with a sooty flame and without leaving any fixed residue. Santonin dissolves in about 5000 parts of, and is therefore nearly insoluble in, cold water, and requires 250 parts of boiling water and 40 parts, U. S. (44 parts, P. G.), of cold alcohol for solution. Trommsdorff found santonin to be dissolved at 17.5° C. (63.5° F.) in 43 parts, and at 80° C. (176° F.) in 2.7 parts, of alcohol spec. grav. .848, while at the same temperatures 280 and 10 parts of an alcohol having the density .928 were necessary. Santonin dissolves in 72 parts (160 parts, U. S.) of cold and 42 parts of boiling ether (Trommsdorff), and in 4.35 parts (4 parts, U. S., P. G.) of chloroform (Schlimpert); these solutions have a neutral reaction. It is likewise soluble in strong acetic acid, in volatile oils, and in warm olive oil. Santonin should be kept excluded from the light or in amber-colored bottles. Air has no effect upon it, but in the sunlight it acquires a yellow color, and, according to Sestini (1864, 1865), is converted into *photo-santoninic acid*, $C_{23}H_{34}O_8$, which is more freely soluble in simple solvents, has a bitter taste, when pure is colorless and inodorous, and melts near 65° C. (149° F.). The coloring matter produced at the same time is of a resinous nature. Santonin yields with sulphuric acid a colorless solution, and is precipitated without alteration by water; but the color of the solution changes to yellow, red, and dark-brown, and then gives with water red or brown resinous precipitates (Trommsdorff). Santonin is transiently colored red by hot alkalies and alkaline earths. "With alcoholic solution of potassa it yields a scarlet-red liquid, which gradually becomes colorless."—U. S. "On boiling 5 parts of santonin and 4 parts of sodium carbonate with 60 parts of alcohol and 20 parts of water the liquid has alternately a red and yellow color."—

P. G. After the solutions in alkalies or alkaline earths have become colorless, they yield insoluble precipitates with the salts of most heavy metals. According to Hesse (1874), these compounds are true salts, and on liberating from them the *santonie acid* it may be obtained from the hot aqueous solution in white rhombic crystals, which do not turn yellow in the light, are sparingly soluble in cold water, but are readily soluble in alcohol, ether, chloroform, and glacial acetic acid, and have the composition $C_{15}H_{20}O_4$. The official santonin is therefore *santonie anhydride*.

Impurities.—Santonin has been sometimes adulterated with *boric acid*, which imparts to the flame of alcohol a green color, and on being heated upon platinum-foil is left behind as a glass-like mass, the solution of which turns turmeric-paper brown. *Strychnine* has been mistaken for santonin; it is readily detected by the bluish-purple color produced by sulphuric acid and a little potassium bichromate. *Picric acid*, which has been mistaken for santonin colored yellow by light, is very bitter, and may be recognized by the behavior described on page 86.

Tests.—"If the colorless solution of santonin in sulphuric acid be precipitated by water, the supernatant liquor should not be altered upon the addition of test solution of bichromate of potassium or of iodide of mercury and potassium (absence of alkaloids)."—*U. S.* "After boiling for some time 1 part of santonin with 100 parts of water and 5 parts of diluted sulphuric acid, the filtered liquid should not have a bitter taste, and on the addition of a few drops of solution of potassium chromate should not give a precipitate (of yellow crystalline strychnine chromate)."—*P. G.*

Pharmaceutical Preparation.—*TROCHISCI SANTONINI, Br., P. G.* The santonin lozenges (*U. S.* 1870) weighed about 20 grains and contained $\frac{1}{2}$ grain of santonin and 18 grains of sugar; those of the French Codex are colored by carmine, and contain 0.01 Gm. ($\frac{1}{8}$ grain); while those of the *P. G.* (which does not give a formula) are to contain 0.025 Gm. ($\frac{2}{9}$ grain), and those of the *Br. P.* 1 grain (total weight 17 grains).

Physiological Action.—*On Animals:* Given to rabbits in 30-grain doses, the animals appear to be much depressed, they pass purplish or yellow urine freely, and gradually die of exhaustion. In larger doses it occasions trembling of the limbs, insensibility, rigidity, and opisthotonos, alternating with convulsions, salivation, and dilatation of the pupils. It is thought by some experimenters that death by santonin is due to spasm of the respiratory muscles. Manometric observations appear to show that it is not caused by failure of the heart. After death the heart, lungs, brain, and spinal marrow are found engorged with blood.

On Man: The most remarkable effect of medicinal doses of this substance is that the whole field of vision appears yellow or yellowish-green; if the dose is large, it may be purplish or even red. The effect seems to be due to changed conditions of the retina or of the brain, and not, as was formerly supposed, to a staining of the humors of the eye. When given in large doses, as 5 grains or more, santonin imparts to the urine a deep-saffron color and stains the linen as bilious urine does. (For the distinction between urine colored by santonin and that stained by rhubarb see Munk, *Virchow's Archiv*, lxxii. 136.) At the same time it operates strongly as a diuretic. When the urine grows alkaline by putrefaction, or is made so by the addition of an alkali, the saffron tint is replaced by a violet or purplish color. In doses of 3 grains santonin may occasion nausea and vomiting, with abdominal pain, thirst, giddiness, and diarrhoea. (Compare Labbé, *Practitioner*, xxii. 284.) Decidedly poisonous effects sometimes arise from doses which are quite insignificant in comparison with those which some experimenters have taken without serious inconvenience. For example, a child six months old was rendered amaurotic for two months by a dose of 5 grains of santonin. In another case 2 grains, given to a child two years old, occasioned convulsions, injection and heat of the face and head, twitching of the eyeballs, dilatation of the pupils, foaming of the mouth, clenching of the teeth, stertorous breathing, and jerking of the arms. On the morrow recovery was complete. In a third case a healthy child of two years swallowed two santonin troches at 6 o'clock in the morning. No result appeared until 4 in the afternoon, when suddenly the muscles of the left side of the face began to twitch and the pupils to dilate. Then clonic convulsions affected the left side, beginning at the fingers, and these were followed by muscular rigidity of the same side. After a quarter of an hour the spasms subsided, but in the course of an hour were renewed, the voice meanwhile becoming quite extinct. The spasms were at intervals repeated for several days, during which the respiratory act grew very feeble, and artificial respiration was resorted to (Becker). A child of five years took 5 grains of santonin. She immediately complained of pain in the stomach; in a minute or two convulsions came on, with insensibility. There was neither vomiting

nor purging. Death took place in 35 minutes. Post-mortem, the stomach was inflamed in patches, and the duodenum throughout. The right heart was contracted and contained no blood; the left contained about 1 ounce of black fluid blood (Kilmer, *St. Thomas's Hospital Reports*, N. S., x. 247, where the tests for santonin are discussed). In other cases it is not the nervous but the digestive apparatus that is chiefly affected, and violent vomiting and purging, followed by collapse, produce an attack like one of cholera morbus. In all cases the urine has the characteristic color. Although recovery generally takes place after such grave symptoms, they occasionally terminate in death. These illustrations suffice to prove the necessity of caution in the administration of santonin.

Medical Uses.—The chief practical value of santonin consists in its power of destroying *lumbricoid worms*, and in a less degree rectal *ascarides*. A single dose of about 2 grains has sufficed to cause the expulsion of one hundred and sixty-six of the former species. It should be prescribed in doses not larger at first than 1 grain (Gm. 0.06) for adults and $\frac{1}{2}$ grain (Gm. 0.016) for children, and ought to be taken at night, both because its action upon the parasites is less interfered with by food at that time, and because the yellow vision which it may occasion will not then be a source of so much annoyance. Early on the following day a dose of castor oil or of some other purgative should be given. As santonin in substance is almost devoid of taste and smell, it may be prescribed with powdered sugar or in jelly. Pastilles or troches of santonin, made with chocolate, are much used and are very efficient. Lewin recommends that it be administered in oil, which prevents its absorption by the patient, but increases its action upon the worms (*Practitioner*, xxxi. 65). (For the mode of action of santonin as a vermifuge see Guermonprez, *Bull. de théráp.*, cii. 89.) Santonin has also been employed with alleged advantage in the treatment of *whooping cough*, as a diuretic in cases of *renal colic*, and for subacute and chronic inflammation of the *choroid* and *retina*, especially of an atrophic character. But in none of these affections has its utility been demonstrated. Internal and external stimulants, heat, cold, and artificial respiration, have all been employed in *poisoning by santonin*, but of these the last is the only one of positive value. Evacuants should be used to remove any of the drug remaining in the alimentary canal, and inhalations of ether to control the spasms.

SAORIA.—SAORIA.

The fruit of *Mæsa lanceolata*, *Forskål*, s. *M. picta*, *Hochstetter*.

Nat. Ord.—Myrsinacæ.

Origin and Description.—Saoria is a shrub growing throughout Abyssinia at the height of about 7000 feet (2150 M.). The fruit, which is the part employed, is drupaceous, globular-ovate, united with and about two-thirds of its length covered by the calyx, about $\frac{1}{4}$ or $\frac{1}{2}$ of an inch (3–4 Mm.) in diameter, often crowned by the short style and capitate stigma, yellowish- or brownish-green, and containing numerous small turbinate, angular seeds, which are flattened above and imbedded in a resinous mass adhering to the central placenta. Saoria has a bitterish, pungent, and acrid taste.

Constituents.—According to the analysis of Apoiger (1857), saoria contains a little volatile oil, various organic acids, tannin, reacting green with iron salts, an acrid principle, fixed oil, pectin, and other common vegetable principles. The ash of the dried fruit amounted to 7.76 per cent., and contained 0.30 per cent. of boric acid.

Allied Drug.—MYRSINE AFRICANA, *Schimper*, belonging to the same natural order, grows throughout the greater portion of Africa. The fruit, *tatzé* or *satzé*, has been used like the preceding, from which it differs in being more globular, not united with the calyx, of a reddish-brown color, and in containing only one nearly globular seed, which is grooved at the base. The taste of the fruit is more disagreeable than that of saoria.

Medical Action and Uses.—Saoria gives a violet tint to the urine and occasions slight nausea and liquid stools. According to some authorities, it is a more certain remedy for *tania* than the indigenous tæniifuges of France, but others regard its action as uncertain. It may be given in powder, mixed with porridge, in the dose of 1 ounce or $1\frac{1}{2}$ ounces (Gm. 32–48).

TATZÉ has a persistently acrid and disagreeable taste, and is apt to produce vomiting and purging. Dr. Strohl found it partially successful in six cases of *tania*. He administered from 4 to 6 drachms (Gm. 128–192) of the powder in a liquid vehicle.

SAPO, U. S., Br., P. G.—SOAP.

Savon, Fr.; Seife, G.

Preparation.—Soaps may be obtained by combining fatty acids (see page 1032) with alkalis, but they are generally prepared by boiling fats with a solution of caustic soda or potassa, when the fatty acids unite with the alkali, the soap remaining dissolved in the water, together with the glycerin which is liberated from the fat. The lye used in this operation is employed in a rather diluted state, is gradually added, and an excess of it is mostly used, since the saponification is thereby much facilitated, and the free alkali may be readily removed from the soap. The decomposition of the fats being effected by the gradual conversion of tripalmitin, etc. into di- and mono-palmitin before saponification is completed, the boiling must be continued until the mixture becomes transparent and rather tenacious. The soap is separated from the lye by adding common salt to the liquid, soap being insoluble in the solutions of most salts of potassium and sodium. If potassa has been used for saponification, the sodium chloride serves also the purpose of converting the potassa soap into soda soap. When the soap has separated from the liquor and sufficiently solidified it is transferred into wooden frames until it is stiff enough to be cut into bars, which are exposed to the air in a warm place until they become hard and dry.

Properties and Composition.—Soaps are salts of the fat acids, and if soluble have an alkaline reaction and taste. Commonly, the term "soap" is restricted to such of these salts as contain potassa or soda as the base and are soluble in water. The compounds with earthy and metallic bases are chemically analogous to these *soluble soaps*, but, being insoluble in water, are often distinguished as *insoluble soaps*. Of this latter kind two are recognized by the pharmacopœias—namely, lead plaster (p. 570) and liniment of lime (p. 883). Other insoluble soaps are extensively employed for rendering fabrics *waterproof*, and are produced by impregnating such fabric first with aluminium acetate or soluble salt of calcium or barium, and afterward steeping it in a solution of soap. The consistence of soap depends in part on the nature of the fat and in part on the alkali. Drying oils yield softer soaps than non-drying oils, and of the latter those containing much olein furnish soaps which are less hard, but more freely soluble in water and alcohol, than those rich in palmitic or stearic acid. Soda soaps are invariably harder than potassa soaps, which are mostly deliquescent, and therefore remain soft; dry potassium palmitate readily absorbs from the air about 50 per cent., and the oleate about 160 per cent. of moisture, while the corresponding sodium compounds absorb only 8 and 12 per cent. Soaps have mostly a white color when pure; the color and the marbled appearance of many soaps are due either to accidental impurities or to coloring matter contained in the oil, or they are produced by the intentional addition of coloring matters or of metallic salts, like sulphate of iron, in which case the result is due to the presence of an iron soap. Good soluble soaps have a slight fatty but not a rancid odor, or they have the fragrance of the fat (palm oil, etc.) from which they have been made.

The well-known detergent properties of soap depend upon its decomposition by a large quantity of water into acid and basic salts, of which the latter contain about 50 per cent. more alkali than the former, and act as solvents of fats and other matters; in this respect their action is similar to, but milder than, that of caustic alkali. So-called *hard water* is unsuited for washing on account of calcium or magnesium salts which are contained in solution, and which form insoluble soaps by double decomposition.

Examination and Valuation.—Soaps frequently contain a large amount of water—in some kinds 40 or even 50 per cent. From 12 to 15 per cent. of water is usually regarded as admissible for good air-dry Castile soap. The water is determined from a weighed quantity of the soap reduced to thin shavings, which are exsiccated at a temperature between 100° and 110° C. (212° and 230° F.). On treating the powdered soap with benzin or benzol or with ether, any unsaponified fat present will be dissolved, and on the evaporation of the solvent may be weighed; rosin oils and tar oils sometimes incorporated with soap are extracted by the same solvents. By incinerating another portion of the soap the soda may be determined from the residue, and should be about 10 or 11 per cent. for the exsiccated soap; if this quantity is exceeded, free alkali is most likely present. The dry soap is then dissolved in strong alcohol, in which sodium and potassium carbonate are insoluble, and, after separation from the alcoholic solution, may be estimated by titration with normal oxalic acid. On passing carbonic acid gas into the alcoholic liquid the caustic alkali will be precipitated as carbonate, and may be estimated as before. The solution may now be mixed with water, and again titrated with

an acid for estimating the combined alkali. By decomposing a solution of soap with hydrochloric acid, washing, and collecting the fat acid, its weight may be ascertained, and should be near 90 per cent. of the dried soap. The melting- and congealing-points of these mixtures will usually give some indication of the nature of the fat used for preparing the soap. The acid liquid may be employed for the determination of glycerin if present; it is concentrated by evaporation and dried, care being taken to prevent charring; on exhausting the saline residue with absolute alcohol the glycerin will be dissolved, and on evaporating this solution at about 60° C. (140° F.) it will be left behind. Adulterations with starch, chalk, clay, and similar compounds are ascertained by their insolubility in hot water or alcohol. Common soaps are sometimes mixed with resin soap (an alkaline solution of rosin being incorporated) or with alkali silicate. There is usually no difficulty in recognizing the presence of rosin, but we know of no method for accurately determining its amount. F. S. Gladding (1882) recommends decomposing the solution of soap in alcoholic ether by powdered silver nitrate; the silver resin compound remains in solution, is decomposed by hydrochloric acid, the solution evaporated, and the resin weighed. Sodium silicate is insoluble in alcohol, and the amount of silica present may be determined in the usual way by dissolving this residue in water, acidulating with hydrochloric acid, evaporating to dryness, and dissolving the salts in acidulated water. Free alkali cannot be recognized by litmus-paper, since soap solutions possess an alkaline reaction; but if powdered soap is mixed with calomel, and the mixture is moistened with distilled water, it will acquire a gray or blackish color in proportion to the amount of free alkali present; its solution in distilled water gives with corrosive sublimate a white precipitate, which is yellowish or brown-red in the presence of alkali or alkali carbonate.

Medicinal Soaps.—SAPO. *U. S.*; Sapo durus, *Br.*; Sapo oleaceus, s. hispanicus, s. venetus.—Soap, Hard soap, Castile soap, *E.*; Savon blanc de Marseille, Savon d'Espagne, *Fr.*; Oelseife, Spanische Seife, *G.*—It is prepared from olive oil and soda, and should be white or grayish-white, free from rancid odor, hard, and should not become moist on exposure; it should be completely soluble in alcohol and in water, should not impart an oily stain to paper, and on incineration should yield an ash which is not deliquescent. *Mottled Castile soap* is a similar soap, which is more or less colored by the addition of an iron salt; internally it is white, mottled with black, changing to red-brown on exposure. The *U. S. Pharmacopœia* requires fresh soap to contain not over 34 per cent of water, but omits to state the limit of water allowable in soap used for preparing soap liniment; it gives no test to prove the absence of caustic alkali, and permits the presence of 3 per cent. (equal to 4.55 per cent. for dried soap) of matter insoluble in alcohol, of which at least 2 per cent. (3 per cent. for dried soap) should be soluble in water. "The aqueous (and alcoholic, *P. G.*) solution of soap should remain unaffected on the addition of solution of hydrosulphuric acid."—*U. S.* Some of the compounds of metals with fat acids are somewhat soluble in alcohol, but they are insoluble in water; the test given, therefore, has reference to the mixture or turbid solution in water, which should not be colored brown or black by sulphuretted hydrogen. Stearate and palmitate of sodium being sparingly soluble in cold alcohol, an adulteration of olive-oil soap with such prepared from animal fat is detected by the latter separating in the form of a jelly on the cooling of the alcoholic liquid. "A 4 per cent. alcoholic solution should not gelatinize on cooling (absence of animal fats)."—*U. S.*

SAPO MEDICATUS, *F. Cod.*, is a soda soap prepared from expressed almond oil, and agrees in its principal characters with the preceding. The soap recognized under the same name by the *P. G.* is a soda soap made with equal weights of olive oil and lard; it is required to be free from alkali, and may be used in the preparation of opodeldœ (see page 886).

SAPO ANIMALIS, *Br.*; Sapo domesticus.—Curd soap, *E.*; Savon animal, *Fr.*; Hausseife, *G.*—It is made with soda and a purified animal fat consisting principally of stearin. It resembles the preceding; its solution in boiling alcohol, after cooling, forms a translucent jelly-like mass, which constitutes the basis of opodeldœ.

SAPO VIRIDIS, *U. S.*; Sapo mollis, *Br.*; Sapo kalinus, *P. G.*—Green soap, Soft soap, *E.*; Savon vert, *Fr.*; Kaliseife, Grüne Seife, *G.*—Heat solution of potassa (spec. gr. 1.144) 135 parts: add gradually linseed oil 100 parts; continue the heat for 30 minutes, then add alcohol 25 parts, and as soon as the mixture has become uniform add gradually water 200 parts, and heat until the mass becomes translucent and will be soluble in hot water without separating any oil; evaporate to 150 parts.—*P. G.* According to Hirsch, the saponification is rapidly completed after the addition of the alcohol, rendering the further addition of water unnecessary.

Soft soap is directed to be made from olive oil (*Br.*) or other fixed oils (*U. S.*). Commercial soft soap (*Sapo kalinus venalis, P. G.*) is frequently made of fish oil, rancid fats, etc., has generally a nauseous odor, and varies in color from yellow or green to black, pigments being sometimes incorporated. Prepared by the above formula, it is a brownish-yellow, transparent, soft, unctuous mass, of a slight but not repulsive odor, free from granular admixtures, and completely soluble in water and alcohol. It is stated to be greenish-yellow (*U. S.*) or yellowish-green (*Br.*), to yield nothing to warm benzol (*U. S.*), and to not impart an oily stain to paper (*Br.*); it has an alkaline reaction, and when incinerated leaves a very deliquescent ash of potassium carbonate. It should contain not over 40 per cent. of moisture (*U. S.*), but, being very hygroscopic, generally contains more. The granules frequently seen in the commercial article are sodium stearate, which separates from the jelly-like mass; sometimes starch, earthy carbonates, or similar compounds are added to produce this appearance. The adoption by the U. S. P. of the antiquated term *Sapo viridis* is unfortunate, since soft soap, even if made from green hempseed oil, will become brown-yellow unless artificially colored.

Off. Prep.—1. *Of hard soap*: Empl. cerati saponis, Empl. resinæ, *Br.*; Empl. saponis, Extr. colocynthidis comp., *U. S., Br.*; Linim. potassii iodidi cum sapone, *Br.*; Linim. saponis, Pil. aloes, Pil. aloes et asafœtidæ, *U. S., Br.*; Pil. asafœtidæ, *U. S.*; Pil. cambogiae comp., *Br.*; Pil. opii, Pil. rhei, *U. S.*; Pil. rhei comp., Pil. saponis comp., Pil. scillæ comp., *Br.*

2. *Of curd soap*: Pil. scammonii comp., Suppos. acidi carbolici cum sapone, Suppos. acidi tannici c. sapone, Suppos. morphinæ c. sapone; it may also be substituted for the hard soap in preparing Linim. potass. iodidi c. sapone, *Br.*

3. *Of soft soap*: Linimentum terebinthinæ, *Br.*

History.—Pliny, after speaking of several ammoniacal preparations as resolvents of scrofulous tumors, says: "Soap, invented by the Gauls to make the hair yellow, may also be employed. It is prepared with tallow and ashes, the best with goats' fat and beech-ashes. It is of two kinds, the solid and the liquid. Both are employed by the Germans, but by the men more than by the women." In Arabian medicine soap was used to hasten the suppuration of boils, and, especially when mixed with honey, as a stimulant for ulcers; as a suppository to promote defecation; for washing leprous skins, and, with salt in a warm bath, to cure prurigo and ulcerated scabies; with oil to heal the salt rheum (eczema) of children's heads; with warm water to cleanse the scalp of dandruff and destroy nits and lice; and with "sandix" and slaked lime to dye the hair (*Ebn Baithar*).

Medical Action and Uses.—Soap acts upon quadrupeds (horses and dogs) internally very much as it does upon man—*i. e.* as mildly laxative and as weakly antacid through its alkaline constituent. But it is hardly ever used alone for these purposes, but rather to dissolve resinous medicines, along with which it is given, and thereby to quicken and strengthen their action. Pereira states that he knew of an idiot who had frequently eaten large lumps of soap without any ill effects, and that he had heard of a pound of it being swallowed for a wager.

Besides the use of soap as a *laxative*, it has been given internally as a solvent for uric acid. Along with calcined egg-shells (lime) and aromatic bitters it formed a once-famous cure for *gravel*; probably in this case it acted by giving up its acid to the lime and liberating the soda, which then tended to neutralize the free uric acid in the system. Soap is one of the best antidotes for *acid poisons*, because it is always to be promptly obtained, and because it does not itself act as an irritant. It should be given freely in the form of soapsuds. As a local remedy for external injuries by acids or by phosphorus soapsuds are efficient if promptly used.

As an external remedy soap acts by modifying the condition of the skin; it combines with the fat of the excretions, and removes them when they have grown acid or fetid, and, with them, the dirt accumulated from without; it softens the epidermis and removes its outer layers, and thus exposes the integument to the vivifying influence of the air; by all of which agencies a healthier condition of it is secured. If the soap be too strongly alkaline, or too little diluted with water, or applied with too active friction, it may induce painful irritation of the skin. This is particularly the case when there is added to the soap proper some article intended to exert a specific action, as sulphur, tar, etc. But in general the curative agent is used separately after the skin has been brought to a proper condition by warm water and soap. These remarks are particularly applicable to the treatment of *scabies, prurigo, psoriasis, acne, and eczema*. For this purpose soft soap is greatly to be preferred. In Germany, where the treatment of itch with soft soap

originated, it is now nearly abandoned, not only on account of the offensive smell and irritant properties of the preparation (green soap), but because the speedier and more agreeable cure by balsam of Peru and storax has superseded it. The stimulant action of soft soap is also resorted to in the treatment of *ichthyosis* and of *lupus*. The semi-liquid or liquid soaps have been much used as discutients of acute and chronic *glandular* swellings, whether of a simple or specific nature, and in serous effusions into *joints* (Senator, *Med. Record*, xxii. 711). A soft soap made with olive oil and pure solution of potassa is devoid of the offensive smell of ordinary soft soap, and is to be preferred when patients are delicate or fastidious, as in the case of ladies and children. It can be scented with an essential oil or dissolved in cologne-water. The ancient treatment of *boils* by soap continues to be used. In general, yellow soap, mixed with sugar and spread on leather or muslin, is applied to the part. So far from irritating it and causing greater pain, this remedy, when promptly resorted to, lessens the pain materially and hastens suppuration.

SAPONARIA.—SOAPROOT.

Radix saponariæ.—*Soapwort*, E.; *Saponaire*, *Savonnière*, Fr.; *Seifenwurz*, G.

The root of *Saponaria officinalis*, *Linne*.

Nat. Ord.—Caryophyllaceæ.

Origin.—Soapwort is a perennial herb growing throughout the greater part of Europe on the banks of streams and roadsides. It is sometimes met with in cultivation in gardens, and has been naturalized in North America. The stem is about 20 inches (50 Cm.) high; the leaves are opposite, mostly sessile, ovate, oblong or nearly lanceolate, three-nerved, entire, and nearly smooth. The large, pale rose-colored flowers are in corymbed clusters, have a cylindrical five-toothed calyx and five petals, with a two-cleft appendage at the top of the long claw. The herb flowers from June to August.

Description.—The root is collected in the spring or autumn without the creeping runners, is 10 to 15 inches (25–38 Cm.) long, cylindrical, about $\frac{1}{4}$ or $\frac{1}{2}$ inch (3–6 Mm.) thick, gradually tapering below, somewhat branched, longitudinally wrinkled, and of a red-brown color externally. It breaks with a short fracture, and is internally white, with a rather thick bark and a soft yellowish, and in the centre whitish, wood, which has no medullary rays and is surrounded by a fine dark-colored cambium-line. The root is inodorous, and has a sweetish and bitter afterward persistently acid taste.

Constituents.—Soaproot contains *saponin*, and is free from starch. Bucholz (1811) found also resin, mucilage, and other common principles. Osborne (1827) obtained from the root collected before flowering white, fusible, very bitter needles soluble in water, alcohol, and ether; but the nature of these has not been ascertained. Schiaparelli (1883) obtained saponin as a white, amorphous, inodorous powder, stermutatory and of a disagreeable taste, insoluble in ether, benzol, and chloroform, of the composition $C_{32}H_{54}O_{18}$, and by dilute acids split into glucose and *saponetin*, $C_{40}H_{66}O_{15}$. Saponin from quillaia-bark was found by Stütz to have the composition $C_{49}H_{80}O_{16}$. (See also QUILLAIA.)

Allied Drugs.—LEVANT SOAPROOT is obtained from *Gypsophila Struthium*, *Linne*, a caryophyllaceous perennial of Northern Africa and Southern Europe. It is 8 to 16 inches (20–40 Cm.) long, 1 to 4 inches (2–10 Cm.) thick, transversely and longitudinally wrinkled, brownish-yellow externally, internally white, with a rather hard wood and numerous medullary rays. In sensible properties and in composition it resembles the preceding.

SOAP-BERRIES are the fruit of *Sapindus Saponaria*, *Linne* (nat. ord. Sapindaceæ), a medium-sized tree of tropical America. They are the size of a cherry, globular or somewhat ovate, orange-colored, and contain a parchment-like endocarp enclosing two or three black seeds; the fleshy sarcocarp contains saponin and formic and tartaric acids. The fruit of the East Indian *Sap. laurifolius*, *Vahl*, is red-brown or blackish, and has similar constituents and properties. The seeds yield about 30 per cent. of a butyraceous fat.

Medical Action and Uses.—Saponaria has long enjoyed the reputation of being diaphoretic and diuretic, and alterative in that it cured chronic *diseases of the skin and bronchia*, *rheumatism*, *gout*, *syphilis*, and *periodical fevers*, or the *visceral engorgements* following them. It has been compared with sarsaparilla and with senega. It is administered in a decoction made with an ounce of the root to a pint (Gm. 32 in Gm. 500) of water. That this plant possesses active powers is evident from the large proportion it contains of saponin, whose peculiar virtues are treated of elsewhere. (See SENEGA.)

SARCOCOLLA.—SARCOCOLLA.

Sarcocolle, Fr.; *Fleischleimgummi*, *Fischleimgummi*, G.

An exudation of *Penæa Sarcocolla*, Linné, and *P. mucronata*, Linné.

Nat. Ord.—Penæaceæ.

Origin and Description.—The plants named are small branching shrubs, with small, opposite, entire, coriaceous leaves, and clusters of yellow flowers surrounded by a purplish-red leafy involucre. The shrubs are indigenous to Central and Southern Africa, and exude a juice which after hardening constitutes sarcocolla. Dymock (1879), however, noticed that the sarcocolla which comes in considerable quantities to Bombay from the Persian port of Bushire is always mixed with fragments of a thorny stem and with short, slender, and cottony pods containing a single gray-brown vetch-like seed; he believes that the gum is obtained from one of the desert Leguminosæ, probably a species of *Astragalus*. It is in small, roundish, somewhat spongy, and friable grains, which are sometimes agglutinated to larger masses, often mixed with fine hairs, and have a yellowish, reddish, or brownish color. Sarcocolla is inodorous, has an insipid, sweetish, afterward somewhat acid and bitter taste, resembling that of liquorice-root; is soluble in water, almost completely soluble in alcohol, except the impurities, and when heated burns and gives off the odor of burning sugar.

Constituents.—On treating sarcocolla with ether, Pelletier (1834) separated a resin; the undissolved residue yielded to alcohol *sarcocollin*, and left gummy matter behind. Sarcocollin is uncrystallizable, soluble in alcohol and water, possesses a bitter-sweet taste, and when oxidized with nitric acid yields oxalic acid. Its composition is stated to be $C_{13}H_{23}O_6$.

Medical Action and Uses.—The name of this substance, which means a healer of the flesh, it has borne since an early period in the history of medicine. It was held in great repute for agglutinating wounds and curing *defluxions of the eyes*, and was also applied to *joints* affected with chronic inflammation. It was reputed to be a *depilatory*, was used with honey to check *otorrhœa*, and was applied with nitre as a discutient of *scrofulous glands*.

SARRACENIA.—PITCHER-PLANT.

Side-saddle plant, *Huntsman's cup*, *Water cup*, E.; *Sarracenie*, Fr., G.

Sarracenia purpurea, Linné.

Nat. Ord.—Sarraceniaceæ.

Description.—This plant grows in boggy places from Canada southward. The *rhizome* is oblique, conical, about an inch (25 Mm.) or more long, of a reddish-brown color externally and brownish-white internally, has numerous, thin, nearly simple, toughish rootlets attached, breaks with a short fracture, and does not acquire a blue color with solution of iodine. It is inodorous, and has a bitter and somewhat astringent taste. The *leaves* are radical, 6 or 8 inches (15–20 Cm.) long, pitcher-shaped, most inflated near the middle, curved, broadly winged, with an erect, roundish, heart-shaped hood, and have a bitterish taste. The *flower* is nodding, globose, and deep-purple, and has fiddle-shaped petals.

Constituents.—The plant was analyzed by Björklund and Dragendorff (1863), who found, besides the usual constituents of herbs, *acrylic acid*, which is volatile, and about $\frac{1}{6}$ per cent. of a *volatile base* having an odor resembling that of conine. Stan. Martin (1865) announced the presence of a bitter alkaloid, *sarracénine*, the sulphate of which is crystallizable; and Hétet found two alkaloids, one of which had the properties of veratrine. E. Schmidt (1872) isolated a yellow coloring matter, *sarracénic acid*, which yields with alumina a yellow lake.

Allied Plants.—*SAR. FLAVA*, Linné, Trumpet-leaf. The *rhizome* is similar to the preceding, but larger. The *leaves* are about 2 feet (60 Cm.) long, tubular, gradually enlarged to the open throat, and have a very narrow wing and a roundish mucronate hood, which is narrowed toward the base. The flower is yellow. The plant grows in the Southern United States.

SAR. VARIOLARIS, Michx., grows from South Carolina to Florida, and has elongated leaves mottled with white on the back, with a linear wing, and with the lamina inflected over the throat of the tube. The flower is yellow.

Medical Action and Uses.—*S. flava* and *S. variolaris* possess stimulant and tonic virtues, for which they enjoy a high reputation in South Carolina, where they are used in the treatment of *dyspepsia* and its associated ailments. *Sarracenia* is said to have been employed in gout and rheumatism, and Hétet has claimed that it contains an alkali

identical with veratria (*Bull. de thérap.*, xvi. 178). A hasty and immature observation at one time ascribed to *S. purpurea* the virtues of a specific remedy for small-pox—a notion which, it is almost superfluous to say, was not confirmed by experience, but which, like other errors, it required some time and labor to destroy.

SARSAPARILLA, U. S.—SARSAPARILLA.

Sarsæ radix, Br.; *Radix sarsaparillæ*, P. G.—*Salseparille*, Fr.; *Sassaparilla*, G.

The root of *Smilax officinalis*, Kunth. Sm. medica, *Schlechtendal et Chamisso*, and of other species of *Smilax*. Bentley and Trimen, *Med. Plants*, 289, 290.

Nat. Ord.—Smilacæe.

Origin.—Sarsaparilla is obtained from different species of *Smilax* growing in swampy forests of Mexico and as far south as the northern portion of Brazil. These are woody climbers, and often attain a great height. *Smilax Sarsaparilla*, Linné, is indigenous to the United States, and grows chiefly in the Southern States; it is in part at least *Smilax glauca*, Walter, but does not afford any sarsaparilla; its subterranean portion is a long, cylindrical, creeping rhizome with prominent nodes and a few small rootlets, and bears no resemblance to the commercial drug. The only sarsaparilla-yielding species which are tolerably well known are the following:

SMILAX OFFICINALIS. It is indigenous to New Granada and other parts of Northern South America, and has a quadrangular stem and large cordately-ovate or oblong, five- or seven-nerved leaves; it furnishes Jamaica sarsaparilla.

SMILAX MEDICA. It has a zigzag stem and much smaller leaves, which are frequently auriculate, with broad and obtuse basal lobes. It is indigenous to Mexico, and affords the Mexican sarsaparilla.

SMILAX SYPHILITICA. Kunth, *S. scabriuscula*, Kunth, *S. cordato-ovata*, Richard, *S. papyracea*, Poirét, *S. Purhampuy*, Ruiz, and others, seem to be imperfectly known, or, at all events, it is uncertain whether they are sources of some variety of the drug.

Collection.—No satisfactory account has been given of the manner in which the different varieties are collected and prepared for the market. According to Rich. Spruce, in the valley of the Amazon the roots are about 9 feet (2.7 M.) long, spread horizontally, and are collected after several stems have been produced, younger plants having so few roots as not to be worth grubbing up. The earth is scraped away from the roots by

FIG. 250.

Transverse and longitudinal section of Sarsaparilla: *a*, epidermis; *b*, subcuticular tissue; *c*, parenchyma; *d*, nucleus-sheath; *e*, woody zone; *f*, central parenchyma.

hand, aided by a pointed stick, and the roots of other plants interfering are cut through with a knife. When at length laid bare, the sarsaparilla-roots are cut off near the crown, a few slender ones being allowed to remain to aid the plant in renewing its growth, and the stems are cut down to near the ground. The yield of a plant of four years' growth is about 16 pounds, and of older plants from two to four times that quantity (*Pharmacographia*). During the year 1876, 883,590 pounds of sarsaparilla were imported into the United States, but the average importation during eight years, including 1883, was only 484,010 pounds.

Description.—As met with in commerce, sarsaparilla consists either of the horizontal roots alone or in part also of the short knotty rhizome, to which, in some sorts, portions of the overground stems are sometimes attached. The roots are long, cylindrical, tapering toward both extremities, and beset with thin branching fibres called the *beard*, or nearly free from fibres. They are more or less deeply furrowed in a longitudinal direction, and have mostly a gray or blackish-gray color externally from adhering earth, and after this has been washed off are of a bright brownish- or reddish-yellow color, and partic-

ularly in the folds are often clothed with short simple hairs. When cut transversely several distinct zones are observed, which, under the microscope, have the following appearance: The epidermis is formed of one layer of cells, some of which are prolonged

into hairs; then follows the outer endoderm, a subcuticular layer composed of two or three or more rows of axially-elongated cells with their walls thickened from secondary deposits, and a layer of parenchyma, called the *bark*, and containing starch or an amorphous mass, and some cells filled with bundles of needle-shaped crystals consisting of oxalate of calcium. Underneath the bark is the nucleus-sheath, also called bundle-sheath and inner endoderm, consisting of a single row of cells with thickened walls, resembling those of the subcuticular tissue, and varying in shape and in the secondary deposits in the differ-

FIG. 255.

Honduras Sarsaparilla.

FIG. 256.

Honduras Sarsaparilla, 3 diameters.

ent varieties; to this adheres the *woody zone*, varying in width in the different kinds, and chiefly composed of fibro-vascular bundles. The central layer, usually called the *pith*, consists of parenchyma-cells similar to those outside the nucleus-sheath, and occasionally contains a few scattered wood-bundles. Schleiden, and afterward Berg, proposed a classification of the sarsaparillas mainly from the character of the nucleus-sheath, and more recently a similar view was taken by Ferd. Otten (1876). The cells of the nucleus-sheath are nearly uniformly thickened on all sides, and have an almost quadrangular appearance in Honduras sarsaparilla; they are somewhat elongated in a radial direction in Brazilian sarsaparilla, and toward the outside are rather less thickened than on the inner and lateral cell-walls. Mexican sarsaparilla has the cells of the nucleus-sheath of a somewhat wedge-shaped appearance, the layers of the cells-walls being thickest in the inner half. Jamaica sarsaparilla has the incrustation of the sheath-cells thickest upon the inner and lateral walls—frequently so as to assume a wedge-shaped appearance; another kind has the cells radially elongated, but not wedge-shaped, and the cell-walls nearly uniformly thickened on all sides. There are, however, frequently modifications or intermediate forms of these characters observed. The cells of the subcuticular layer have their cell-walls considerably thickened, particularly the outer ones.

Sarsaparilla is nearly inodorous, except in infusion and decoction; it has at first a slight taste, but leaves an acrid impression in the fauces, by the intensity of which the quality of the root may be approximately judged.

Commercial Varieties.—The sarsaparillas may be conveniently distinguished as *mealy* and *non-mealy*; the former are amylaceous in the interior, but usually contain in some portions of the parenchyma-tissue amorphous masses of altered starch, and they are usually marked externally by rather uniform and shallow wrinkles. The non-mealy varieties are rather horny, and not farinaceous when broken transversely, contain but little granular starch, and are usually characterized by deep longitudinal and irregular

folds. The sarsaparillas from Honduras and Mexico, which are mostly met with in the United States, are representatives of the two classes.

FIG. 257.

Rio Negro or Para Sarsaparilla.

Mealy Sarsaparillas.—HONDURAS SARSAPARILLA. This is exported from Belize and other ports on the Bay of Honduras, and comes in bundles 2 or 3 feet (60 to 90 Cm.) long, consisting of the folded roots, in the interior containing some hard woody rhizomes and often short fragments of the stem, and tied with roots of the same kind. The roots have some fibres attached, and have the cortical layer somewhat thicker than the woody zone, and of about the same width or thinner than the pith. It is the kind recognized by the German Pharmacopœia.

RIO NEGRO SARSAPARILLA, also called *Para*, *Brazilian*, and *Lisbon Sarsaparilla*. This is exported from Para, and comes in long cylindrical rolls tied together by a smooth stem, and with both ends cut off evenly. It is free from rhizomes and stems, and contains but few root-fibres, but the interior of the bundle is frequently packed with roots of inferior quality. The bark and pith are nearly of the same width, but the ligneous zone is only one-third or one-fourth that thickness.

Non-mealy Sarsaparillas.—MEXICAN SARSAPARILLA, also called *Vera Cruz* and *Tampico Sarsaparilla*. The roots are folded back, so as to cover the knotty rhi-

FIG. 258.

Rio Negro Sarsaparilla, 3 diameters.

FIG. 259.

Mexican Sarsaparilla.

FIG. 260.

Mexican Sarsaparilla, 3 diameters.

zomes and portions of the stem, which are often 6 inches (15 Cm.) in length. The roots have but few rootlets attached, and are deeply and irregularly wrinkled. The pith is of about the same width as the woody zone or a little thicker, but the bark is sometimes twice this thickness, at least in the projecting ridges or after soaking in water. It is probably obtained from *Smilax medica*.

JAMAICA SARSAPARILLA. This is also known as *bearded sarsaparilla*, from the numerous root-fibres attached to it. It comes in bundles similar to, but usually shorter than, those of Honduras sarsaparilla, and less neatly tied. The rhizomes are generally absent. The layers of pith and bark are nearly of the same width, but the woody zone is narrower, being about one-half the width of the pith. It varies in mealliness, often in different parts of the same root, and is also distinguished from the other varieties by its reddish-brown color. It does not grow wild in Jamaica,

FIG. 261.

Jamaica Sarsaparilla.

FIG. 262.

Jamaica Sarsaparilla, 4 diam.

but is obtained from Costa Rica, and a similar drug, agreeing in all essential qualities with

this, is sometimes exported from Venezuela and known as *Caracas sarsaparilla*. It is supposed to be derived from *Smilax officinalis*, which is cultivated to a limited extent in Jamaica, but there furnishes a more mealy root. Jamaica sarsaparilla is the only kind recognized by the British Pharmacopœia.

Other varieties of sarsaparilla have been described by European writers, but are rarely, if ever, met with in commerce in this country.

Constituents.—Sarsaparilla was analyzed by Pallotta (1824), Folchi, Thubeuf (1831), Batka (1834), Poggiale (1835), and others, and the acrid principle has at different times received the designations *smilacin*, *pariglin*, *parillin*, *salsaparin*, etc. Pallotta precipitated the decoction with milk of lime, decomposed the precipitate with carbonic acid, and, after drying, exhausted it with alcohol. Thubeuf exhausted the root with boiling alcohol, concentrated the tincture, treated the residue with charcoal, and recrystallized from hot alcohol; 10 pounds of the root yielded 3 ounces of smilacin. Lamatsch (1857) precipitated the concentrated alcoholic decoction with water, washed the precipitate with ether, and purified it by treating its alcoholic solution with animal charcoal; Flückiger (1877) recrystallized this precipitate from alcohol; the yield was 0.19 per cent. In its purest state parillin has been obtained as colorless needles, which are sparingly soluble in cold water and diluted alcohol, but more freely soluble in hot water (20 parts, Flückiger) and hot alcohol; it is also soluble in alkalies and dilute acids, and nearly insoluble in ether and chloroform. Its aqueous solution foams in a manner similar to that of a solution of saponin, and on boiling reduces in a slight degree an alkaline solution of copper, but more abundantly after it has been boiled with dilute sulphuric acid, when sugar and *parigenin*, which is insoluble in water, are formed. Parillin is precipitated by lead acetate and subacetate and by tannin, dissolves in sulphuric acid with a yellow afterward cherry-red color, and with warm diluted sulphuric acid turns greenish, red, and brown; it appears to be closely related to sapogenin, but its exact composition has not been determined. The other constituents of sarsaparilla are a trace of essential oil, resin, pectin, albumen, and other common principles. Otten obtained also between 2 and 3 per cent. of *saponin*, and determined the starch in the non-mealy varieties to vary between 3 and 13.8 per cent., while the mealy varieties contained sometimes as high as 15 per cent., and in rare cases as low as 10, or even 6.25, per cent. of starch.

Valuation.—Marquis (1875) estimated the amount of (impure) parillin by digesting the root with 30 per cent. alcohol, evaporating to an extract, washing this with cold water, and exhausting with boiling alcohol, on the evaporation of which a yellowish mass was left, which was weighed as parillin. After modifying the process, Otten obtained similar results, tending to show that Honduras and Para sarsaparilla yield less parillin than the Vera Cruz and Jamaica varieties.

Allied Drugs.—*SMILAX CHINA*, *Linné*. This is a climbing shrub of Eastern and South-eastern Asia. Its irregular, tuberous rhizomes, together with those of several other species, are used in Europe as *Rhizoma (Radix) Chinæ*.—China-root, *E.*; Squine, Racine de Chine, *Fr.*; China-wurzel, *G.*—They vary in length from 4 to about 10 inches (10–25 Cm.), and in thickness from 1 to 2 inches (2–5 Cm.), are more or less covered with short obtuse branches, are reddish-brown and somewhat wrinkled externally, and internally brownish-white, with numerous brown resin-spots, somewhat horny or mealy, hard, and dense. China-root is inodorous and has an insipid, faintly bitter, and somewhat acrid taste. *Smilax Pseudo-china*, *Linné*, and *Sm. tannoides*, *Linné*, which are natives of the United States, yield similar tuberous rhizomes, which are usually lighter in color and weight. The root of *Sm. aspera*, *Linné*, of Southern Europe, has been employed there in place of sarsaparilla.

The Mexican Pharmacopœia recognizes as *raiz de China de Mexico* a large conical or somewhat spindle-shaped root, which is 18 inches (45 Cm.) long, 6 or 7 inches (15–18 Cm.) in diameter, reddish-brown, internally lighter, fleshy, with numerous irregular wood-bundles, inodorous when dry, and of an astringent and somewhat bitter taste. It is erroneously referred to *Smilax rotundifolia*, *Linné*, which is indigenous to the United States and has a creeping rhizome with prominent nodes.

CAREX ARENARIA, *Linné*.—Sand sedge, German sarsaparilla, *E.*; Laiche, *Fr.*; Sandriedgras, Rothe Quecke, *G.* (nat. ord. Cyperaceæ).—It is indigenous to Europe, and grows frequently in sandy soil and near the coast of Germany. The rhizome (*Rhizoma caricis*) is creeping, several feet long, about $\frac{1}{10}$ inch (2.5 Mm.) thick, subcylindrical, gray-brown, wrinkled, and on the nodes beset with rootlets and with fringed sheaths. Internally, it shows a woody zone composed of three irregular circles of fibro-vascular bundles enclosing soft white cellular tissue, and surrounded by a cortical layer having a circle of large prominent air-passages. The dried rhizome has little odor and a mealy, sweetish, afterward bitter and acrid taste. It is employed like sarsaparilla.

Off. Prep.—Decoct. sarsæ, *Br.*; Decoct. sarsaparillæ (sarsæ) comp., Extract. sarsapa-

riellæ fluid. (sarsæ liquidum), *U. S., Br.*; Ext. sarsaparillæ fluid. comp., Syrup. sarsaparillæ comp., *U. S.*

History.—The Spaniards first brought sarsaparilla to Europe about the middle of the sixteenth century from Peru, St. Domingo, and Brazil. It was then believed to be a specific for constitutional syphilis, and especially for the rheumatoid and ulcerative symptoms of that disease. It had, however, quite fallen into neglect when a belief in its virtues was for a time revived at the end of the eighteenth century; but it again gradually lost confidence as a remedy for syphilis, and was more largely used by nostrum-venders than by physicians.

Physiological Action.—The operation of the active principle of this root (smilacin, parillin) is by no means a negative one. According to Pallotta, in doses of 6 grains it occasions malaise and slowness of the pulse; 8 grains produce nausea and constriction of the throat; 10 grains, general debility and diaphoresis; 13 grains, moderate vomiting of a bitter liquid, with irritation and constriction of the throat, faintness, and general exhaustion. These effects have been ascribed to a different principle from either of the above, but which has not been isolated. It is certain, however, that they may be caused by some derivative of sarsaparilla, however named, and that they have also been produced by large doses of the drug itself. In medicinal doses neither sarsaparilla nor its usual preparations occasion any such phenomena. Their effects are manifested during a state of disease, rather than in health, and consist of an improved condition of the digestive and nutritive functions and the gradual subsidence of the morbid derangement.

Medical Uses.—Although sarsaparilla has been recommended in chronic *gout, rheumatism, and skin diseases*, yet the only disease for the cure of which special virtues have been claimed for it is constitutional *syphilis*, and the most eminent authorities upon this subject have generally agreed that its efficacy depends upon the patient having been previously subjected to a mercurial treatment. It is certain that with the disuse of mercury to produce salivation, and the dire consequences of the saturation of the system with that mineral, the use of sarsaparilla grew less and less frequent, so that it at last came to be prescribed, not so much from a belief in its utility as to gratify the popular faith in its virtues. Some have gone so far as to declare that the various decoctions of sarsaparilla are curative solely by means of the water which they contain—a judgment which, in view of the powers manifested by its active principles, seems to be exaggerated, if not erroneous. It is the more difficult to determine the value of sarsaparilla in the treatment of syphilis because it is nearly always associated with other active medicines, as with guaiacum and mezereon in the compound decoction, and with the former of these drugs in the compound syrup of sarsaparilla. Of the official preparations, the first is the only one that is worthy of being used. It is customary to associate with it iodide of potassium, which is commonly curative without the sarsaparilla. Nevertheless, there are cases of constitutional syphilis which make no progress or grow worse under treatment by mercury or by iodine, and which are restored to health by the decoction of sarsaparilla (*e. g.* two cases by Carter, *Practitioner*, xxvi. 357).

Zittmann's decoction for the cure of syphilis is one of the most celebrated and efficient preparations of sarsaparilla. It is composed of two decoctions, a stronger and a weaker. The former is prepared as follows: Take 12 ounces of clipped sarsaparilla and 72 pints of water, and allow them to digest for 24 hours; then add 5vj each of powdered sugar and alum, and in a covered vessel expose to a steam-bath until the liquid is reduced to 24 pints. Toward the close of the operation add anise and fennel, of each 3ss, of senna 3iij, and of sliced liquorice-root 3iss. Press and strain, and when the decoction is cool decant the clear liquid and bottle 24 pints. In the original formula, besides the sugar and alum, there were added 3ss of calomel and 5j of sulphuret of mercury enclosed in a linen bag, and allowed to remain in the liquid during the boiling, which furnished to it a very minute proportion of corrosive sublimate. The weaker decoction is prepared by adding to the dregs of the stronger decoction of fresh sarsaparilla 5vj and 72 pints of water, and boiling as before, but toward the end of the ebullition are introduced 5iij each of lemon-peel, cinnamon, and liquorice-root. In using this mode of treatment, which lasted from two to four weeks, the patient was required to live on a mild diet and drink of the stronger and weaker decoctions alternately: *e. g.* every morning from 10 to 16 fl3 (Gm. 300–500) of the former, and every evening the same quantity of the latter, or morning and evening a like quantity of the stronger decoction, but warm at the one time and cold at the other, and between the two an equal quantity (Oij) of the weak decoction. Of the virtues of this preparation we have the authority of Erasmus Wilson for saying that in extreme and very obstinate cases of the ulcerating forms of

syphilis which have resisted both mercury and iodine, and particularly in those most difficult of all cases where the disease has got possession of the tongue and the mucous membrane of the mouth, it may often be had recourse to with great success.

CAREX ARENARIA was at one time regarded as possessing all the virtues of sarsaparilla, and particularly as promoting the cutaneous and renal secretions. It was used in the treatment of *rheumatism, gout, pulmonary and cutaneous diseases, and syphilis*. The root was used in the decoction, and in its stead *C. intermedia* and *C. hirta* were often employed.

ARENARIA RUBRA is a popular remedy in Algiers for *gravel* and various affections of the urino-genital organs and in some forms of dropsy. It is said to be entirely innocuous. It probably owes its diuretic qualities to the large proportion it contains of sodium and potassium salts. It is best given in a decoction prepared with an ounce of the plant in a pint of water, reduced one-fifth, and sweetened. *Dose*, a tablespoonful six or seven times a day (*Bull. de thérap.*, xcv. 287; xevii. 69, 94).

SASSAFRAS, U. S.—SASSAFRAS.

SASSAFRAS MEDULLA, U. S.—SASSAFRAS-PITH.

The bark of the root (the root, *Br.*, *P. G.*) and the pith of *Sassafras officinalis*, *Nees*, *s. laurus* (*Persea*, *Sprengel*) *Sassafras*, *Linné*. Bentley and Trimen, *Med. Plants*, 220. *Nat. Ord.*—Lauraceae.

Origin.—Sassafras became known in Europe toward the close of the sixteenth century. The plant is indigenous to North America from Canada southward to the Gulf of Mexico and westward to Texas; remains shrubby in the north, but attains a height of 40 or 50 feet (12–15 M.) in the Southern States. The trunk has a rough furrowed gray bark, but the young branches are of a brown color. The wood is white or reddish, light, but very strong and durable. The leaves are alternate, petiolate, 3 or 6 inches (7–15 Cm.) long, bright-green and smooth above, downy beneath, especially when young; broadly ovate in shape and entire, or some of them two- or three-lobed—all, however, with a wedge-shaped base. The greenish-yellow flowers appear before the leaves in March and April or May, are dioecious, grow in downy racemes, and have linear bracts at the base and a deeply six-lobed perianth. The male flowers have nine stamens in three rows, and the female flowers six short imperfect stamens. The fruit is a dark-blue, oval or ovoid, one-seeded drupe, supported in the permanent base of the perianth and on the thickened clavate reddish peduncle. The flowers have an agreeable though not a strong odor; the bark of the branches is aromatic, but differs in flavor from that of the root; the leaves contain a considerable quantity of mucilage.

Description.—The following parts are recognized by the pharmacopœias:

1. SASSAFRAS, U. S.; CORTEX SASSAFRAS.—Sassafras-bark, *E.*; Écorce de sassafras, *Fr.*; Sassafrasrinde, *G.*—Only the root-bark is employed. It is deprived of the dark-gray, inert, corky layer, is whitish in the fresh state, and is seen in commerce in irregular flattish or curved pieces, usually 2 to 4 inches (5–10 Cm.) in length and width. It is of a bright rust-brown color, on the inner surface finely striate and glistening, rather soft and fragile, breaks with a short corky fracture, and on transverse section is radially striate. It has a strong fragrant odor and a sweetish, aromatic, somewhat astringent taste.

2. SASSAFRAS RADIX, *Br.*; Lignum sassafras, *P. G.*—Sassafras-root, *E.*; Bois de sassafras, *Fr.*; Sassafrasholz, Fenchelholz, *G.*—The root is medicinally employed in Europe, but not in the United States. It comes in crooked and branching pieces with or without the bark attached, varying in size, and in color between yellowish-white and pale-brownish or reddish. The wood is rather spongy, porous, light, composed of numerous annual layers and marked by numerous medullary rays; it has the odor and taste of the bark, but in a milder degree. The German name *Fenchelholz* (fennel-wood) has reference to the fancied resemblance of its odor to that of fennel.

3. SASSAFRAS MEDULLA, U. S., Sassafras-pith. It is obtained from the branches, and is met with in slender, cylindrical, very light pieces, frequently curved or coiled, white, inodorous, and of an insipid, mucilaginous taste. When macerated in water it forms aropy but non-tenacious mucilaginous liquid, which is not precipitated by alcohol.

Constituents.—Sassafras-bark was examined by Reinsch (1845), who obtained from it volatile oil (page 1086), tannin, sassafrid, starch, resin, waxy matter, mucilage, and coloring matter. On treating the bark, previously exhausted by ether, with alcohol,

evaporating the alcohol, and macerating the extract with water, *tannin* is dissolved, yielding with ferric salts bluish-green precipitates, and *sassafrid* remains behind as a light reddish-brown, inodorous, and nearly tasteless powder, which is nearly insoluble in ether, and separates from its hot concentrated alcoholic solution in yellowish-brown crystalline granules. Its solutions are colored red by alkalis, and precipitated carmine-red by alkaline earths, dark greenish-brown by ferric salts, and whitish by acetate of lead. It is doubtless an oxidation-product of tannin. Pectin could not be found. The bark contains about 6 per cent. of tannin and over 9 per cent. of sassafrid. According to Procter (1866), fresh sassafras-bark contains no sassafrid, but this is formed from the tannin on exposure to air. The woody portion of the root contains the same constituents, but in smaller proportion. The principal constituent of sassafras-pith is *mucilage*.

Off. Prep.—1. *Of the bark and root*: Decoct. sarsaparillæ (sarsæ) comp., *U. S.*; *Br.*; Extract. sarsaparillæ fluidum comp., *U. S.*; Species lignorum, *P. G.* 2. *Of the pith*: Mucilago sassafras, *U. S.*

Allied Plant.—UMBELLULARIA (OREODAPHNE, *Nees*, TETRANTHERA, *Wight & Arnott*) CALIFORNICA, *Nuttall*, California bay-laurel or spice tree. This evergreen tree is indigenous near the Pacific coast of North America, and in Oregon attains a height of 80 feet (24 M.) or more, but in California is of smaller size. The brownish close-grained wood is much esteemed for cabinet-work. The leaves are alternate, lanceolate, entire, pinnately veined, reticulate, and pellucid punctate. They yield about 4 per cent. of a yellowish volatile oil having the spec. grav. .936, an odor resembling nutmeg and cardamom, and a warm camphoraceous taste. The oil was examined by J. P. Heany (1875) and J. M. Stillman (1880), and appears to contain a hydrocarbon and a terpene-hydrate, $C_{20}H_{32}.H_2O$, boiling below $190^{\circ}C.$ ($374^{\circ}F.$), and *oreodaphnol* (umbellol, Stillman), $C_8H_{12}O$, boiling above $210^{\circ}C.$ ($410^{\circ}F.$). The seeds contain a fat which melts near $32^{\circ}C.$ ($89^{\circ}F.$), and, according to Stillman (1882), contains crystalline *umbellutic acid*, $C_{11}H_{22}O_2$, distilling near $272^{\circ}C.$ ($522^{\circ}F.$) without decomposition.

Medical Action and Uses.—Sassafras-bark is believed to be somewhat stimulant, quickening the pulse slightly, promoting digestion, and increasing the secretions of the skin and kidneys. It was formerly used in the treatment of chronic *syphilis* and diseases of the *skin*, and is one of the medicines which are popularly supposed to purify the blood. Its real virtues, if any, are undetermined. It may be given *ad libitum* in an infusion made with from $\frac{1}{2}$ ounce to an ounce of the bark and $\frac{1}{2}$ pint (Gm. 16–32 in Gm. 250) of hot water. It is said that an infusion of sassafras-bark is “almost a specific for the rash produced by poison oak.” It should be taken internally and applied topically (Hinton).

Sassafras-pith is used to form a mucilage with cold water. It is demulcent, and at the same time a very mild local stimulant. An infusion of it may be used internally as a drink in *dysentery*, in inflammations of the *throat*, *air-passages*, and *stomach*, and in febrile affections generally. It forms an agreeable and efficient collyrium in cases of acute *conjunctivitis*, and serves as a vehicle for more active remedies.

SAURURUS.—LIZARD'S TAIL.

Saururus cernuus, *Linné*.

Nat. Ord.—Saururacæ.

Description.—This is a common North American perennial, inhabiting swampy localities. Its stem is about 2 feet (60 Cm.) high and rather weak. The leaves are alternate, petiolate, about 4 inches (10 Cm.) long, heart-shaped, entire, pointed, convergingly ribbed, slightly hairy, and underneath pale-green. The flowers are in a slender, crowded, terminal, spike-like raceme which is about 4 inches (10 Cm.) long, are destitute of any floral envelope, contain six hypogynous stamens and three or four ovaries united at the base, and produce a somewhat fleshy berry-like fruit. The entire plant has an aromatic but rather unpleasant odor and a somewhat acrid taste.

Constituents.—The plant has not been analyzed.

Allied Plant.—ANEMOPSIS CALIFORNICA, *Hooker*. It is a small perennial, indigenous to California and Mexico, where it is known as *yerba mansa*. The leaves are mostly radical, smooth, and have sheathing petioles; the root is whitish and fleshy; all parts of the plant, when broken, have a pungent peppery taste. Prof. Lloyd (1880) obtained from a pound of the root 6 drachms of a yellowish volatile oil, which becomes red and thick with sulphuric acid, is slowly colored blue, violet, purple, and brown by hydrochloric acid, and acquires a blue color with nitro-muriatic acid. Alcohol deprives the root of its sensible properties, and when evaporated leaves an oil which is heavier than water, and from which carbon disulphide precipitates a brown granular substance having an astringent and peppery taste and being soluble in dilute alcohol and in glycerin.

Medical Action and Uses.—The root is used in poultices as an application to *abscesses* and other painful swellings, and a decoction of it is sometimes employed in *strangury* and other irritations of the urinary passages and bowels. It is also directed in a strong infusion, of which several ounces should be continuously given at short intervals when the symptoms are urgent.

SCAMMONIÆ RADIX, *Br.*—SCAMMONY-ROOT.

Racine de scammonée, Fr.; *Scammoniawurzel, G.*

SCAMMONIUM, *U. S., Br.*—SCAMMONY.

Scammonée, Fr.; *Scammonium, G.*

The root and the resinous exudation from the root of *Convolvulus Scammonia*, *Linneé*. Bentley and Trimen, *Med. Plants*, 187.

Nat. Ord.—Convolvulaceæ.

Origin.—The scammony-plant is an herbaceous twining perennial growing in Syria, Asia Minor, and Greece; it has alternate, triangular-cordate, very acute leaves, large, funnel-shaped, pale-yellowish flowers, and ovate-globose capsules containing four angular seeds.

Description.—1. SCAMMONY-ROOT. It is 20 to 40 inches (.5–1 M.) in length, after drying about 2 inches (5 Cm.) thick in the upper part, cylindrical, somewhat tapering below, more or less twisted, with several short stem-fragments at the crown, longitudinally wrinkled, of a grayish- or yellowish-brown color externally and grayish or brownish-white within. The root is hard, has but a slight odor, and a sweetish afterward acrid taste, and upon transverse section shows a thin bark about one-eighth or one-sixth the diameter of the root, and, like the parenchyma of the medullium, containing numerous resin-dots, the concrete latex of the milk-vessels; the wood consists of a number of separate groups of wood-bundles varying in thickness, irregularly arranged, and separated from one another by parenchyma of variable thickness.

2. SCAMMONIUM. This is collected by laying the upper portion of the root bare, cutting the top off in an oblique direction, and collecting the milk-juice in shells, the contents of which are mixed together with the juice scraped from the root and dried. Scammony is met with in commerce in irregular angular pieces or circular cakes of a greenish dark ash-gray or dark-brown nearly black color, of a peculiar sour and somewhat cheese-like odor, and of a slight but distinctly acrid taste; it breaks readily with an angular or splintery fracture, and exhibits in the interior small fissures and cavities and a resinous lustre. When triturated with water it yields a greenish emulsion; its powder has a gray or greenish-gray color. It yields to alcohol or ether not less than 75 (*U. S.*), and sometimes as much as 95, per cent. of its weight, and when the solvent has been evaporated and the resinous residue dissolved in warm solution of potassa, no precipitate is produced on the addition of an acid. The portion left undissolved by alcohol or ether is of a gray color, and is not colored blue by iodine.

The best quality of scammony is known in commerce as *virgin scammony*. Of late years scammony is usually sold in the market, at least at wholesale, by the amount of resin it contains—a commendable custom which we believe has been introduced in this country through the efforts of Dr. E. R. Squibb. 766 pounds of scammony were imported in the year 1876–77, and 2942 pounds in 1883.

Adulterations.—A distinction has been sometimes made between *Aleppo* and *Smyrna* scammony, the former being regarded as the pure article, but we have seen in commerce scammony sold as one or the other kind which was very impure. The adulterations usually consist of farinaceous substances, chalk, and earthy material, which can easily be recognized by their insolubility in ether. Scammony thus adulterated is frequently smooth externally, dense, heavy, and effervesces when thrown into dilute hydrochloric acid, or its decoction with water yields a blue color on the addition of iodine. M. Conroy (1883) reported an adulteration consisting of the resin prepared from scammony-root, which is recognized by its distinctive persistent leathery odor.

A factitious scammony has been described by European writers as *Montpellier scammony*, and is said to be the milk-juice of *Cynanchum monspeliacum*, *Linneé*, mixed with other substances. It is said to have been occasionally imported into this country. Though it may be made to resemble true scammony in appearance, it does not show the behavior to solvents described above.

In place of scammony-root, we have seen a thin farinaceous root offered, which resembled turpeth-root (page 847), but was not identical with it.

Constituents.—Scammony-root is stated to be richest in resin immediately before the flowering period. Good roots will yield about 5 per cent. of resin. Hager found 10 per cent. of resin, 3 per cent. of tannin, and 15 per cent. of sugar and extractive; starch is likewise present. According to the British Pharmacopœia, scammony should contain between 80 and 90 per cent. of resin. The pure resin has been named *scammonin*; its composition, derivatives, and relation to allied resins have been described on pages 847 and 1300.

Off. Prep.—1. *Of the root*: Resina scammonii, Br. 2. *Of scammony*: Confectio scammonii, Pil. colocynthidis comp., Pil. colocynth. et hyoseyami, Pulv. scammonii comp., Br.; Resina scammonii, U. S., Br.

History.—Scammony, or at least the concrete juice of a *Convolvulus*, was well known to the Greek, Latin, and Arabian medical writers, who agree in ascribing to it active irritant and purgative qualities. It was used externally in the treatment of cutaneous diseases and in a tampon to provoke abortion. As a purgative they describe its harsh, painful, and exhausting action and its cholagogue qualities, and mention that it may produce cold sweats, syncope, and even death. To guard against its violent operation they advised that it be associated with certain gums, oils, mucilage, etc.

Physiological Action.—No other purgative is so uncertain as scammony, partly in consequence of its adulteration with inert substances, and in part from its slight solubility in the gastro-intestinal contents when these are acid. According to Rutherford and Vignal, it is a cholagogue of feeble power. It is singular that while in some experiments upon animals it occasioned active, exhausting, and even fatal purgation, yet in others it inflamed the bowels and killed the animals without purging at all. The actions of jalapin and convolvulin or scammonin are said to be identical. Careful experiments show that scammonin is a less active cathartic than scammony itself, unless finely divided by trituration. It appears also that in the case of both very slightly greater effects are obtained by a large increase of the dose—a result doubtless due to the imperfect solubility of the medicine. This is said to be increased by the presence of bile. That its active principle is absorbed appears from the following case: A healthy woman, nursing a healthy child two months old, took a dose of scammony to relieve herself of constipation; she suffered no purgation or any other symptoms attributable to the medicine, but her child was presently seized with violent cholera morbus, which rapidly ended in collapse and death (*Bull. de thérap.*, lxxv. 554).

Medical Uses.—Scammony is hardly ever used alone at the present day, although, on account of its tastelessness, it has been recommended as a purgative for children. Even in the cases to which it has been thought to be peculiarly applicable as a hydragogue, colocynth, jalap, and even gamboge, are to be preferred, and the same may be said in regard to its association with calomel as a cholagogue purgative. The compound powder of scammony is possibly preferable to scammony or to jalap alone when a powerful derivative action from the brain is desired.

The dose of ordinary scammony is from 10 to 20 grains (Gm. 0.60–1.30), and of pure scammony or of its resin from 5 to 15 grains (Gm. 0.30–1). It may be given powdered in a wafer, but is inactive in the pilular form. It is also administered in emulsion with milk, almond milk, mucilage, or other demulcent sweetened.

SCILLA, U. S., Br.—SQUILL.

Bulbus scillæ, P. G.—*Squills*, E.; *Scille*, *Squille*, Fr.; *Meerzwiebel*, G.

The bulb of *Urginea Scilla*, *Steinheil*, s. *Scilla* (*Urginea*, *Baker*) *maritima*, *Linneé*. *Nat. Ord.*—*Liliaceæ*.

Origin.—The squill is indigenous to the basin of the Mediterranean from Syria westward to the coast of the Atlantic. It grows in sandy and sunny places near the seashore, but is likewise found inland to some extent and in hilly localities. Two varieties are known, which differ only in the color of their bulb-scales, being of a reddish tint in the one and whitish in the other variety. The leaves make their appearance during the flowering period, and are broad-lanceolate, 12 to 20 inches (30–50 Cm.) long, channelled, finally recurved and spreading. The scape attains a height of 3 or 4 feet (.9–1.2 M.), and is terminated by a long raceme of whitish green-nerved flowers with six stamens inserted on the base of the sepals. Along the Mediterranean the bulb is frequently

employed in the fresh state, but in the United States it is now usually seen in dry segments. 12,213 pounds of squill were imported in 1878, and 54,365 pounds in 1883.

Description.—The bulb of squill is broadly ovate or somewhat pear-shaped, and is from 3 to 6 inches (7–15 Cm.) long, and of the same thickness at its lower portion, weighing sometimes over 4 pounds. It consists of a large number of fleshy scales, which are either whitish or reddish, and are covered by dry reddish-brown and scarious scales. The bulb is collected while leafless, about the month of August, freed from the inert outer and small, insipid central scales and from the dense stem portion and rootlets, and then cut transversely into segments, which are dried in the sun. Thus prepared, it is found in the market, and consists of narrow slices $\frac{1}{8}$ to $\frac{1}{4}$ inch (3–6 Mm.) wide and 1 or 2 inches (2–5 Cm.) long, somewhat translucent, yellowish-white or reddish, brittle and pulverizable when dry, but very hygroscopic, and therefore often flexible. Squill is scentless, and even in the fresh state is but slightly odorous; it has a mucilaginous afterward bitter and acrid taste. When dried and powdered it is easily converted into a solid hard mass from the absorption of moisture. In damp weather squill loses on drying from 10 to 14 per cent. of its weight. On handling squill it is apt to cause irritation of the skin, due to the sharp-pointed raphides of calcium oxalate.

Constituents.—Squill has been frequently the subject of chemical investigation, but even at the present time the medicinally important principles of this drug are not satisfactorily known. Two such principles are usually distinguished: one, having a bitter taste, is called *scillitin*; the other, being acrid, has received the name *skulein*. Wittstein (1850) observed that the expressed juice of fresh squill yields with alcohol a precipitate consisting mainly of gum and amounting to 28 per cent. of the dry drug; the filtrate was freed from alcohol by evaporation, fermented with yeast, and, after the sugar had been thus destroyed, yielded with acetate of lead a slight precipitate. After removing the lead from the filtrate by sulphuretted hydrogen the resulting extract had a bitter and acrid taste, the latter of which was removed by agitation with hydrate of lead, but not by baryta. The earlier investigations were less successful. Vogel's and Tilloy's *scillitin* was amorphous and neutral; both regarded the acrid principle as being volatile. Landerer and Marais (1857) obtained compounds which they regarded as alkaloids. But Tilloy (1854) proved the non-existence of such a body in squill, and announced then that squill does not contain any volatile acrid principle; the compound producing irritation of the skin was by him believed to be crystallized citrate of calcium. Labourdais (1849) obtained the bitter principle, after precipitating the infusion of squill with acetate of lead, by treating it with animal charcoal, and exhausting this with hot alcohol; and Bley obtained it once by this process in flexible needles. The presence of crystals in squill was recognized long ago, but these were generally considered to be either tartrate, carbonate, or citrate of calcium, until Schroff (1864) proved them to be very fine and sharp-pointed needles of *oxalate of calcium*. Schroff is likewise convinced of the existence of a non-volatile acrid besides the bitter principle, and of the greater efficacy of the red-colored variety of the drug. The bitter principle forms a compound with tannic acid (*Pharmacographia*). Jarnersted (1879) isolated from this precipitate the glucoside *scillein*, which is white or yellowish, dissolves in strong hydrochloric acid with a red color, and is decomposed by dilute acids into glucose and a resin. E. Merck (1879) obtained three not quite pure principles, the two last of which are poisonous—namely, *scillin* (crystalline, pale-yellow, sparingly soluble in water, more freely soluble in alcohol and hot ether, colored by sulphuric acid red-brown, by nitric acid yellow, and on heating green); *scillipicin* (amorphous, whitish, hygroscopic, and bitter); and *scillitoxin* (amorphous, cinnamon-brown, insoluble in water and ether, soluble in alcohol, colored red and brown by sulphuric acid and orange-red

FIG. 263.

*Scilla maritima*, Linné.

and green by nitric acid). Schmiedeberg (1879) isolated the gummy matter by precipitating the infusion with basic lead acetate, and afterward with lime; on decomposing the last precipitate with carbonic and oxalic acids *sinistrin*, $C_6H_{10}O_5$, is obtained: this is colorless, amorphous, levogyrate, and is readily converted into levulose and another fermentable but inactive sugar. *Scillin* of Riche and Rémont (1880) is probably identical with *sinistrin*.

Off. Prep.—Acetum scillæ, *U. S.*, *Br.*; Extract. scillæ fluid., *U. S.*; Oxy-mel scillæ, *Pil. ipecacuanhæ cum scilla*, *Pil. scillæ comp.*, *Br.*; Syr. scillæ, *U. S.*, *Br.*; Syr. scillæ comp., *U. S.*; Tinct. scillæ, *U. S.*, *Br.*

History.—Squill was used by the Greeks and their medical followers in Rome, Arabia, and Europe. Its preparations with honey and vinegar were anciently employed in dropsical affections, and the latter were extolled in the treatment of spongy and ulcerated gums, ulcerated throat, and debility of the digestive organs.

Physiological Action.—*On Animals:* Squill acts poisonously upon various animals. The camel is said to reject it from among the plants on which he browses. It is fatal to mice, rabbits, cats, dogs, swine, fowls, etc. In most of these animals it appears to occasion pain with vomiting, great distress and purging, and loss of muscular power or convulsions. When administered to dogs the animals grow dull, slaver, and seem nauseated; vomiting and liquid stools follow. If the dose be large, trembling succeeds, and paralysis of the hind and then of the anterior limbs. Convulsions ensue with general muscular resolution immediately before death. 4 grains of scillitin have destroyed a dog of medium size within 24 hours. In rabbits the alcoholic extract of squill, and also scillitin, occasion contraction of the pupils, great debility, sinking of the pulse, diuresis, dyspnoea, and death. After death by scillitin inflammation and erosion of the stomach and hæmorrhagic transudations about the heart and lungs and in the kidneys and brain are found. Later experiments appear to show that in animals (cats, rabbits, pigeons, frogs) the extract of squill renders the pulse less frequent, and causes death by arresting the heart in systole before respiration is suspended; to this action, which, at least in its primary stage, implies an augmented arterial blood-pressure, the diuretic operation of the medicine is attributed. In these experiments the extract of squill (contrary to earlier observations) does not appear to have produced any lesion of the stomach nor any inflammation of the kidneys or bladder, but the lungs, and sometimes the pleuræ, were congested as an effect of the impeded circulation through the heart. No depression of the animal temperature was observed (Husemann and König). Still more recently, the experiments of Jarmersted (*Archiv f. Pathol. u. Pharm.*, xi. 22), Drouot (*Amer. Jour. Med. Sci.*, July, 1879, p. 243), Merck (*Med. Record*, xvi. 325), Lipinskii (*Bull. de thérap.*, ci. 465), and others have rendered it evident that there is in squill a constituent whose action closely resembles that of digitalin, and which has been variously called scillain, scillipierin, and scillitoxin. Jarmersted found that in cats and dogs it caused vomiting and purging, became fatal through a tonic contraction of the heart: first increased, and then lowered, the blood-pressure, with the former slowing, and with the latter accelerating, the pulse.

On Man: The juice of the fresh plant acts upon the skin as a rubefacient, and has also occasioned diuresis. Even the powder of the dried corm applied to the denuded cutis has had the same effect in dropsy. Its local action is irritating, which is ascribed to the large proportion it contains of oxalate of lime. Internally, the effects of a very large dose of squill are violent vomiting, purging, and colic, dysury or bloody urine, rapid breathing, a cold skin, coma, and general convulsions. It has even destroyed life. In small or medicinal doses it usually exerts a diuretic action, tends to relax the bowels, and reduces the frequency and increases the tension of the pulse. The characteristic effects are most distinctly produced by the powder or the wine of squill. The syrups of squill in medicinal doses and in disease appear to act rather upon the bronchial mucous membrane. The continued use of squill impairs the appetite and digestion.

Medical Uses.—Although there is nothing in the results of scientific investigation even to suggest that squill acts upon the bronchial mucous membrane, the much more direct and conclusive evidence of clinical experience leaves no doubt of its great value in *bronchitis*, whether of an acute form, when the sputa are tenacious and scanty, or of a chronic type occurring without complication or associated with obstructive disease of the heart and pulmonary emphysema. It is of daily use as an expectorant in the treatment of *spasmodic croup*, but in the form of compound syrup of squill, which owes its efficacy chiefly to the antimony it contains.

As a diuretic squill is universally employed in *dropsy*. Even when the effusion is owing to some organic and incurable lesion, it may often be temporarily evacuated by squill. The

experimental researches into its mode of action in dropsy have tended to confirm what was long ago established by clinical experience, that it is most useful in the passive forms of the disease, when the pulse is weak and the heart feeble or obstructed, and when there is neither fever nor an irritable condition of the kidneys present. Undoubtedly, it is oftener useful in cardiac than in renal, splenic, or hepatic dropsy. As already mentioned, it seems probable that its action is very analogous to that of digitalis. Within certain limits this is true, but is not the whole truth. The diuretic action of neither medicine is due exclusively to its sensible sedative action on the heart. Squill is not so apt as digitalis to cause sudden and alarming depression. The best mode of using these medicines in dropsy is to combine them in the same prescription in pilular form, or as tinctures with compound spirit of juniper, or with a solution of acetate of potassium in water. When the stomach is intolerant of the medicine, it may be administered by rubbing its tincture with that of digitalis into the skin, or applying compresses saturated with these liquids to the abdomen and covering them with impermeable cloth. Scillipierin dissolved in water may be administered hypodermically. It is apt, however, to cause some local irritation. In one case 4 tablespoonfuls a day of a 2 per cent. solution of scillipierin were given without effect. For subcutaneous injection a 10 per cent. solution has been preferred (Fronmüller). Powdered squill, with or without digitalis, may also be applied endermically. In the *hydrocele* of young subjects a cure has been effected by applications of vinegar of squill. Powdered squill has been used to remove warts.

The dose of squill in substance is from 1 to 3 grains (Gm. 0.06–0.20), three times a day in pilular form. It may gradually be increased to 10 grains a day. As a general rule, if it disturbs the stomach the dose should be reduced. An infusion is sometimes employed, which is made with from half a drachm to a drachm of squill in half a pint (Gm. 2–4 in Gm. 250) of hot water, of which from 2 to 4 fluidrachms (Gm. 8–16) may be given at a dose.

SCOPARIUS, U. S.—SCOPARIUS.

Scoparii cacumina, Br.; *Herba scoparii*.—Broom, Irish broom, E.; *Genêt à balais*, Fr.; *Besenginster*, *Pfriemenkraut*, G.

The tops of *Sarothamnus* (*Cytisus*, Link) *scoparius*, Koch, *Sar. vulgaris*, Wimmer, *Genista scoparia*, Lamarek, *Spartium scoparium*, Linuë. Bentley and Trimen, *Med. Plants*, 70.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Origin.—Broom is a shrub about 3 to 6 feet (.9–1.8 M.) high, and grows in Western Siberia and throughout the greater portion of Europe, but is more abundant in the western part of that continent and in Great Britain. It is sometimes cultivated in our gardens, and is occasionally met with wild in some of the Middle and Southern States. It prefers a sandy soil, and flowers in May and June. The shrub has long, wand-like branches, small trifoliate leaves with obovate or elliptic-lanceolate sessile leaflets and produces an abundance of large golden-yellow papilionaceous flowers, and a flat dark-brown legume, which is white-hairy on the edges, and contains about twelve olive-colored, oblong, and, below, truncate seeds. The flower-buds are in some places used like capers, and the branches as a substitute for hops.

Description.—The green twigs constitute the portion generally employed. They are long, thin, and flexible, pentangular, winged, but not spiny, smooth, except the extremities, which are pubescent, and are usually free from leaves and flowers. In the fresh state they have a peculiar odor, but are nearly inodorous after drying; their taste is bitter and disagreeable. The flowers have been occasionally employed; on drying they usually become brown and their honey-like odor is almost entirely lost; their taste is nauseous and bitter.

Constituents.—The analyses by Cadet de Gassicourt (1824) and Reinsch (1846) failed to isolate any important principle. Stenhouse (1851) obtained two interesting principles, scoparin and sparteine. *Scoparin*, $C_{21}H_{22}O_{10}$, is prepared from the concentrated decoction of broom-tops, which gelatinizes on standing; the jelly-like mass is expressed and purified by repeated solution in hot water, and finally in hot alcohol. Scoparin is amorphous and brittle or in small crystals, has a pale-yellow color, yields with lead acetates green-yellow precipitates, and furnishes picric acid when treated with nitric acid; it is inodorous and tasteless. On fusing it with potassa, phloroglucin and protocatechuic acid are produced (Hlasiwetz). *Sparteine*, $C_{15}H_{26}N_2$, is best obtained, according to Mills (1861), by exhausting broom with acidulated water and distilling the concentrated liquid with

soda. In its pure state it is a colorless, transparent, oily liquid, which becomes brown on exposure, has a slight aniline-like odor, a very bitter taste, a strongly alkaline reaction, boils at 288° C. (550° F.), and yields amorphous and crystallizable salts. The alkaloid is but slightly soluble in water and alcohol. 150 pounds of the plant yielded 22 Ccm. of sparteine. The air-dry plant yields about 5.6 per cent. of ash.

Off. Prep.—Decoct. scoparii, Succus scoparii, *Br.*

Allied Species.—*SPARTIUM JUNCEUM*, *Linné* (*Spartianthus*, *Link.*, *Genista*, *Lamarck*). Spanish broom. This evergreen European shrub resembles the preceding, but has obtuse-lanceolate, at the base wedge-shaped, and on the lower side soft-hairy leaves, and nearly reniform seeds. The branches, leaves, and seeds have a bitter taste, and are stated to possess diuretic, purgative, and emetic properties.

History.—Broom had long been known and used by the people as a remedy for dropsy, and its virtues had been celebrated by Floyer and by Culpepper in the seventeenth century, before Mead and Cullen introduced it into medical practice. Even the shepherds were accustomed to cure their dropsical sheep by feeding them with the fresh plant. A German clergyman first published an account of its virtues in eczema and other cutaneous diseases.

Medical Action and Uses.—No other medicine is entitled to more credit than broom for removing *dropsical effusions*. Its diuretic virtues depend in part upon the potassium salts that exist in it, and in part also upon its proximate principle, sparteine. The latter is a sedative of the spinal reflex centres, and in a less degree of the circulatory system, and it even acts upon some of the lower animals in a slight degree as a narcotic (Fick). A drop of sparteine introduced by Schroff into a rabbit's mouth occasioned spasms of the muscles of the spine and limbs and paralysis of the latter, slowing of the respiration and heart, and death in 6 minutes. On dissection the intestine responded but feebly to stimulation, the heart, except the auricles, not at all, and the venous system was gorged with blood. The phenomena noted by Fick were somnolence, a staggering gait, at first extreme frequency of the pulse and respiration, and subsequently great dyspnoea and slowing and feebleness of the heart, and finally death in convulsion, with dilated pupils. Its effects have caused it to be compared with conine, but they do not in the least degree explain the value of broom as a diuretic medicine.

Broom is applicable to all forms of *chronic dropsy* as one of the most efficient of hydragogues, acting both by the bowels and the kidneys. It is best given in a decoction prepared by boiling half an ounce (Gm. 16) of the tops in half a pint (Gm. 250) of water in a covered vessel for 10 minutes. This quantity may be taken in divided doses in 24 hours, or the official decoction (*British Pharmacopœia*) may be used instead. A compound decoction, which is still more efficient, may be prepared by boiling broom tops and dandelion, of each $\frac{1}{2}$ ounce (Gm. 16), in $1\frac{1}{2}$ pints of water to a pint (Gm. 750 to Gm. 500), and near the close of the process adding $\frac{1}{2}$ ounce (Gm. 16) of juniper-berries. When cold, the decoction should be strained. 1 or 2 fluidounces (Gm. 36–64) may be given at a dose. *Scoparin* and *sparteine*, dissolved in water with the aid of glycerin, have been successfully used subcutaneously to produce diuresis.

SCROPHULARIA.—FIGWORT.

Scrofula-plant, E.; *Scrofulaire*, Fr.; *Kropfwurz*, *Knotenwurz*, G.

Scrophularia nodosa, *Linné*.

Nat. Ord.—Scrophulariaceæ.

Origin and Description.—Figwort is a perennial herb growing in damp places in Europe and North America. The American plant is usually taller, growing to the height of 4 or 5 feet (1.2–1.5 M.), and has an obtusely angled stem, but otherwise agrees closely with the European plant; it was formerly regarded as a distinct species, *Scrophularia marilandica*, *Linné*. The plant has a horizontal branching fleshy *rhizome*, to which numerous oblong or oval tubers of the thickness of a thumb are attached. The *leaves* are opposite, petiolate, ovate-oblong, rounded or heart-shaped at the base, and cut-serrate on the margin. The flowers are in a terminal loose panicle, have a greenish-brown, tubular-globose, five-lobed corolla with four stamens, and produce a two-celled many-seeded capsule. The fresh plant, bruised, has an unpleasant odor and a nauseous, bitter, and acrid taste; on drying it loses about 75 per cent. in weight and becomes nearly inodorous.

Constituents.—The fresh flowering plant was analyzed by Walz (1853), who found in the aqueous distillate *acetic* and *propionic acids* and a stearopten, *scrophularosmin*. On treating the decoction with acetate and subacetate of lead, tannic, tartaric, citric, and malic acids, pectin, and coloring matter were precipitated, and the filtrate, after freeing it from lead, yielded with tannin a precipitate containing *scrophularin*. This principle crystallizes in scales, has a bitter taste, and is soluble in water and alcohol. *Scrophularia aquatica*, *Linné*, contains the same principle, and in addition thereto a resinous body, *scrophulacrin*, which is soluble in ether.

Medical Action and Uses.—*S. nodosa* and *S. aquatica* appear to possess analogous qualities. The generic name of the plant seems to have been gained through a popular belief that it was useful in *scrofula*. It was employed in the glandular form of the disease, and also in *cutaneous affections* originating in the strumous diathesis. It was an ingredient of an ointment much used in the treatment of *itch*. It was also applied to *hemorrhoids* and *anal ulcers* and as a dressing for unhealthy *wounds* and *sores* generally. The fresh juice, and also a decoction of the leaves or root, were used, the latter being made with half an ounce to a pint of water (Gm. 16 to Gm. 500).

SCUTELLARIA, U. S.—SKULLCAP.

Hoodwort, *Madweed*, E.; *Scutellaire*, Fr.; *Helmkraut*, *Schildkraut*, G.

Scutellaria lateriflora, *Linné*.

Nat. Ord.—Labiatae, Stachydeæ.

Description.—This species, in some places known as *mad-dog skullcap*, is a common North American perennial herb, growing in swampy and wet places. Its stem is about 2 feet (60 Cm.) high, quadrangular, smooth, and much-branched. The leaves are opposite, petiolate, about 2 inches (5 Cm.) long, oval-lanceolate, pointed, coarsely serrate, rounded at the base, thin, and smooth. The flowers are small, in slender axillary leafy racemes, with a minute filiform bract at the base of each pedicel, and with a pale-blue or purplish bilabiate corolla. The calyx is divided into two entire lips, the upper with a helmet-like appendage on the back. The herb flowers in July, and should then be collected; its loss, on drying, amounts to from 75 to 80 per cent. It has a slight odor and bitterish taste. Its constituents have not been ascertained.

Allied Species.—The following and probably other indigenous species of *Scutellaria* possess a more decidedly bitter taste, and are occasionally employed:

SCUT. INTEGRIFOLIA, Linné. It is 12 to 18 inches (30 to 45 Cm.) high, minutely hairy all over, has lance-oblong or linear-oblong, mostly entire, short petiolate leaves, and terminal racemes of blue flowers, which are about an inch (25 Mm.) long.

SCUT. PILOSA, Linné. It is 1 or 2 feet (30 to 60 Cm.) high, covered with spreading hairs, has rhombic- or oblong-ovate, crenate, petiolate leaves in distant pairs, and short terminal racemes of rather large purplish-blue flowers.

SCUT. GALERICULATA, Linné. It is somewhat downy, has short-stalked, lance-ovate, crenately serrate leaves, which are rounded or heart-shaped at the base, and bear in the axils of the upper leaves rather large blue flowers, which are turned to one side. This species is indigenous to Europe, Northern Asia, and the northern section of North America.

BRUNELLA (PRUNELLA) VULGARIS, Linné.—Heal-all, Self-heal, E.; Pâquerette, Fr.; Braunelle, Braunheil, G.—This is a perennial herb, common in fields, grassy places, and in woods in North America, Asia, and Europe. Its ascending stem is about 12 inches (30 Cm.) long; the leaves are about 1½ inches (38 Mm.) long, petiolate, oblong-ovate, entire or somewhat toothed, and more or less hairy. The flowers are purplish-blue and form a dense leafy-bracted spike. The herb is nearly inodorous, and has a bitterish and somewhat astringent taste.

Constituents.—These plants contain principles similar to those found in other plants of the same order. Cadet de Gassicourt (1824) obtained from the officinal species a little volatile oil, fat, tannin, a trace of bitter principle, sugar, etc.

Medical Action and Uses.—Skullcap has been employed in extract, fluid extract, and infusion, and has had some repute in *intermittent fever* and as a nervine—that is, in diseases presenting a depressed and disordered condition of the nervous functions. It has even been recommended in *epilepsy* when continuously given in a decoction made with 2 ounces of the herb to 8 ounces of water (Gm. 64 to Gm. 250). There is no evidence of its virtues which entitles it to a place among officinal drugs.

SEDUM.—STONECROP.

Mossy stonecrop, E.; *Joubarbe âcre*, *Poire des murailles*, Fr.; *Mauerpfaffier*, *Steinkraut*, G.

Sedum acre, Linné.

Nat. Ord.—Crassulaceæ.

Description.—This little moss-like spreading plant is indigenous to Europe, where it grows in dry fields and on old walls; it is cultivated in gardens and runs wild in some places in North America. Its leaves are $\frac{1}{2}$ to $\frac{1}{4}$ inch (3–6 Mm.) long, alternate, nearly imbricate, in about six spirally turned rows, ovate, thick, convex on the back, punctate, and smooth. The flowers are on one side of the branched inflorescence, forming scorpioid cymes, and have four or five yellow petals, the same number of pistils, and twice that number of stamens. The plant is inodorous and has a mucilaginous and acrid taste.

Constituents.—Mossy stonecrop contains much mucilage and malates (Vauquelin), also rutin (Mylius); its acrid principle has not been isolated.

Allied Species.—*SEDUM TELEPHIUM*, Linné.—Live-for-ever, Garden opine, E.; *Joubarbe des vignes*, Grassetto, Fr.; *Grosse Fetthenne*, G.—It is likewise indigenous to Europe, and in the United States has escaped from cultivation. It has a spindle-shaped root, an ascending stem about 20 inches (50 Cm.) high, and oval or ovate, obtuse and toothed sessile leaves, which are 2 or 3 inches (5–8 Cm.) long, and are either alternate, opposite, or in whorls of three. The purplish or greenish flowers are in dense compound cymes.

SEMPERVIVUM TECTORUM, Linné.—Houseleek, E.; *Grande joubarbe*, Fr.; *Hauswurz*, *Dachwurz*, G.—It is indigenous to the Alps, but now grows spontaneously throughout Europe on roofs and old walls, and, with several allied species, is cultivated in North America. It has numerous fleshy rosulate radical leaves, which are 1 to 2 inches (2–5 Cm.) long, obovate in shape, of a green color, and on the margin stiff-hairy, and often of a brownish or reddish color. The flowers are rose-colored and purplish. The leaves have an acidulous taste and contain malates.

PENTHOTHUM SEDOIDES, Linné (Ditch-stonecrop), is not fleshy, has a stem about 16 inches (40 Cm.) high, lanceolate serrate leaves, and terminal spike-like secund racemes of greenish or yellowish flowers having a five-beaked ovary. The plant is common in wet places in North America, and is used in nasal catarrh.

Medical Action and Uses.—Experiments upon animals appear to show that stonecrop is an active local irritant and also a depressor of the nervous system. In man the expressed juice, in large doses, acts as an acrid emetic and purgative, and is capable of blistering the skin. *Sedum* was formerly in common use as a remedy for *scorfula*, and was administered internally in decoction and applied to the ulcerated skin, etc. Its emeto-cathartic action was employed in the treatment of *intermittent fever*, and also in *dropsy* and *epilepsy*, with a certain degree of success, but the plant appears to have been found more really useful when it was applied bruised or its expressed juice was used as an application to scrofulous, cancerous, and other *ulcers*, as a resolvent to enlarged lymphatic glands, and as a dressing for chronic diseases of the skin. The juice has also been used to remove *warts* and *corns*. The dried plant was prescribed internally in powder in the dose of 12 or 15 grains (Gm. 0.8–1), or a decoction was made with a handful of it in a pint of beer. The juice was given in doses of 2 or 3 fluidrachms (Gm. 8–12), or, as others state, of from 8 to 30 grains (Gm. 0.5–2), in wine. Externally, the bruised fresh plant was generally preferred.

Houseleek has been described as refrigerant, astringent, anti-spasmodic, and detergent. Its expressed juice was once prized in *dysentery* and in *hysterical disorders*, and externally as a dressing for *ulcers* and chronic skin diseases, *hemorrhoids*, etc. It is still used to soften *corns* and *warts*.

SELINUM.—MARSH-PARSLEY.

Radix olsnitii.—*Sélin* (*Persil*) *des marais*, Fr.; *Sumpfsilge*, *Elsenich*, G.

The root of *Selinum* (*Thysselinum*, Hoffmann, *Peucedanum*, Moench) *palustre*, Linné. Nat. Ord.—Umbelliferae, Orthospermæ.

Origin.—This is a perennial plant indigenous to Europe, and growing in swampy and moist localities. It is about 4 feet (1.2 M.) high, has twice or thrice pinnately divided and cleft leaves with linear-lanceolate lobes, large and lax compound umbels of white flowers, and oval-oblong brown fruits.

Description.—The root is about 6 inches (15 Cm.) long, in the upper part nearly 1 inch (25 Mm.) thick, one- or several-headed, annulate above, with deep longitudinal wrinkles, grayish-brown, and with scattered whitish suberous warts. The bark is thick,

spongy, and brown, and contains a circle of rather large laticiferous vessels; the medullium is soft and often radially cleft. The root has a strong, disagreeable, somewhat terebinthinate odor and a pungent and acrid taste.

Constituents.—The chemical constituents are analogous to those of other umbelliferous roots—volatile oil, mucilage, sugar, etc. Peschier's *selinic acid* has not been further investigated.

Allied Plants. See (HERACLEUM, p. 763), IMPERATORIA (p. 812), and LEVISTICUM (p. 879).

Medical Action and Uses.—The juice of this plant is said to be irritating, and even caustic, in its action. Many years ago it was found to be a popular remedy for *epilepsy* in the Russian province of Courland. It afterward attracted a good deal of attention in Paris, and received for a time greater credit than it deserved. It was exhibited in powder in the *dose* of from 30 to 40 grains (Gm. 2–4), several times a day. This medicine is no longer employed in epilepsy.

SENECIO.—GROUNDSEL.

Senecion, Fr.; Kreuzkraut, Jacobskraut, G.

Nat. Ord.—Compositæ, Senecionideæ.

Description.—Several European species of this genus have been employed, among which may be mentioned *Sen. saracenicus*, *S. Dorianum*, *S. Jacobæ*, and *S. vulgaris*, *Linneé*. The latter, with rayless flower-heads, is a common weed in Europe and sparingly naturalized in North America. It has lanceolate, pinnatifid, and toothed, clasping and rather fleshy leaves, and a cylindrical involucre; it is inodorous and has a bitterish saline and acrid taste. The most common North American species is *Senecio aureus*, *Linneé*, known as *golden rag-weed*, *squaw-weed*, and *life-root*. It is found on the borders of streams, in thickets, and in swamps, and has a thin horizontal rhizome with numerous slender rootlets; long-petioled, round or roundish heart-shaped, and crenately toothed radical leaves; lyrate or pinnatifid, usually lanceolate stem-leaves; and a corymbose inflorescence with many-flowered heads, having bright-yellow pistillate ray-florets. There are many varieties, differing chiefly in the shape of the radical leaves. These plants seem to contain a little tannin and a bitter and an acrid principle.

Medical Action and Uses.—Groundsel appears to be emollient and also slightly acrid. It was employed by the American aborigines as a vulnerary. In Germany its juice is a domestic remedy for *colic*, *intestinal worms*, etc. It is used in France to prepare gargles for *sore throats*, to make poultices for *boils*, *rheumatic swellings*, and local *cutaneous eruptions*, and to prepare emollient and laxative enemata. Dr. N. S. Davis found that in doses of from 45 to 90 minims (Gm. 3–6) the fluid extract of senecio-root relieved the pains of chronic muscular *rheumatism* (*Phila. Med. Times*, ix. 634). A decoction may be prepared with 1 or 2 drachms in 4 ounces of water (Gm. 4–8 in Gm. 120).

SENEGA, U. S.—SENEGA.

Senegæ radix, Br.; *Radix senegæ*, P. G.—*Seneka-root*, *Senega snakeroot*, E.; *Polygale de Virginie*, Fr.; *Senegawurzel*, G.

The root of *Polygala Senega*, *Linneé*.

Nat. Ord.—Polygalacææ.

Origin.—Senega is a native of North America from Canada southward to South Carolina and westward to Wisconsin. It has numerous slender stems about a foot (30 Cm.) high from each root. The leaves are alternate, sessile, lanceolate or oblong-lanceolate, rough on the margin, otherwise smooth, and narrowed to both ends. The flowers are nearly sessile, in slender terminal spikes, and have five sepals, of which the two lateral ones are round, petaloid, and rose-colored; the three petals are whitish. Senega flowers in May and June, and ripens its small two-celled and two-seeded capsule in July. The root is collected in autumn, mainly in the Southern and Western States.

Description.—Senega-root has a head or crown which is $\frac{1}{2}$ or 1 inch (12–25 Mm.) in diameter, very knotty from the numerous thin remnants of stems, and is below contracted into the root, having a diameter of $\frac{1}{8}$ or $\frac{1}{4}$ inch (4–6 Mm.). The root is 4 or 6 inches (10–15 Cm.) long, and divided into several branches nearly uniform in thickness, which are tapering below, usually spreading, more or less tortuous, fleshy and cylindrical when fresh, but after drying twisted and furnished with a projecting ridge or keel, which

runs around the root in about one spiral turn from near the base to the tip. Opposite the keel are sometimes seen irregular annulations; otherwise the root is longitudinally wrinkled. Externally, it varies in color between yellowish-gray and brownish-yellow, and is whitish internally. When cut transversely it presents a porous, yellowish radially striate ligneous portion and a thick white bark. The wood is circular near the crown, and surrounded by bark nearly uniform in

FIG. 264.

Senega-root: section showing one-sided growth of wood and inner bark, magnified 18 diameters.

FIG. 265.

Transverse sections of Senega-root.

thickness. At some distance from the head the wood presents a more or less irregular appearance, being rounded on one side and only partially developed on the opposite side. The bark is seen to consist of two layers, the inner one of which is found chiefly on the rounded side of the wood, and projects more or less conically into the keel, which is therefore formed by the one-sided development of the inner bark. On soaking the root in water the outer bark swells to a greater extent than the inner layer, and the root becomes again nearly cylindrical. Senega-root has a slight odor when dry, but the liquid preparations of it have a characteristic, rather nauseous odor; the taste is sweetish, and afterward persistently acrid. The root is brittle and breaks with a short fracture.

Senega-root of the above description is collected in Virginia and westward to Arkansas and Missouri, and is sometimes designated as "Southern senega." Since about 1870 senega of much larger dimensions has frequently been seen in the market; the head is often 2 or 3 inches (5-8 Cm.), and the top portion of the root sometimes $\frac{1}{2}$ inch (2 Cm.), thick; the root is less contorted, more fleshy, and the branches show the keel often rather indistinctly. Prof. Lloyd (1881) has shown that this "Northern senega" is derived from a variety of *Polygala senega* growing in Minnesota and Wisconsin; from the latter State we have also roots agreeing in every respect with Southern senega.

Constituents.—The acrid taste of senega-root is due to *senegin* (Gehlen, 1804), *polygalin*, or *polygalic acid* (Peschier, 1821). Quevenne (1836) prepared it in a nearly pure condition, and Procter (1859) obtained 5½ per cent. of it by exhausting the root with 60 per cent. alcohol, concentrating the tincture to about one-half the weight of the root, removing coloring matter by means of ether, and mixing the syrupy liquid with strong alcohol and ether, which precipitates the polygalic acid as a light fawn-colored powder, requiring to be washed with a mixture of ether and alcohol; the mother-liquor, from which Procter obtained a small quantity of crystals, seems to contain the salt of an organic acid. Precipitation with baryta gave to Christophsohn a yield of 2½ per cent. of white amorphous senegin. *Polygalin* of Peschier is volatile, and is contained in the aqueous distillate of the root, therefore identical with the trace of volatile oil observed by Dulong (1827). Bucholz, and afterward Bolley (1854), regarded senegin as identical with *saponin*; and this view seems to be sustained by the observations of Christophsohn (1874) and Schneider (1875). But Quevenne obtained from an aqueous solution of senegin only a slight precipitate with acetate of lead, which disappeared on the addition of more of the reagent; while Roehleder and Schwarz state that saponin yields with the same salt a gelatinous precipitate, which, according to Bucholz, is soluble in acetic acid. According to Braconnot and Bussy, saponin is not precipitated by acetate of lead. On the other hand, polygalic acid, like saponin, is precipitated from its aqueous solution by baryta; the products of decomposition of the two bodies by acids appear to be identical; and the gelatinous mass observed by Quevenne to be produced from his polygalic acid with cold concentrated hydrochloric acid and with boiling dilute mineral acids appears to be *sapogenin*. Evidently further investigations are required to determine the chemical relations of these bodies. According to Trommsdorff (1832) and Schneider, the activity of senega resides chiefly in the cortical portion; however, the wood of the large senega described above is quite acrid, though less so than the bark.

Liquid preparations of senega are apt to become gelatinous, which property is usually ascribed to the presence of pectin compounds, but is very likely, at least in part, due to *sapogenin*, generated under the influence of acids or of other compounds; the jelly is rendered soluble again on the addition of an alkali. Flückiger (*Pharmakognosie*, 2d edit.) obtained from powdered senega by ether 8.68 per cent. of fixed oil containing free acids, and, after saponification and acidulation of the lye, yielding a distillate having the odor of acetic and valerianic acids. The *virginic acid* of Quevenne and the bitter principle *isolusin* of Peschier have not been investigated. Other less important constituents of senega are a little resin, 7 per cent. of sugar, malic acid, etc.

Off. Prep.—Abstractum senegæ, Extr. senegæ fluid., U. S.; Infusum senegæ, Br.; Syrup. scillæ comp., Syr. senegæ, U. S.; Tinct. senegæ, Br.

Allied Roots and Substitutions.—*POLYGALA BOYKINII*, Nuttall, a plant growing in the Southern and South-western States of North America, has a root which has been used by Dr. J. H. Gunn (1881) in place of senega, and which has the same appearance as rather small specimens of the latter, but is destitute of the keel, and has a cylindrical wood and a thinner uniform bark. We believe this to be identical with the *white* or *false senega* which was quite common in the market for several years after 1875, but appears to be no longer met with at the present time. It was said to have been collected in South-western Missouri. This root yielded to Geo. Goebel (1881), by Quevenne's process, 3 per cent. of senegin, and all preparations made with it were much lighter in color than the corresponding preparations of true senega.

FIG. 266.

False Senega: transverse section, magnified 10 diameters.

Another kind of so-called white senega which we have seen was amylaceous internally, and had none of the prominent characteristics of the pharmacopœial drug.

Ginseng-root and the rhizome of *Cypripedium* are sometimes found among commercial senega as accidental impurities: they do not resemble senega-root, and are easily distinguished from it. The same may also be said of the roots of *Ionidium Ipecacuanha* (p. 839), *Cynanchum Vincetoxicum* (p. 537), and of valerian, which have occasionally been mentioned in Europe as adulterations of senega.

Physiological Action.—The following symptoms were caused by taking 20 grains of senega three times within 6 hours: An unpleasant irritation of the fauces and throat, with copious salivation, was succeeded by heat at the epigastrium and violent mucous vomiting; the skin meanwhile grew moister and warmer, and sharp colic with watery diarrhœa followed; the urine was increased, and scalded when voided. In larger doses senega excites severe burning pain in the stomach, violent vomiting, purging, anxiety, and giddiness.

The action of *sapogenin* has been more closely studied. When a bottle containing it is applied to the nostrils it excites sneezing and a bronchial and post-sternal irritation, which may last for an hour. A strong solution of it applied to the skin of a frog's thigh or a rabbit's shaven skin occasions redness, due to a thorough capillary congestion, with anæsthesia of the part. The red corpuscles thus aggregated appear to wilt and lose their shape and color.

When a strong solution of saponin is injected into a frog's thigh, it impairs the motility and sensibility of the limb and abolishes the reflex excitability of the muscles. The muscular flaccidity may ultimately be succeeded by tonic rigidity. These facts occur even when the limb is partially or wholly severed from the body of the animal, and are therefore independent of the great nervous centres. If the poison is directly applied to the heart through the circulation or otherwise, it reduces the frequency and force of the contractions of the organ, and finally paralyzes it. The local effects of its application elsewhere are the first to appear, but gradually the heart and nervous centres become involved. These phenomena have been described in the current pharmaco-dynamical language of the day as follows: "Saponin, introduced into the blood, paralyzes the muscles and the nerves, and in a peculiar manner the nerves of the heart, since it paralyzes as well the terminations of the vagus and inhibitory centres, and the accelerator nerves derived from the sympathetic, and finally arrests the movements of the heart. . . . Saponin also acts speedily upon the vaso-motor centre, paralyzing it, slowly or rapidly according as the dose is small or large."

Keppler injected $1\frac{1}{2}$ grains of saponin into the inner side of his thigh. Severe pain and local inflammation ensued, although the part immediately around the puncture was anaesthetic. The temperature rose for 3 hours, but in 24 hours it fell to the normal point, and on the fifth day to 93° F. This prolongation of its action showed the slight diffusibility of the drug. Among the general symptoms were mental depression, somnolence, salivation, pallor, cold sweats, a tendency to syncope, chattering of the teeth, nausea, photophobia, exophthalmos, and strabismus (Husenmann, etc., *Die Pflanzenstoffe*, 2te Aufl. p. 536). But neither in these experiments nor in those of Eulenberg was there any indication of that muscular anaesthesia ascribed to saponin by Pelikan and others.

Medical Uses.—Physiological investigation of the action of senega and saponin has shed no light upon their clinical applications. They are practically useless as anaesthetics and cardiac sedatives. Nor does their mode of action help to explain the recognized utility of senega in the different forms of bronchial and pulmonary disorder in which it has been found advantageous. These are, first, *typhoid pneumonia*, in which, *a priori*, a stimulant and not a sedative remedy is indicated, yet it is precisely in that affection, and not in the inflammatory form of pneumonia, that senega has won its reputation, and especially in the decline of the disease, when it would seem that a stimulant expectorant is called for. In like manner senega is useful in *bronchorrhoea* and in chronic *bronchitis* with profuse expectoration. Even in *croup* (spasmodic laryngitis) it is most appropriate after the inflammatory stage with spasm has passed and the affection has become a simple catarrhal laryngitis. In like manner, when it was prescribed in the treatment of *amniorrhoea*, the cases in which it seems to have done good were those of passive and not of active congestion of the uterine system. The diuretic operation of senega is too inconsiderable to constitute it a trustworthy remedy in any form of dropsy.

The *dose* of powdered senega is from 10 to 20 grains (Gm. 0.60–1.30). The abstract and fluid extract are officinal.

SENNA, U. S.—SENNA.

Folia semar, P. G.; *Senna alexandrina* and *S. indica*, Br.—*Senna-leaves*, E.; *Feuilles de séné*, Fr.; *Sennesblätter*, G.

The leaves of *Cassia acutifolia*, *Delile* (of *C. obovata*, *Colladon*), and of *C. elongata*, *Lénaire-Lisancourt*. Bentley and Trimen, *Med. Plants*, 89, 90, 91.

Nat. Ord.—Leguminosæ, Cæsalpineæ.

Origin.—The subgenus *Senna* of the genus *Cassia* is regarded by some botanists as a distinct genus, characterized by the absence of glands from the common petiole of the leaves, by the axillary racemose inflorescence, and by the flat, broad, papyraceous legumes, which are indehiscent, cleft on the margin at maturity, and contain near the middle the small triangular or truncately wedge-shaped seeds attached to a long funiculus. The senna-yielding species are small shrubs 2 or 3 feet (60–90 Cm.) high, have small, persistent stipules and axillary racemes of yellow flowers.

CASSIA ACUTIFOLIA, *Delile* (*C. lanceolata*, *Nectoux*; *C. Senna* β , *Linneé*; *C. orientalis*, *Persoon*; *C. lenitiva*, *Bischoff*; *Senna acutifolia*, *Batka*). It is found in Upper Egypt and southward to Nubia, Sennaar, and Kordofan, and farther westward in tropical Africa. The leaflets are mostly in four or five pairs, are from $\frac{1}{2}$ to $1\frac{1}{2}$ inches (2–3 Cm.) long, and about $\frac{2}{5}$ inch (1 Cm.) broad, vary in shape between oval, lance-oval, and lanceolate, and are acute or rather pointed, mucronate, on the under side somewhat hairy or nearly smooth, and are rather thick in texture. The stipules are subulate, and the fruit is broadly oblong, slightly bent, about 2 inches (5 Cm.) long, and contains about six seeds.

FIG. 267.

Cassia acutifolia, *Del.*

FIG. 268.

Cassia obovata, *Colladon*.

CASSIA OBOVATA, *Colladon* (*C. Senna*, *Forskål*; *C. obtusa*, *Wallich*; *C. obtusata*, *Hayne*).

Senna obovata, *Batka*). It is found in Arabia and in Africa from Egypt southward, in Nubia, Abyssinia, and Southern Africa, and westward to Tripoli and Senegal. The leaflets are in four to seven pairs, obovate or oblong-obovate, mucronulate, clothed with few appressed hairs or nearly smooth. The stipules are linear-lanceolate, acute and rigid, and the legume is curved, rounded at both ends, 1½ inches (38 Mm.) long, and contains about ten seeds. *Batka* distinguishes three varieties: α *genuina*, with the leaflets rounded or mucronulate at the apex; β *obtusata*, with the leaflets more blunt; and γ *platicarpa*, with shorter racemes and broader and less curved legumes than the preceding. *C. obovata* is cultivated, and has been naturalized in Jamaica. It is mentioned by the British Pharmacopœia as one of the sources of Alexandria senna, but its leaflets are now rarely met with in the drug.

CASSIA ELONGATA. *Lénaire* (*C. angustifolia*, *Vahl*, *C. lanceolata*, *Wight et Arnott*, *C. acutifolia*, *Nees*, *C. medica*, *Porskal*, *C. medicinalis*, *Bischoff*, *Senna officinalis*, *Roxburgh*, *S. angustifolia*, *Batka*). It is found in South-western Arabia, along the Somali coast of Africa, and eastward in Northern India. The leaflets are in four to eight pairs, are from 1 to 2 inches (25 to 50 Mm.) long, ½ to ¾ inch (12–19 Mm.) broad, vary in shape from narrow-lanceolate to lance-ovate and oblong-ovate; are narrowed above to the mucronate apex, slightly pubescent, and beneath somewhat glaucous. The stipules are narrow, and the legumes oblong or oval, about 2 inches (5 Cm.) long, and contain about eight seeds. *Batka* distinguishes three varieties—namely, α *dilatata* (α *genuina*, *Bischoff*), the leaflets broadest above the base and in the middle, and gradually tapering to the apex; β *arcuata* (β *Royleana*, *Bischoff*), the leaflets narrowed at the base, broadest below the middle, and more pointed and thinner than in the preceding variety; γ *genuina* (γ *Ehrenbergii*, *Bischoff*), the leaflets narrower than the preceding varieties, linear-lanceolate, and pointed. The variety β seems to be a form produced by cultivation at Tinnevely in Southern India.

FIG. 269.

Cassia elongata, Lém.

Collection.—In Nubia the collection of senna appears to be carried on in the same manner now as it was at the time when Nectoux visited that country near the close of the last century. In the month of September, after the termination of the rains, the natives cut down the shrubs and dry them on the rocks in the sun, after which they are stripped. The leaves are then packed in bags made of palm-leaves and transported by camels to the Nile, and thence to Cairo and Alexandria, from which port the drug derives its name and finds its way into commerce. A second crop, which is frequently very limited, is obtained about the middle of March, when the fruit ripens.

The United States imported 114,766 pounds of senna in 1875, and 512,124 pounds in 1881.

Description.—The pharmacopœial varieties of senna are—

1. **ALEXANDRIA SENNA.** This variety has been very variable in quality, and sometimes much broken up and mixed with leaf-stalks and fragments of the branches. Leaflets of the three species of *Cassia* described above have at times been observed in the commercial article, but of late years the drug consisted chiefly of the leaflets of *C. acutifolia*, to the exclusion of the other species. Recently (1878), however, we have seen samples containing again, to a limited extent, the leaflets of *C. obovata*, which is called by the Arabs *senna baladi* (*wild senna*), and is regarded in Egypt as much less valuable than the *senna jebeli* (*mountain-senna*), the *C. acutifolia*. Alexandria senna requires to be freed from argel-leaves (not by *P. G.*) and from discolored leaves, and frequently needs sifting and picking in order to separate stalks, foreign leaves, fruits, and earthy impurities (see below). Including finely-broken leaves, such impurities amount sometimes to from 40 to nearly 60 per cent. of the weight of the drug. Alexandria senna is of a pale-green color, of a thickish texture, plainly veined, finely hairy, mainly on the midrib, and possesses a somewhat tea-like odor and a mucilagi-

FIG. 270.

Tripoli Senna: leaflets and legumes.

nous afterward bitterish and nauseous taste. Like the other varieties of senna, the leaflets are oblique and uneven toward the base.

Identical with the preceding in its botanical origin is *Tripoli senna*, which comes by caravans from the interior of Africa to Tripoli, but rarely reaches this country.

FIG. 271.

Solenostemma argel, Hayne.

It is frequently much broken up, and even discolored, but otherwise free from foreign leaves, though not from other impurities, including legumes, stalks, and earthy matters.

2. INDIA SENNA consists solely of the leaflets of *C. angustifolia*, but is met with of different qualities, the handsomest being—

Tinnevely senna. It is the kind recognized by the Br. P. as *Senna indica*, and consists of the carefully-dried and fully-matured leaflets of the variety *arcuata*, which are dull-green in color, smooth or slightly pubescent beneath, and are free from stalks, legumes, broken or discolored leaves, and other impurities. Their odor is similar to that of *Alexandria senna*, but the taste is more mucilaginous and less nauseous.

East India or *Bombay senna* has the same origin, but is less carefully dried, and frequently contains smaller and somewhat discolored leaflets. It is not unfrequently sold here as *Tinnevely senna*.

Arabian or *Mecca senna*, also sold as *Bombay senna*, is collected and dried with still less care, and is often mixed with brown leaflets and with legumes.

Allied Drugs and Admixtures.—*CASSIA (SENNA, Balka) PUBESCENS*, R. Brown, s. C. Schimper, *Stuedel*. The leaflets are about an inch (25 Mm.) long, oval or ovate, obtuse, mucronate, soft-hairy on both sides, and ciliate on the margin. They have occasionally been met with in *Mecca senna*.

CASSIA BREVIPES, *De Candolle*. The leaflets were sent from Central America to Great Britain in 1875; they resemble *India senna*, but have three veins running nearly parallel from the base to the blunt apex, and their infusion was found by Holmes to be destitute of purgative properties.

CASSIA MARILANDICA, *Linne* (U. S. 1870); *Folia sennæ Americanae*.—*Séné Américain*, *Fr.*: *Amerikanische Senna*, *G.* Bentley and Trimen, *Med. Plants*, 88.—This perennial plant is found in low grounds and along streams from the New England States and New York south to the Carolinas and west to the Mississippi. It produces erect branching stems 3 to 5 feet (.9–1.5 M.) high, and has pinnate leaves on petioles 1 to 2 inches (25–50 Mm.) long and with a nearly sessile gland near the base on the upper side, six to nine pairs of leaflets, numerous pedunculate erect racemes near the top of the branches, showy yellow or whitish flowers with dark veins, and legumes which are finally smooth, linear, compressed, often curved, and somewhat sinuate on the raised edges; the ovate oblong seeds are separated by transverse dissepiments. It flowers in August and ripens its fruit in October. It belongs to the subgenus *Chamaesenna*, which differs from *senna* mainly in the narrow glands upon the petioles and in the dehiscent legumes. The leaflets are 1 and occasionally 2 inches (25 or 50 Mm.) long, about $\frac{1}{2}$ inch (12 Mm.) wide, on short foot-stalks, smooth, ovate-oblong to elliptic, obtuse, uneven at the base, green above and paler beneath. Collected in summer, the leaflets have an herbaceous odor, but if collected in September or the beginning of October, after the plant is out of bloom, they acquire a distinct senna odor. They are thinner in texture and larger than *Alexandria senna*, and lose on drying about 70 per cent. of moisture. The analyses of J. J. Martin (1835) and E. L. Perot (1855) did not throw any light upon the active principle, assuming that the leaves contain such. The usual constituents of leaves, a minute quantity of volatile oil, some fat, resin, mucilage, etc., were found, in addition to a complex body resembling the formerly so-called cathartin of senna.

SOLENOSTEMMA (CYNANCHUM, Delile) ARGEL, Hayne, s. *Cyn. oleaefolium*, *Necton* (nat. ord. *Aselepiadaceæ*). The leaves constitute the principal adulteration of *Alexandria senna*, aside from stalks and earthy admixtures. They resemble senna-leaves closely in size, shape, and color, but are readily distinguished by the indistinctness of their lateral veins and by their even base; they are also more leathery in texture, have a wrinkled surface, are grayish-green, pubescent, and of a decidedly bitter taste. They are often accompanied by the flower-buds of the same plant, by the whitish flowers, or occasionally by the slender pear-shaped fruit, which is $1\frac{1}{2}$ inches (38 Mm.) long, and contains numerous hairy tufted seeds. The plant inhabits Upper Egypt, but is never collected with senna, the addition being made to supply the demand.

FIG. 272.

Tephrosia apollinea, D. C.

The leaflets of *Tephrosia (Galega, Delile) apollinea*, *De Candolle*, a leguminous plant of Southern Europe, are said to have been sometimes noticed as an adulteration of senna; they are somewhat uneven at the base, but their shape is obovate and they are emarginate at the apex.

The leaves of *Coriaria* are described on page 509, and the leaflets of *Colutea* on page 491; they are rarely, if ever, met with now as adulterations of senna.

GLOBULARIA ALYPUM, *Linne* (nat. ord. *Globulariaceæ*). The shrub is indigenous to Southern Europe; the leaves, which are used as a substitute for senna, are nearly sessile, obovate-oblong, entire or slightly toothed, finely granular, and on the lower side bluish-green. Walz found in the leaves a peculiar tannin and an amorphous bitter principle, *globularin*, which is precipitated by tannin, is soluble in water, alcohol, ether,

and chloroform, and is a glucoside. Heekel and Schlagdenhauffen (1882) found its composition to be $C_{13}H_{20}O_8$, and that of its decomposition-product, globularetin, $C_{19}H_{26}O$: the latter, heated with alkalis, yields cinnamic acid, which also exists in the leaves, together with mannit, wax, etc.

Constituents.—Senna-leaves have been frequently subjected to analysis, but the results are even at the present time not entirely satisfactory. Lassaigne and Feneulle's *cathartin* was found by Heerlein (1843) to be destitute of active cathartic properties. Winckler (1840) obtained the bitter principle again in an impure state; but in the same year *chrysoretin* was isolated by Bley and Diesel, and this substance was subsequently (1857) pronounced by C. Martius to be identical with *chrysophanic acid*, and to be mixed with *phæoretin* and fatty acids. Bourgoin (1871) ascertained cathartin to be free from cathartic acid, but to be a mixture of sugar, chrysophanic acid, and *chrysophanin*, which latter is white, soluble in water, insoluble in alcohol, and is not precipitated by lead acetate. Ludwig (1864) obtained an acid and a bitter principle, both of which are absorbed by charcoal, but *sennacrol* is soluble and *sennapierin* is insoluble in ether. From the investigations of Dragendorff and Kubly (1866) and Groves (1868) there can be no doubt that the cathartic properties of senna reside mainly, if not exclusively, in the calcium and magnesium salts of *cathartic acid*, which are insoluble in alcohol, but soluble in water, and may be obtained by precipitating a concentrated infusion of senna with an equal bulk of absolute alcohol; the liquid filtered from the precipitated mucilage and salts is mixed with more absolute alcohol as long as a precipitate is produced. This precipitate is washed with alcohol, dissolved in a little water, freed from albumen by a few drops of hydrochloric acid, and the filtrate completely precipitated by the addition of more hydrochloric acid; the impure cathartic acid thus obtained is purified by dissolving in 60 per cent. alcohol and precipitating by ether. T. B. Groves (1868) takes advantage of the colloidal properties of cathartic acid, and purifies it by dissolving the crude cathartate in moderately strong hydrochloric acid and subjecting the solution to dialysis on a diaphragm of parchment-paper. Thus obtained, cathartic acid contains nitrogen and sulphur, and is a brown, and after drying a black, amorphous substance, which is insoluble in water, but dissolves in alkalis, from which solutions it is again precipitated by acids. The cathartates of the alkalis and alkaline earths are soluble in water, but insoluble in alcohol. On boiling the alcoholic solution of cathartic acid with hydrochloric acid it yields 34 per cent. of glucose and 65 of *cathartogenic acid*, which is a yellowish-brown powder insoluble in water and ether. According to Groves, the long-continued action of heat on cathartates exposed to air in watery solution decomposes them, rendering them inert; organic acids, added to the aqueous solutions of cathartates, precipitate cathartic acid, but, unlike the mineral acids, do not decompose it on boiling. Dragendorff and Kubly obtained also a dextrogyrate saccharine substance, *cathartomannit*, in verrucose crystals, and regard the yellow coloring matter as similar to, but distinct from, chrysophanic acid; it is probably the glucoside *chrysophan*. (See RHEUM.) Keussler (1878) prepared from senna chrysophanic acid and inactive cathartomannit. L. Siebold (1875) found that senna-leaves treated with strong alcohol are rather less purgative than the unextracted leaves, but he confirmed the earlier observations, that the alcoholic extract is destitute of such action, though it contains the griping principles. Diehl (1875) made similar observations.

Pharmaceutical Uses.—SPECIES LAXANTES, *P. G.* Senna-leaves 16 parts, elder-flowers 10 parts, fennel and anise each 5 parts, are cut, bruised, and mixed with 4 parts of cream of tartar. A uniform mixture cannot thus be obtained, since the powdered cream of tartar separates readily; it is therefore recommended by Thanisch to moisten the unbruised fennel and anise with simple syrup, and then to mix them with the cream of tartar, which after drying will adhere. Another advantage is that the volatile oils will then not be exposed to the air.

SPECIES LAXANTES ST. GERMAIN. The formula is practically identical with the preceding, except that senna-leaves, previously exhausted by alcohol, are used.

Off. Prep.—Confectio sennæ, *U. S., Br.*; Extract. sennæ fluid., *U. S.*; Infus. sennæ comp., *U. S., Br.*; Mistura sennæ comp., *Br.*; Pulv. glycyrrhiæ comp., *Br.*; Syrup. sarsaparillæ comp., *U. S.*; Syrup. sennæ, *U. S., Br.*; Tinct. sennæ, *Br.*

Physiological Action.—A decoction of senna injected into the veins of a dog produces agitated movements of the abdomen and bilious vomiting. It readily purges swine, dogs, cats, and horses. In man an infusion of senna injected into the veins has occasioned both vomiting and purging. Some persons are so susceptible to its action as to be purged even by the odor of senna or of its infusion. It renders the milk of a nursing woman purgative to her infant. It is very apt to create flatulence, nausea, and colic, unless asso-

ciated with some lenitive or aromatic substance. It produces yellow stools, and its action is not followed by constipation. It never occasions hypercatharsis. Its operation is said to be promoted by bitter medicines, such as colombo, and hence it is a valuable purgative when constipation is associated with debility of the bowels. Cathartic acid has a sour and somewhat astringent taste. It passes through the system without decomposition, and affects the milk of nursing women like senna itself. In the dose of $1\frac{1}{2}$ to 3 grains (Gm. 0.10–0.20) it occasions griping and liquid yellow stools.

Medical Uses.—The uses of senna were learned from the Arabians, who employed it in various local affections, especially of the skin. Their later authorities refer to its tendency to gripe, to obviate which they recommend its association with violets, prunes, and other lenitives. Even now it is seldom given alone, but generally with some corrective of its griping qualities, as with coriander in the simple infusion, or with tamarinds, or with Epsom or Rochelle salt, manna, and fennel-seed, as in the infusion known as the “black draught.” Care should be taken not to let the leaves macerate too long, nor to compress them when the liquid of the infusion is decanted, lest their acrid principle be taken up and produce griping. The dose of either of these infusions is from 2 to 4 fluidounces (Gm. 64–128), repeated every two or three hours until its purgative effects begin to be felt. The infusions are better purgatives than the simple tincture, for water extracts from senna a larger proportion of its purgative principle than alcohol. An excellent laxative is the compound powder of liquorice, whose active ingredient is senna, as it also is of “Tamar Indien.”

American senna is identical with Alexandria senna in the mode of its operation, but a dose one-third larger of it is required. At best, it is but a poor substitute for the African drug.

SERPENTARIA, U. S.—SERPENTARIA.

Serpentariae rhizoma (radix), Br.—*Virginia snakeroot*, *Serpentary-root*, E.; *Serpentaire (Couleurée) de Virginie*, Fr.; *Virginische Schlangenzurzel*, G.

The rhizome and rootlets of *Aristolochia* (Endodeca, *Klotzsch*) *Serpentaria*, *Limé*, and of *Aristolochia reticulata*, *Nuttall*. Bentley and Trimen, *Med. Plants*, 246.

Nat. Ord.—*Aristolochiaceæ*.

Origin.—The two plants from which Virginia snakeroot is derived are perennial herbs, with slender erect zigzag stems about 12 inches (30 Cm.) high, alternate cordate or cordately-ovate leaves, and with purple flowers, which grow on slender flexuose branches from the lower nodes and have the tube of the perianth inflated at both ends and bent like the letter S. *Arist. Serpentina* has the leaves petiolate, pointed, thin, and somewhat pubescent, and is found in rich woodlands from Connecticut westward to the Mississippi, and southward in the middle and southern part of the United States; it is not common except near the Alleghany Mountains. The variety *hastata* (*Arist. sagittata*, *Muhlberg*, *Ar. hastata*, *Nuttall*) is smaller, more slender, has narrow lance-oblong auriculate leaves, and grows in South Carolina and westward. *Arist. reticulata* has the leaves subsessile, obtuse, thickish, reticulate, and hirsute, and is indigenous to Louisiana and Texas.

Description.—Virginia snakeroot consists of a rhizome which is about an inch (25 Mm.) long, $\frac{1}{2}$ inch (3 Mm.) thick, is bent up and down, and bears on the upper side the short approximate stem-remnants, which are flat or slightly convex above; below and on the sides are numerous thin branching rootlets, 3 to 6 inches (7–15 Cm.) long, and matted together. It is of a dull yellowish-brown color, and has an aromatic camphoraceous odor and a bitterish, aromatic, camphoraceous, and somewhat terebinthinate taste. The drug derived from *Ar. reticulata* is sometimes distinguished in commerce as *Red River* or *Texas snakeroot*; it closely resembles the preceding, but has a somewhat thicker rhizome and coarser, rather longer, and less interlaced rootlets. On transverse section the rhizome is seen to consist of a thin bark containing some oil-cells, and an eccentric wood with broad, slightly-curved medullary rays, and enclosing a pith which is near the upper side. The rootlets have a thick bark containing scattered oil-cells and a thin angular central ligneous cord.

Constituents.—Bucholz (1807) determined the presence in serpentary of about $\frac{1}{2}$ per cent. of volatile oil and of resinous, extractive, and mucilaginous matters. The *volatile oil* is brownish-yellow, lighter than water, and has an odor and taste resembling those of a mixture of valerian and camphor. The *bitter principle* was obtained by Chevallier (1820) by precipitating the decoction with lead acetate, exhausting the precipitate with hot alcohol, evaporating, and treating the residue with water, which dissolves

the bitter principle. Feneulle (1826) found the bitter principle in the filtrate from the precipitate occasioned in the decoction by lead acetate. It is yellow, amorphous, soluble in water and alcohol, yields precipitates with tannin and various metallic salts, and appears to resemble the bitter principle contained in the rhizome of *Aristolochia Clematidis*, *Linné*. A small quantity of tannin, malic acid, albumen, sugar, and other common constituents are also contained in serpentary. According to T. S. Wiegand (1844), Red River snakeroot has the same constituents, but is more mucilaginous and yields a somewhat larger proportion of volatile oil.

Impurities and Adulterations.—As found in commerce, serpentary frequently has portions of the stem attached, sometimes with leaves and with the six-sided and six-celled capsules. Ginseng-root and the rhizomes of cypripedium and of hydrastis are occasionally met with as accidental impurities, but Milleman (1874) also observed hydrastis as an evident intentional adulteration of serpentary. *Spigelia* is occasionally used for the same purpose. All these impuri-

of rhizome.

ties and adulterations may, however, be easily identified from the characters of these drugs, as described elsewhere.

Off. Prep.—Extract. serpentariæ fluid., *U. S.*; Infusum serpentariæ, *Br.*; Tinct. cinchonæ comp., Tinct. serpentariæ, *U. S., Br.*

History.—Serpentaria was used by the American aborigines as a cure for snake-bites (whence its name) and by the early colonists as a tonic and stimulant. It was introduced into medicine in London in 1633. Sydenham alludes to it as a remedy for intermittent fever when infused in white wine and taken so as to produce sweating before the paroxysm.

Medical Action and Uses.—In large doses it occasions nausea, eructation, vomiting, and flatulence, but not diarrhœa; it gives rise to some fulness of the head and quickens the circulation. In certain states of the system it promotes perspiration, but experiments with it on healthy persons give no indication of its virtues in disease. They are manifested in *typhus* and *typhoid fever*, and in the *typhoid state* generally, whenever the pulse is feeble or irregular, the skin cool and clammy, the mouth fuliginous, the eyes injected and dull, and the mind delirious or stupid. When, in addition, the urine and feces are dark and fetid, the skin covered with ecchymoses, etc., serpentaria is indicated, and with it cinchona and alcohol. Such an association of medicines exists in the compound tincture of cinchona, which from the days of Huxham, who invented it, has been an habitual remedy in these affections. In *typhoid pneumonia* serpentaria is much relied on, and in low forms of *diphtheria*.

The dose of serpentaria in powder is from 10 to 30 grains (Gm. 0.60–2). The infusion, which is official (*Br.*), is the best simple preparation of the medicine, but the fluid extract, the tincture, and especially the compound tincture, are much more commonly employed.

SEVUM, U. S.—SUET.

Serum preparatum, Br.; *Sebum ovile (ovillum)*, P. G.—*Prepared suet*, *Mutton suet*, E.; *Suif de mouton*, Fr.; *Talg*, *Hammeltalg*, G.

The purified internal fat of the abdomen of *Ovis Aries*, *Linné*, the sheep.

Class Mammalia. *Ord.* Ruminantia.

Origin.—The sheep is domesticated everywhere, and is by zoologists considered to be a variety either of the *argali* of Siberia, *Ovis Ammon*, *Linné*, or of the South European *muflon*, *Ovis Musimon*, *Linné*. The part employed is the internal fat of the abdomen, which is cut into small pieces, melted by the aid of a moderate heat, and strained.

Properties.—Mutton suet is a white, smooth, solid, nearly inodorous fat, which on exposure to air gradually becomes rancid. It has a neutral reaction and bland taste, melts between 46° and 50° C. (114° and 122° F.), and congeals between 36° and 40° C. (96.8 and 104° F.), with a rise of temperature of nearly 5° C. (9° F.), fresh suet having the lower melting- and congealing-point. It dissolves in 44 parts of boiling alcohol of specific gravity .821, but is insoluble in cold alcohol; on warming equal parts of suet and alcohol, agitating thoroughly, and afterward cooling, the clear alcoholic liquid does not become turbid on the addition of water (absence of fat acids). According to Lecanu, suet requires over 60 parts of cold ether for solution; it is slowly soluble in 2 parts of benzin, and crystallizes again from this solution on keeping it for some time in a closed vessel.

Composition.—According to Chevreul and Heintz, mutton suet consists of 70 per cent. of *stearin* and *palmitin*, 30 per cent. of *olein*, and a trace of *hircin*; the latter is the glyceryl compound of *hircic acid*, which is a colorless oil, of a peculiar goat-like and acetous odor, has a strong acid reaction, and is freely soluble in alcohol. The olein prepared by expressing the suet is nearly colorless, has a slight odor, and dissolves in about 1½ parts of boiling absolute alcohol.

Off. Prep.—*Cerat. resine comp.*, U. S.; *Emplast. cantharidis*, Br.; *Ungu. hydrargyri*, U. S., Br.; *Ungu. picis liquidæ*, U. S.

Medical Action and Uses.—Suet, when perfectly fresh, forms a suitable dressing for blistered and other excoriated surfaces, but it is very apt to grow rancid, and is then decidedly irritant. It is used as an ingredient of various ointments, cerates, and plasters, and gives them a firmer consistence than they would derive from lard.

SIMARUBA.—SIMARUBA.

Simarouba, Fr.; *Ruhrrinde*, G.

The bark of the root of *Simaruba officinalis*, *De Candolle* (*Sim. amara*, *Aublét*, *Sim. guianensis*, *Richard*, *Quassia Simaruba*, *Linné filius*), and the bark of *Simaruba medicinalis*, *Endlicher* (*Sim. amara*, *Hoyne*, *Sim. glauca*, *De Candolle*, *Quassia Simaruba*, *Wright*). Bentley and Trimen, *Med. Plants*, 56.

Nat. Ord.—Simarubaceæ.

Origin.—This first species is a native of Guiana, Venezuela, and Northern Brazil. It is 60 to 70 feet (18–21 M.) high, and has some resemblance to the ash. The leaves are alternate, pinnate, and have from eight to twelve or sixteen oval-oblong, obtuse or mucronate, entire, and short-stalked leaflets about 4 inches (10 Cm.) long. The diœcious or monœcious flowers are small, white, and are aggregated in few-flowered clusters on the slender alternate branches of an elongated racemose inflorescence. The second species is indigenous to Southern Florida, the West India Islands, and Central America; it is the *stave-wood* or *mountain-damson* of Jamaica, and differs from the preceding chiefly by the smaller wedge-oblong leaflets and by the larger compressed drupe.

Description.—*Simaruba*-bark comes in curved or quilled pieces, which are several feet long, 2 to 3 inches (5–8 Cm.) wide, and about ¼ or sometimes ½ inch (3–6 Mm.) thick. Its external surface is uneven, rough, and wrinkled, covered with a yellowish or brownish suberous layer, or, if this is removed, of a grayish-brown color. The coarsely fibrous bast-layer is thick and dull-brownish; the inner surface is of a lighter color and striate. The bark is very tough, and breaks with difficulty in a transverse direction, but may be longitudinally torn, the pieces remaining united by some of the long and tough bast-fibres. When cut transversely the outer tissue is seen to contain scattered brown-yellow granules consisting of groups of stone-cells, and the inner

FIG. 276.

Simaruba-Bark: transverse section, magnified.

layer is radially striate in an oblique direction, caused by the long and wavy bast-wedges. Simaruba-bark is without odor and has a strong and persistent bitter taste.

The bark of the second species is very similar to the one described, but is paler, usually thicker, of a light yellowish- or reddish-brown color, has a smoother inner surface, and is equally bitter.

Constituents.—Simaruba-bark was analyzed by Morin (1822), and found to contain a little volatile oil, resin, traces of gallic acid, malate and oxalate of calcium, and other salts. The bitter principle is not precipitated by lead salts; it was obtained as an extract-like mass, and is supposed to be identical with *quassin*.

Allied Drugs.—Most if not all the trees belonging to the order of Simarubaceæ have a very bitter wood and bark. (See QUASSIA, page 1264.)

SIMABA CEDRON, *Planchon*, and **SIM. FERRUGINEA**, *St. Hilaire*. These trees are indigenous, the former to Colombia and the latter to Brazil; they resemble the above, but have hermaphrodite flowers. All their parts are very bitter. The fruit is a pear-shaped drupe of the size of a hen's egg, and contains an oblong seed about $1\frac{1}{2}$ inches (38 Mm.) long and about $\frac{1}{2}$ inch (20 Mm.) broad; the cotyledons are plano-convex, grayish or brownish, hard, inodorous, and very bitter. Lewy (1851) exhausted the seeds with ether, and afterward with alcohol, from which very bitter silky needles of *cedrin* crystallized. Tanret (1880) regards it as identical with his *valdivin*, obtained from the fruit of *Simaba Valdivia*, *Planchon*, by treating the alcoholic extract with chloroform and crystallizing from boiling water. Valdivin, $C_{36}H_{48}O_{20} \cdot 5H_2O$, melts at $230^{\circ}C$, is insoluble in ether, easily soluble in alcohol and chloroform, and soluble in 600 parts of cold water; this solution foams on agitation. Alkalies decompose the principle, which is emetic.

SAMADERA INDICA, *Guertner* (Niota pentapetala, *Lamarck*), is a medium-sized East Indian tree, all parts of which are very bitter. The bark is $\frac{1}{8}$ to $\frac{1}{4}$ inch (4–6 Mm.) thick, red-brown, smooth, internally whitish dotted, and has a short and finely fibrous fracture. The fruit is obliquely ovate, compressed, about 2 inches (5 Cm.) long, and contains a brownish curved seed. De Vrij (1872) expressed from the seeds 33 per cent. of a light-yellow bitter oil which contains, according to Oudemans, 84 per cent. of olein and 16 per cent. of palmitin and stearin. The bitter principle *samaderin* was yellowish, and soluble in water and alcohol, and amorphous: Tonningen (1858) had obtained it from the seed and bark in white scales, which became yellow with nitric or hydrochloric acid and violet-red with sulphuric acid.

CASCARA AMARGA, or **HONDURAS BARK**. Under this name a bitter bark has been introduced which has been referred to a species of *Picramnia*. It is about $\frac{1}{4}$ inch (4 Mm.) thick, has a gray-brown, smoothish, thick cork, and is internally deep-brown, with numerous white dots of groups of stone-cells. F. A. Thompson (1884) obtained 4.5 per cent. of ash and 3 per cent. of impure amorphous alkaloid having a sweetish afterward bitter taste.

Medical Action and Uses.—Like quassia, to which it is nearly allied, simaruba is intensely bitter and also slightly aromatic. In moderate doses its action is that of the simple bitters; in large doses, like them also, it operates as an emetic and purges. In South America, its native country, it is said to have been long employed as a specific for dysentery, and it was first introduced into Europe in the beginning of the eighteenth century for a like purpose. Although it has ceased to be used in *acute dysentery*, it is occasionally employed as a bitter tonic in the decline of that disease and in *dyspepsia*. At one time it was regarded chiefly as an emetic, and it was even proposed to use it as a substitute for ipecacuanha. It has also been prescribed in various conditions of debility associated with scrofula, chronic diarrhoea, etc. At present it is hardly ever used.

Simaruba may be given in powder in the *dose* of from 10 to 30 grains (Gm. 0.60–2), but this form is ineligible, owing to the difficulty of reducing the bark to powder. It is best administered in a decoction or infusion made with 2 drachms of the bark in a pint of water (Gm. 8 in Gm. 500).

Simaba cedron is used as a bitter tonic in New Granada, as a fever medicine also, and as an antidote for the bites of poisonous animals (*Amer. Jour. Phar.*, lii. 89). According to some experiments made in Paris, *cedrine* kills a rabbit in the dose of 10 Mgm. ($\frac{1}{6}$ grain), and about half that quantity administered hypodermically to man occasions vertigo. It is denied that it is an antidote to snake-poison, but affirmed that it is a febrifuge, although feebler than quinine (*Bull. de therap.*, c. 328).

SINAPIS ALBA, U. S.—WHITE MUSTARD.

Semen crucæ.—Yellow mustard-seed, E.; *Moutarde blanche*, Fr.; *Weisser Senf*, G.

The seed of *Sinapis* (*Leucosinapis*, *Spach*. Brassica, *Hooker filius et Thompson*) alba, *Linné*. Bentley and Trimen, *Med. Plants*, 23.

SINAPIS NIGRA, U. S.—BLACK MUSTARD.

Sinapis nigrae semina, Br.; *Semen sinapis*, P. G.—*Moutarde noire (grise)*, Fr.; *Schwarzer Senf*, G.

The seed of *Sinapis* (*Brassica*, Koch) *nigra*, Linné, s. *Brassica sinapiodes*, Roth. Bentley and Trimen, *Med. Plants*, 22.

Nat. Ord.—Cruciferae, Siliquosae.

Origin.—Both white and black mustard have escaped from cultivation in the United States, and are sometimes found wild here. Both are indigenous to Southern Europe and Western Asia, and now grow as weeds throughout a great portion of Europe and Middle Asia, black mustard extending farther to the north, and white mustard farther eastward to China. The two plants are annuals, and have thin, branching, spindle-shaped roots, lyrate-pinnatifid lower leaves, compact and finally elongated racemes of yellow flowers, and beaked three- to six-seeded pods. *White mustard* is retrorsely hairy, has the upper leaves stalked, three-lobed and toothed, and the pods hairy, ascending, beaked by the seeds, and furnished with a prominent sword-shaped beak, containing a seed at its base. *Black mustard* is larger, 3 or sometimes 4 feet (.9 or 1.2 M.) high, smooth above, has the upper leaves slightly toothed or entire, and produces smooth linear pods which are appressed to the axis and furnished with a short beak. During the preceding eight years the importation into the United States of mustard-seed fluctuated between 823,558 pounds in 1878 and 4,507,975 pounds in 1882, and that of ground mustard between 399,244 pounds in 1878 and 555,535 pounds in 1881.

White and black mustard-seeds, powdered and mixed, are admitted by the British Pharmacopœia together as *sinapis*, but separately by the U. S. and French Pharmacopœias. The German Pharmacopœia recognizes black mustard-seed alone as *Semen sinapis*.

Description.—1. **WHITE MUSTARD-SEED.** The seeds are globular or nearly so, about $\frac{1}{12}$ inch (2 Mm.) in diameter, weigh about .005 Gm., and are on one end marked with a small circular hilum and on the inner side with two shallow grooves. The testa is of a yellowish or pale grayish-brown color, very finely pitted and somewhat rough. The seed is inodorous, but when masticated has a pungent and acrid taste. Its internal structure is identical with that of the next.

FIG. 277.

Black Mustard-Seed: entire, magnified.

FIG. 278.

Embryo.

FIG. 279.

Transverse section.

2. **BLACK MUSTARD-SEED** resembles the preceding in shape, but has only a diameter of $\frac{1}{25}$ inch (1 Mm.) and an average weight of .001 Gm., is blackish-brown or deep reddish-brown, has the testa covered with shallow pits, and when crushed and macerated with water acquires a strong and pungent odor.

Both seeds, after the integuments have been removed, contain an embryo having the shape of the seed, the cotyledons of which are folded along their midribs, one covering the other, while the radicle is turned back and enclosed between the folds of the inner cotyledon. This arrangement is well shown on a transverse section of the seed, which exhibits on one side the round radicle near and between the edges of the plano-convex folds of the inner cotyledon, and these are surrounded by the concavo-convex folds of the outer cotyledon. In both seeds the embryo is yellow and very oily, and imparts to the powder of white mustard a dull pale-yellow, and to that of black mustard a yellowish-green color.

Constituents.—Both seeds are free from starch, and when crushed and subjected to pressure yield from 20 to 25 per cent. of a yellow or brownish-yellow fixed oil, which congeals between -15° and -17.5° C. (5° and 5° F.) to a butyraceous mass. This fixed oil of mustard does not readily turn rancid, has a bland taste, and consists of olein with some stearin and the glycerides of *erucic acid*, $C_{22}H_{42}O_2$, and of *behenic acid*, $C_{22}H_{44}O_2$ (p. 1088), but when expressed between heated plates from black mustard it has

to some extent the pungent odor and taste of these seeds after maceration in water. The oils have the specific gravity .916, and give with sulphuric acid a green or blue-green afterward brown color, and with fuming nitric acid a red color. Erucic or *brassic* acid forms white shining tasteless needles which fuse at about 34° C. (93.2° F.). It was discovered by Darby (1849), who isolated also another fatty acid, *sinapoleic acid*, which, according to Städeler (1853), has the formula $C_{20}H_{38}O_2$. The two kinds of mustard-seed contain a considerable amount of mucilage in the epidermis, and various proteids, the most interesting of which is *myrosin*; and this is obtainable, according to Bussy (1839), from the cold infusion of white mustard by concentrating it below 40° C. (104° F.) and precipitating the syrupy liquid with not too large a quantity of alcohol. Myrosin acts as a ferment upon two distinct principles, one being contained in white and the other in black mustard, and yields among their products of decomposition those compounds to which the acrid and pungent properties of both seeds are due. Myrosin is coagulated by heat and by alcohol; hence black mustard introduced into boiling water does not yield the volatile oil. Both mustard-seeds yield from 4 to 5 per cent. of ash, containing 37.4 per cent. of phosphoric acid.

The principle of white mustard yielding the acrid compound was fully investigated by H. Will (1870), and named by him *sinalbin*, $C_{30}H_{44}N_2S_2O_{16}$. It had been previously obtained in a nearly pure state, and was experimented with by Henry and Garot, Boutron, Robiquet, Winckler, Babo, and others, being described as *sulphocyanide of sinapine*, *sulpho-sinapisin*, *sinapin*, and under various other names. Sinalbin is obtained from white mustard which has been deprived of its fixed oil by exhausting it with boiling alcohol, from which it crystallizes on cooling. When pure it forms small glass-like inodorous bitter prisms which are freely soluble in water, but sparingly soluble in cold alcohol, and insoluble in ether, oil of turpentine, and bisulphide of carbon; it is perfectly neutral, is not colored by ferric chloride, yields white precipitates with corrosive sublimate and nitrate of silver, is colored yellow by traces of alkalies, and by myrosin is decomposed into sugar, acid *sulphate of sinapine*, $C_{16}H_{23}NO_5 \cdot H_2SO_4$, and *sulphocyanide of acryngl*, $C_7H_7O \cdot NCS$. This last compound is obtainable by agitating the aqueous liquid with ether, on the evaporation of which it remains as a nearly colorless, thick, non-volatile oil, which is readily soluble in alcohol and ether, has a sweetish afterward acrid and biting taste, and possesses epispastic properties; it is not colored red by ferric chloride until after its alcoholic solution has been heated with an alkali and again acidulated. *Sinapine* is an alkaloid which has not been isolated, since it is readily decomposed; the solutions of its salts are colored yellow by alkalies, and on boiling the mixtures yield a strong base, *sinakaline* and *sinapic acid*, the barium salt of which is nearly insoluble in cold water; Von Babo and Hirschbrunn (1852) gave these two compounds the formulas $C_5H_{13}NO$ and $C_{11}H_{12}O_5$.

A principle analogous to sinalbin exists in black mustard, and was recognized by Bussy as a peculiar acid, *myronic acid*, combined with potassium. Although he observed also volatile oil of mustard among its products of decomposition by myrosin, the exact composition and behavior of *myronate of potassium*, for which Will (1870) proposed the name *sinigrin*, were not ascertained until investigated by Will and Körner (1863). Sinigrin is obtained from black mustard exhausted with boiling strong alcohol by treating it with cold water, adding a little barium carbonate to the infusion, evaporating to a syrupy consistence, and boiling this residue repeatedly with 85 per cent. alcohol, on the evaporation of which sinigrin is left. The yield is .5 to .6 per cent. When pure it is in white, silky, inodorous needles, or, if crystallized from water, in short glass-like prisms, has a cooling bitter taste, dissolves in water, is insoluble in chloroform, ether, and benzol, and nearly insoluble in absolute alcohol. When treated with myrosin it is decomposed into *sulphocyanide of allyl* or *volatile oil of mustard*, C_4H_7NS (see page 1088), acid sulphate of potassium, $KHSO_4$, and sugar. The analogous decompositions of the peculiar principles of white and black mustard are explained by the following equations:

Adulterations.—Mustard-seed is not subject to adulteration, but ground mustard is very often mixed with various farinaceous substances, and the cold decoction will then acquire a blue or greenish tint on the addition of an aqueous solution of iodine. Ground white mustard has a dull gray-yellow color, which is often rendered brighter by the addition of turmeric; it will then respond to the test for starch, and will acquire a red-brown color with solution of boric acid or of borax.

Off. Prep.—Cataplasma sinapis, Br.; Charta sinapis, U. S., Br.; Oleum sinapis, Br.

Allied Plants.—BRASSICA (*Sinapis*, *Linne*) *JUNCEA*, *Hooker filius*, is extensively cultivated in Southern Russia, and constitutes the *Sarepta* or *Russian mustard*. It is likewise cultivated in Africa and India, and is exported from the latter country to Europe. The seeds closely resemble those of black mustard and yield the same products.

BR. SINAPISTRUM, *Boissier*, s. *Sinapis arvensis*, *Linne*, called *charlock*, is a European annual, and a troublesome weed in some parts of the United States, and has nearly smooth, dark-brown seeds, which are smaller and less pungent than those of black mustard.

BR. CAMPESTRIS, *Linne*, is extensively cultivated in several varieties, the principal ones being Br. Napus, with glaucous foliage, and Br. Rapa, with green foliage; they yield the various kinds of *turnip*, and the seeds, which are respectively $\frac{1}{2}$ and $\frac{1}{4}$ inch (2 and 1.5 Mm.) thick, and less pungent than black mustard-seed, are used for obtaining the bland yellowish *rape-seed* and *colza oil* (*Huile de navette*, de colza, *Fr.*; *Rüböl*, *Rapsöl*, *Kohlsaatlöl*, *Ger.*). These oils are brownish or greenish-yellow, have a somewhat acrid taste, are more bland after refining, yellow, of about the spec. grav. .913, congeal near -5° C. (23° F.), and are colored green-brown or brownish-yellow by sulphuric acid.

RAPHANUS RAPANISTRUM, *Linne*, is a weed known as *wild radish* and *jointed charlock*. According to Pless (1846), the seeds contain also oil of mustard, but the sulphuretted volatile oil obtained from the *garden radish*, *Raphanus sativus*, *Linne*, appears to be different. The fixed oils expressed from these seeds closely resemble those of mustard-seeds.

History.—Mustard has been used medicinally from the earliest periods. Hippocrates described a variety of its applications, but chiefly as an external or local stimulant to dissipate slight inflammations, diminish coma, allay pain, promote the growth of hair, relieve deafness, etc. Internally, he recommended it as a remedy for intermittent fever. Subsequent ancient writers enlarged its sphere of usefulness, applying it as a counter-irritant in nearly all chronic diseases and painful affections, and using it as an emetic and a vermifuge. They were well acquainted with the fact that a sinapism made with vinegar is weaker than one mixed with water.

Physiological Action.—*On Animals:* Essential oil of mustard is a virulent poison. In rabbits it occasions the following symptoms: great frequency of the heart's action, speedy loss of sensibility and muscular power, feebleness of the heart's pulsations, difficult respiration, repeated convulsions, insensibility, coldness, and death. The odor of the oil is very distinct in the internal organs, the urine has a characteristic smell, and the irritability of the heart and voluntary muscles continues for a long time after death.

On Man: Mustard-seed, taken whole in doses of a teaspoonful three or four times a day, have a laxative action upon the bowels and are discharged without perceptible change. As cases have occurred in which an accumulation of them obstructed the bowel, and as they also may possibly find their way, with fatal effect, into the vermiform appendix, they should be used cautiously and swallowed with a large quantity of water.

Powdered mustard applied to the tongue or throat causes prickling and burning. It promotes the digestion of food, but too much of it or its prolonged use enfeebles the stomach. In large quantities, a teaspoonful or more, diffused through tepid water, it acts as a prompt and efficient emetic. Care should be taken to evacuate all of the mustard swallowed.

Applied as a sinapism to the skin, it produces after several minutes an acute prickling, stinging, and burning pain, the skin grows red, and, if the application is too prolonged, is blistered. The blisters are followed by ulcers which are very difficult to heal. The rapidity and completeness of the effect depend upon the delicacy of the skin to which the sinapism is applied. Hence great caution should be observed in prescribing it for children and females. Gangrene and death have resulted from applying a mustard poultice to the swollen glands of a child's neck.

On the other hand, when the skin is naturally tough or when its vitality is impaired by collapse, chill, or low states of the system generally, sinapisms may fail to exert any influence whatever. In these several cases sinapisms made with water are referred to; those made with vinegar possess very inferior activity, and the mustard is less active in proportion as the vinegar is stronger. This fact, although now generally unknown, the ancients were well acquainted with, as already stated.

The effects of a general mustard bath at 86° F. are singular. At first wandering chills are felt in the loins, back, abdomen, and limbs, followed by a feeling of decided coldness and twitching of the extremities. There is even suffering from a sense of cold. Later, and even after the skin has become red, the sensation of coldness continues until the patient leaves the water, when reaction is speedily established, with stinging and burning of the integument.

Volatile oil of mustard is a powerful irritant. A single drop of it upon the tongue

causes a severe burning pain which extends to the throat, nose, and stomach. Upon the skin it acts promptly as a vesicant and caustic.

Medical Uses.—For internal purposes, and particularly where the whole seed is given, white mustard-seed is to be preferred. In *atonic dyspepsia* with *constipation* it has long been employed with advantage in the dose of a teaspoonful and in a draught of water before or after meals. It prevents flatulence, promotes digestion, and keeps the bowels regular. But, like all condiments, it loses its effect by use. An infusion of mustard has sometimes succeeded in arresting obstinate *hiccough*. It is one of the most prompt and efficient emetics which can be used in cases of *narcotic poisoning*. In the early stage of *delirium tremens* a mustard emetic will sometimes cut short the attack. In *atonic dropsy* mustard whey or an infusion of whole mustard-seed in cider is a diuretic of considerable power. That the active principle of mustard is carried into the circulation is shown by the benefits accruing from the use of white mustard-seed in *chronic bronchitis*, *chronic rheumatism*, and some *cutaneous affections*. This use of the medicine has been condemned as being destitute of a rational basis, but the only rational basis for the use of a medicine is its power to cure, and that is sufficiently attested in the present case.

Externally, oil of mustard has been successfully used in the treatment of *scabies*. But one of the most usual and useful applications of mustard is in the form of poultice, plaster, or bath to produce a lively stimulation, and thereby arouse the nervous system, as in the insensibility of *swooning* and *hysteria*, in which it acts by exciting a sense of pain, and in the *convulsions* of children, in which it stimulates the nervous system and perhaps disperses morbid accumulations of blood in the central nervous organs. In foot-baths it relieves *headache* and cerebral and other internal *congestions*, especially uterine congestion accompanied with *dysmenorrhœa*. Dr. Weber claims to have been remarkably successful in the treatment of *pneumonia* in children by means of the hot mustard bath. He placed the child in a bath-tub filled with water at a temperature of from 100° to 105° F., and had the skin rubbed thoroughly until it began to look red. This process required from 7 to 10 minutes, when the child was wiped dry and put into a bed previously warmed. No ill effects were observed from allowing the genitals to remain unprotected. The bath was repeated, if necessary, as often as every three hours. General baths at a temperature of from 77° to 82° F., containing 2 or 3 ounces of mustard and applied for the space of half an hour, have been used with great advantage in allaying the violence of *insanity*. Large poultices or epithems containing mustard and sinapised hip-baths have been beneficial in analogous conditions. However it may be explained, it is certain that mustard pediluvia, and even mustard plasters employed to relieve pain, frequently induce sleep; indeed, it sometimes happens that the patient falls asleep while the plaster is “drawing,” with the result of producing painful and intractable sores.

When the action of a part is morbidly diminished or that of an internal organ is morbidly increased, as in *retrocedent gout* or *rheumatism*, or where a part is too anæmic for the application of *leeches*, or where a muscle or muscles suffer partial *atrophy*, mustard poultices, etc. are sometimes beneficial.

Every form almost of local pain may be relieved in the same manner as that of sub-acute and chronic *articular rheumatism*, *pleurodynia*, *neuralgia*, *toothache*, *earache*, *flatulent colic*, *muscular rheumatism*, and *dysmenorrhœa*. The same is true of various abnormal discharges, such as *vomiting*, *diarrhœa*, *cholera morbus*, and *dysentery*. In epidemic *cholera* general mustard baths have frequently been found beneficial in the early stages of the disease, and occasionally in the cyanotic stage.

Administration.—Of white mustard-seed 1 or 2 teaspoonfuls in 3 or 4 ounces of water may be taken once a day or oftener. The *infusion* of mustard, for an emetic, is prepared by adding 1, 2, or 3 teaspoonfuls of mustard flour to a pint of warm water. Mustard *whey* is made by adding to a pint of milk mixed with a quart of water 1½ ounces of bruised mustard-seed, boiling the mixture until it is curdled, and straining off the whey. A wine-glassful may be given every hour or two. The *sinapism*, or mustard plaster, is prepared by adding cold or lukewarm water to equal quantities of mustard and wheaten or rye flour, and stirring until a thick paste is formed. This is spread upon linen or other convenient tissue and applied to the skin. It is well to interpose a piece of gauze between the plaster and the body, to prevent the former from adhering. It should remain applied from ten minutes to an hour, according to the degree of its action. The mustard *cataplasm* (*Pharm. Br.*) is an ordinary poultice with which mustard has been mixed; it is intended to maintain a gentler but more prolonged action than the sinapism. “*Mustard-leaves*” should be dipped in water before being applied. Sinapised *pediluvia* are made by adding a sufficient quantity (a tablespoonful or two) of mustard

flour to an ordinary foot-bath. When pediluvia are used as general stimulants, they should be as warm as they can be borne; but when employed as derivatives, especially from the head and chest, their temperature should not exceed that of the blood, or from 98° to 100° F. The *essential oil* of mustard has been prescribed internally in an emulsion in the dose of from $\frac{1}{12}$ to $\frac{1}{4}$ of a drop. It may be used externally as a rubefacient in the proportion of 24 drops of the oil to an ounce (Gm. 1.60 to Gm. 32) of alcohol, or 5 or 6 drops to a fluidrachm (Gm. 0.30 to Gm. 4) of almond oil. Care must be taken to proportion the strength of the liniment to the delicacy of the skin. The best application for the sores produced by mustard is lime-water liniment; if the pain be severe, the part may first be covered with stramonium ointment. Later, poultices of grated raw carrots, and finally oxide of zinc ointment, may be employed.

SODA, U. S., Br.—SODA.

Soda caustica, Br.; *Natrium causticum*, *Natrium hydricum*.—*Caustic soda*, *Sodium hydrate*, E.; *Soude caustique*, Fr.; *Natron*, *Aetznatron*, G.

Formula NaHO. Molecular weight 40.

Soda should be kept in well-stopped bottles made of hard glass.

Preparation.—Take of solution of soda 2 pints. Boil down rapidly in a silver or clean iron vessel until there remains a fluid of oily consistence, a drop of which, when removed on a warmed glass rod, solidifies on cooling. Pour the fluid on a clean silver or iron plate or into moulds, and as soon as it has solidified break it in pieces and preserve it in stoppered green-glass bottles.—*Br.*

The preparation of solution of soda is described on page 922. On evaporating it, hydrate of sodium is left, and this is either moulded into thin cylinders or congealed on a plate or tile. Vessels of porcelain, glass, etc. are readily corroded; soda must therefore be prepared in clean iron or silver vessels. For uses in the arts caustic soda is extensively prepared from the same raw material from which sodium carbonate and bicarbonate are made; baryta and strontia have been used in the place of lime, and various complicated processes have been applied in the manufacture. Soda was first obtained by Stahl (1702), but its preparation from the sulphate and chloride was first described by Duhamel (1736).

Properties.—Caustic soda is white (or grayish-white, *Br.*), hard, opaque, inodorous, very alkaline in reaction, strongly corrosive, and of an intensely acrid and caustic taste. It is usually seen in irregular fragments having a fibrous appearance, or in cylindrical sticks which are crystalline upon a fresh fracture. On exposure to the atmosphere it absorbs water and is liquefied, and subsequently it solidifies again and becomes efflorescent, in consequence of the absorption of carbonic acid and the crystallization and efflorescence of sodium carbonate. According to Osann, 1 part of water dissolves at 18° C. (64.4° F.) 0.6 parts of soda, while boiling water takes up 1½ parts; such concentrated solutions, when exposed to a temperature of - 10° C. (14° F.) or less, separate thick tabular crystals of the hydrate, (NaHO)₇·7H₂O, which melt again above 6° C. (42.8° F.). Soda is also freely soluble in alcohol. The strong aqueous solution of soda dropped into test solution of tartaric acid, so that the latter remains in excess, deposits acicular crystals of acid sodium tartrate, which are dissolved on the addition of more soda or of water. Anhydrous soda melts at a full red heat, but the hydrate fuses at a lower heat to a colorless oily liquid, and at a strong red heat is slowly volatilized. If held in a non-luminous flame an intense yellow color is imparted to the latter.

Tests.—Alcohol dissolves caustic soda, but leaves most of the salts behind which are likely to be present. "If soda be dissolved in 2 parts of water and the solution dropped into alcohol, not more than a slight precipitate should make its appearance (limit of silica or of carbonate). Dropped into an acid, it should not produce more than a faint effervescence of isolated bubbles (limit of carbonate)."—*U. S.* When dissolved in water, the solution should be colorless (organic matter), and after acidulating with nitric acid merely a slight cloudiness should be produced with nitrate of silver or chloride of barium (limit of chloride and sulphate). 40 grains of soda dissolved in water should leave scarcely any sediment, and require for neutralization about 900 grain-measures of the volumetric solution of oxalic acid (*Br.*), indicating the presence of about 90 per cent. of NaHO. The U. S. P. requires not less than 90 per cent. of this hydrate, so that 2 Gm. of soda are neutralized by at least 45 Cem. of the volumetric solution of oxalic acid. Commercial soda sometimes contains alumina, which is soluble in water, but insoluble in alcohol; on treating with excess of ammonium chloride, it will separate as a white gelatinous precipi-

tate, which is dissolved again by excess of hydrochloric acid. Sulphide, if present, will cause the precipitate with lead salt to be more or less brown, instead of white, and cyanide will produce Prussian blue on adding to the solution a little ferrous and ferric salt and acidulating with hydrochloric acid.

Composition.—The formula of soda is NaHO . When pure it contains 22.5 per cent. H_2O and 77.5 per cent. Na_2O . Crystallized hydrates of sodium are also known containing $3\frac{1}{2}$ and $1\frac{1}{2}$ molecules of water, and respectively 30.1 and 46.3 per cent. Na_2O .

Off. Prep.—Liquor sodæ, *U. S.*, *Br.*

Metallic Sodium and Salts.—SODIUM, *s. Natrium*, was isolated by H. Davy (1807), and is prepared on a large scale by heating in an iron retort an intimate mixture of 30 parts of exsiccated carbonate of sodium, 13 parts of coal, and 5 parts of chalk; the reduction takes place at a lower temperature than is required for the isolation of potassium. Sodium is silver-gray, has a strong metallic lustre, and at ordinary temperatures may be cut like wax. It melts near 90°C . (194°F .), and at a red heat volatilizes. Its density is .97. In contact with air it is oxidized, and therefore requires to be kept under petroleum naphtha, or should be protected by being coated with a layer of paraffin, as proposed by Wagner (1863). It unites with oxygen, forming *monoxide*, Na_2O , and *dioxide*, Na_2O_2 . It was admitted in the *Br. P.* for preparing solution of sodium ethylate (page 923).

SALTS OF SODIUM. Soda is nearly as strong a base as potassa, and yields salts which are colorless unless the acid is colored, have a neutral reaction except those with weak acids, and are not volatilized at a low red heat, and somewhat less readily than potassium salts at a higher temperature. They impart to flame an intense yellow color, which is not visible if examined through a blue glass. They are mostly readily soluble in water, and these solutions yield with hydrofluosilicic acid gelatinous precipitates, and, when neutral or alkaline, afford with metantimoniate of potassium white crystalline precipitates. Similar precipitates are obtained with most other metallic salts, which must therefore be removed by the proper reagents, with the exception of those of potassium, before the test for sodium is applied.

Medical Action and Uses.—The chemical and toxic actions of soda are the same as those of potassa. (For a detailed description, see Lesser, *Virchow's Archiv*, lxxxiii. 224.) Caustic soda, although less deliquescent, and therefore more manageable, than caustic potassa, is not so generally employed as an escharotic. It would appear probable also that as it is more assimilable, and therefore less apt than potassa to be immediately secreted with the urine, it should be better adapted than the latter for all cases in which it is desired to render the blood and the secretions more alkaline. But in either case the bicarbonates are preferable to the alkalies themselves. Soda is administered in the official solution and in *doses* of from 10 to 20 minims (Gm. 0.60–1.30).

SODÆ CITRO-TARTRAS EFFERVESCENS, *Br.*—EFFERVESCENT CITRO-TARTRATE OF SODA.

Sodii citro-tartras effervescens, Br.—Effervescent citro-tartrate of sodium.

Preparation.—Mix thoroughly the following powders: Bicarbonate of Sodium, 17 ounces; Tartaric Acid, 9 ounces; Citric Acid, 6 ounces; and Refined Sugar, 5 ounces. Mix the powders thoroughly, place them in a dish or pan of suitable form heated to between 200° and 220°F ., and when the particles of the powder begin to aggregate stir them assiduously until they assume a granular form; then by means of suitable sieves separate the granules of uniform and most convenient size, and preserve the preparation in well-closed bottles.—*Br.*

For the preparation of granular powders, see page 1254. If kept dry, this citro-tartrate is preferable to a mixture of the powdered ingredients, which soon undergoes decomposition. Thrown into water, it dissolves with brisk effervescence.

Medical Action and Uses.—This preparation is equivalent in its action to the effervescing draught, and may be prescribed with advantage to moderate fever, promote perspiration, and diminish the acidity of the urine and other secretions. It is conveniently employed in *fevers* and *inflammations*, and especially in acute articular *rheumatism*. *Dose*, from 60 to 120 grains (Gm. 4–8) in several fluidounces of water.

SODII ACETAS, *U. S.*—ACETATE OF SODIUM.

Sodæ acetat, *Br.* 1867; *Natrium aceticum*, *P. G.*; *Acetas sodicus (natricus)*; *Terra foliata tartari crystallisata*.—*Acetate of soda*, *E.*; *Acétate de soude*, *Fr.*; *Natriumacetat*, *Essigsäures Natron*, *G.*

Formula $\text{NaC}_2\text{H}_3\text{O}_2 \cdot 3\text{H}_2\text{O}$. Molecular weight 136.

Preparation.—Acetate of sodium was first prepared by Duhamel (1736) and by J. F. Meyer (1767), and was made by Doerffurt (1793) from sugar of lead by decom-

posing it with carbonate and sulphate of sodium. It may be obtained by neutralizing acetic acid or by decomposing acetate of lead with carbonate of sodium, in the latter case filtering from the insoluble carbonate of lead and evaporating the clear liquids to crystallization. The salt is, however, manufactured on a large scale in the United States in the process for purifying acetic acid from wood-vinegar. (See p. 20.)

Properties.—This salt crystallizes in colorless, transparent, monoclinic prisms which are odorless and slightly alkaline, have a bitterish saline taste and are somewhat efflorescent on exposure, falling in dry air to a white powder. The crystals melt at 75°C . (167°F .), and this liquid boils at 123°C . (253.4°F .) (Jeannel, 1866), and parts with the water of crystallization, the loss amounting to 39.7 per cent. The anhydrous salt, when exposed to the air, absorbs again the water of crystallization, and when carefully heated to about 315°C . (599°F .) (Schaffgotsch, 1857) melts to a colorless liquid, and on cooling congeals to a crystalline mass. At a higher heat the salt becomes black, and is decomposed, yielding acetone and volatile empyreumatic products, and leaving black sodium carbonate behind, which on being heated to redness in the air becomes white.

FIG. 280.

Crystal of Sodium Acetate.

The crystallized salt, according to Osann, dissolves at 6°C . (43°F .) in 3.9 parts, at 37°C . (98.6°F .) in 2.4 parts, and at 48°C . (118.4°F .) in 1.7 parts, of water. Solutions made with boiling water contain anhydrous salt, and remain for a time supersaturated. The salt is stated to be soluble in 1.4 parts (*P. G.*), in 3 parts (*U. S.*) of water at 15°C . (59°F .); according to Osann, 3.5 parts are necessary. According to Gerardin (1865), at 18°C . (64.4°F .) the crystallized salt dissolves in 47.6 parts of alcohol sp. gr. .8322, in 25.7 parts of alcohol sp. gr. .8464, and in 6.8 parts of alcohol sp. gr. .9088, and, according to Doebereiner, in 2.1 parts of boiling strong alcohol. The salt is insoluble in ether. Sulphuric acid liberates from it acetic acid, and its aqueous solution becomes deep-red with ferric salts, and on boiling yields a brown-red precipitate.

Tests.—Dissolved in 50 parts (20 parts, *P. G.*) of distilled water, the solution should not be rendered turbid or precipitated by sulphuretted hydrogen, sulphide of ammonium, carbonate of sodium, oxalate of ammonium, chloride of barium, or nitrate of silver (absence of metals, calcium, sulphate, and chloride); the U. S. P. permits the presence of traces of sulphate, chloride, and calcium. A concentrated solution of sodium acetate yields with nitrate of silver a crystalline precipitate of acetate of silver. Carbonate, if present, is detected by the effervescence produced by the salt when thrown into a diluted acid or on adding hydrochloric or nitric acid to its aqueous solution; the latter, acidulated as indicated, when evaporated to dryness should leave a residue which is entirely soluble in water (silica). "Fragments of the salt, when sprinkled upon colorless concentrated sulphuric acid, should not impart to it any color (absence of organic impurities). If 3.4 Gm. of acetate of sodium be ignited until gases cease to be evolved, the alkaline residue should require for complete neutralization 25 Ccm. of the volumetric solution of oxalic acid (corresponding to 100 per cent. of pure acetate of sodium)."—*U. S.*

Pharmaceutical Uses.—Acetate of sodium is employed in preparing acetic acid, acetic ethers, and other compounds.

Medical Action and Uses.—Acetate of sodium resembles acetate of potassium in its action, but is milder, less apt to derange the digestion, and more efficient as a diuretic. Its dose is from 15 to 40 grains (Gm. 1–3) in a large quantity of water as a diuretic. In doses of a drachm (Gm. 4) or more it is apt to be laxative.

SODII ARSENIAS, *U. S.*, *Br.*—ARSENATE OF SODIUM.

Sodæ arsenias, *Br.*; *Natrium arsenicum*, *Arsenias natriicus* (*sodicus*).—*Arsenate* (*arsenate*) of soda, *E.*; *Arséniate de soude*, *Fr.*; *Natriumarsenat*, *Arsensaures Natron*, *G.*

Formula $\text{Na}_2\text{HAsO}_4 \cdot 7\text{H}_2\text{O}$. Molecular weight 311.9.

Preparation.—Take of Arsenious Acid 10 ounces; Nitrate of Sodium $8\frac{1}{2}$ ounces; Dried Carbonate of Sodium $5\frac{1}{2}$ ounces; Boiling Distilled Water 35 ounces. Reduce the dry ingredients separately to fine powder and mix them thoroughly in a porcelain mortar. Put the mixture into a large clay crucible and cover it with the lid. Expose to a full red heat till all effervescence has ceased and complete fusion has taken place. Pour out the fused salt on a clean flagstone, and as soon as it has solidified, and while it is still warm, put it into the boiling water, stirring diligently. When the salt has dissolved filter

the solution through paper and set it aside to crystallize. Drain the crystals, and, having dried them rapidly on filtering-paper, enclose them in stoppered bottles.—*Br.*

On fusing arsenious acid in the proper proportions with carbonate and nitrate of sodium, carbonic acid gas, CO_2 , and nitrous anhydride, N_2O_3 , are given off, and the residue is converted into pyroarsenate of sodium, as will be seen from the equation $\text{As}_2\text{O}_3 + 2\text{NaNO}_3 + \text{Na}_2\text{CO}_3 = \text{Na}_4\text{As}_2\text{O}_7 + \text{N}_2\text{O}_3 + \text{CO}_2$. The pyroarsenate, on being dissolved in water, is converted into orthoarsenate by combining with water; $\text{Na}_4\text{As}_2\text{O}_7 + \text{H}_2\text{O}$ yields $2\text{Na}_2\text{HAsO}_4$, and this salt crystallizes with $7\text{H}_2\text{O}$. The carbonate may be conveniently replaced by an equivalent quantity of solution of caustic soda, in which the arsenious acid may be dissolved, and the residue left on evaporation to dryness should then be oxidized by fusion with sodium nitrate; all danger of expelling arsenic by injudicious heating will then be avoided. The same salt is also obtained on oxidizing arsenious to arsenic acid by means of hot nitric acid, dissolving the dry residue in hot water, and adding sodium carbonate as long as effervescence is produced.

Properties.—Arsenate of sodium crystallizes in colorless, transparent, inodorous prisms having a faint alkaline taste, and which usually contain $7\text{H}_2\text{O}$ or 40.4 per cent.; when obtained at a low temperature they contain $12\text{H}_2\text{O}$ or 53.7 per cent. The officinal salt is slightly deliquescent in a moist atmosphere, but in dry air it effloresces and loses $5\text{H}_2\text{O} = 28.8$, the white powder which is finally left having the composition $\text{Na}_2\text{HAsO}_4 \cdot 2\text{H}_2\text{O}$ and containing 16.2 per cent. of water of crystallization, which is given off near 148°C . (299.4°F). The salt is soluble at 15°C . in 4 parts of water, is slightly soluble in cold alcohol, and is freely soluble in boiling water and in 60 parts of boiling alcohol. The aqueous solution has a slight alkaline reaction, and yields white precipitates with the soluble salts of barium, calcium, zinc, iron, and lead, and a brownish-red precipitate with nitrate of silver, all these precipitates being soluble in nitric acid, and that with ferric salt turning red by heat. Sulphuretted hydrogen produces in the cold slowly, but rapidly on being acidulated and heated, a yellow precipitate, which is completely soluble in sulphhydrate of ammonium. When heated upon charcoal before the blowpipe the salt gives off an alliaceous odor.

FIG. 281.

Crystal of Sodium Arseniate.

Tests.—The cold aqueous solution of the salt, acidulated with hydrochloric acid, should not at once produce a yellow precipitate or assume a yellow color on the addition of solution of hydrosulphuric acid (absence of arsenite).—*U. S.* An aqueous solution of 12.4 grains of anhydrous arseniate of sodium, acidulated with acetic acid, requires not less than 34 grains of acetate of lead for complete precipitation.—*Br.* This test is intended to show the absence of notable quantities of other salts.

Off. Prep.—Ferri arsenias, *Br.*; Liquor sod. arseniatis, *U. S., Br.*

Other Arseniates of Sodium.—If an excess of carbonate of sodium is used in the formula given above, the aqueous solution will contain *trisodic arseniate*, and yield crystals having a stronger alkaline reaction and the composition $\text{Na}_3\text{AsO}_4 \cdot 12\text{H}_2\text{O}$. With an excess of arsenic acid crystals of *monosodic arseniate*, $\text{NaH}_2\text{AsO}_4 \cdot \text{H}_2\text{O}$, may be obtained.

Medical Action and Uses.—Arsenate of sodium is said to be less apt than arseniate of potassium to produce the phenomena of arsenical poisoning, whether locally upon the stomach or through the blood, in the eyelids, conjunctivæ, etc. It might be suspected that the difference, if real, would indicate that it is less efficient. The fact, however, is declared to be otherwise. This preparation is seldom used, and then in the form of the officinal solution. 1 part dissolved in 30 parts of water is made use of to saturate unglazed linen paper, from which the so-called anti-asthmatic cigars are prepared. The dose of the arseniate is from $\frac{1}{20}$ to $\frac{1}{2}$ grain (Gm. 0.003—0.008).

SODII BENZOAS, *U. S.*—BENZOATE OF SODIUM.

Natrium benzoicum, P. G.; *Benzoas sodicus*.—*Benzoate de soude*, Fr.; *Natriumbenzoat*, *Benzoesaures Natron*, G.

Formula $\text{NaC}_6\text{H}_5\text{O}_2 \cdot \text{H}_2\text{O}$. Molecular weight 162 (anhydrous $\text{NaC}_6\text{H}_5\text{O}_2 = 144$).

Preparation.—Add to 10 parts of benzoic acid suspended in 20 parts of hot water, gradually, 7 parts of sodium bicarbonate; after the evolution of carbonic acid gas has

ceased, neutralize the liquid exactly by the addition of a little benzoic acid, or if necessary with sodium bicarbonate; filter, and evaporate with frequent stirring until the residue weighs between $13\frac{1}{2}$ and 14 parts. As the salt separates it creeps up on the sides of the dish, and should therefore be frequently scraped off and returned to the liquid portion. When sufficiently concentrated the mass is stirred until cold, when the remaining water will evaporate. The yield is $13\frac{1}{2}$ parts. This salt being very efflorescent, the German Pharmacopœia directs it to be made anhydrous, for which purpose the above solution is evaporated to dryness, when the yield is $11\frac{1}{2}$ parts. If prepared with acid sublimed from benzoïn, the solution of the salt has a brown color and the dry salt is brownish or gray.

Properties.—Benzoate of sodium is described as being a "white, semi-crystalline, or amorphous powder, efflorescent on exposure to air, odorless or having a faint odor of benzoïn, of a sweetly-astringent taste free from bitterness, and having a neutral reaction; soluble in 1.8 parts of water and in 45 parts of alcohol at 15° C. (59° F.), in 1.3 parts of boiling water, and in 20 parts of boiling alcohol. When heated the salt melts, emits vapors having the odor of benzoic acid, then chars, and finally leaves a blackened residue of an alkaline reaction which imparts to a non-luminous flame an intense yellow color, not appearing more than transiently red when observed through a blue glass. On mixing an aqueous solution of the salt with a solution of ferric sulphate previously diluted with water, a flesh-colored precipitate is produced."—*U. S.* "The anhydrous salt is white, amorphous, and soluble in 1.5 parts of water and less soluble in alcohol. A solution of the salt in 10 parts of water has a faint acid reaction, and on the addition of hydrochloric acid yields a magma containing white crystals (of benzoic acid) which are soluble in ether."—*P. G.* According to Hager, the anhydrous salt dissolves in 13.5 parts of 90 per cent. alcohol, in 4.5 parts of 60 per cent. alcohol, in 15 parts of glycerin, and is insoluble in ether, chloroform, and volatile oils; when heated, the salt becomes brown, and afterward melts near 450° C. (842° F.) to a dark-brown mass, which, ignited, burns for a short time only.

Tests.—"If the benzoic acid be separated from the salt by precipitating it with diluted nitric acid and thoroughly washed, it should respond to the tests of purity mentioned under *ACIDUM BENZOICUM*."—*U. S.* Besides this test of identity, the following tests of purity may be mentioned: "A solution of the salt in 20 parts of water should not be rendered turbid by barium nitrate (sulphate), and, after acidulating with nitric acid and adding alcohol until the crystals of benzoic acid have been redissolved, the addition of silver nitrate should not produce a precipitate (chloride)."—*P. G.* An opalescence with the last test is permitted. The solution of the salt in 40 parts of water rendered alkaline by lime-water should not give a white precipitate (carbonate, tartrate).

Medical Action and Uses.—In 1841, Ure observed that benzoic acid or an alkaline benzoate caused the uric acid to be replaced by hippuric acid in the urine, so that when taken internally they tended to prevent the formation of uric-acid gravel. Practically, these agents have been found useful in gout and rheumatism and the various ailments dependent upon either affection. In 1879, Salkowski showed that sodium benzoate very largely increases the secretion of nitrogenous and sulphurous compounds with the urine, and drew the conclusion that, while it should be useful in all diseases in which the blood is overcharged with effete matters, it must be injurious in all wasting disorders (*Virchow's Archiv*, lxxviii, 530). In 1879 there was published in a Vienna medical journal a statement that the inhalation of benzoate of sodium was capable of curing tubercular phthisis even after cavities had formed, but not long afterward experiments were made by other physicians, who declared that "they failed to yield the slightest favorable result or a trace of even the most trifling diminution of dangerous symptoms" (*Times and Gaz.*, Nov. 1879, pp. 585, 643). Before another year the medicine had been put to the clinical test in Berlin also, and found to be useless in phthisis (*Ibid.*, Jan. 1880, p. 94). One or two physicians stated that the inhalation had an anæsthetic action upon the throat, and was, under certain circumstances, not without utility.

Salkowski, Fleck, and Buchholtz discovered that sodium benzoate prevents the development of bacteria in putrescible liquids, and Graham Brown (*Arch. f. Pathol. und Pharm.*, viii, 151) found that diphtheritic fluids lose their contagious quality more speedily in a solution of benzoate of sodium than in one of salicylate of sodium or muriate of quinine. Letzerich declared that in his hands no other remedy had produced such rapid and lasting effects in *diphtheria*. In patients under the age of three years he prescribed 120 grains a day; between the third and seventh year the daily dose was from 120 to 180 grains; for children more than seven years old, 150 to 240 grains; and for adults, 150 to

360 grains. Moreover, the exudation was treated with insufflations of the powdered benzoate every three hours or less frequently, according to circumstances, or in older persons gargles were used containing the salt (*Boston Med. and Surg. Jour.*, July, 1879, p. 88). In opposition to the favorable results just referred to, we find that in Vienna the salt was not successful (*Amer. Jour. of Med. Sci.*, Jan. 1880, p. 254). Various other physicians, including Klebs and Kien, reported favorably of this treatment, while others, even in Germany, were unable to see its advantages, and outside of that country it has not found acceptance. It is needless to refer particularly to the curative virtues attributed to it in acute rheumatism, puerperal fever, pneumonia, whooping cough, etc. Whatever they may have appeared to those who promoted its use, they have not prevented the medicine from quite fading out of view.

SODII BICARBONAS, U. S., Br.—BICARBONATE OF SODIUM.

Sodæ bicarbonas, Br.; *Natrium bicarbonicum*, P. G.; *Natrium carbonicum acidulum*, *Bicarbonas sodicus*.—*Bicarbonate of soda*, *Sodium hydrocarbonate*, E.; *Bicarbonate de soude*, *Sel digestif de Vichy*, Fr.; *Natriumbicarbonat*, *Doppeltkohlensaures Natron*, G.

Formula NaHCO_3 . Molecular weight 84.

Bicarbonate of sodium should be kept in well-dried stoppered bottles.

Preparation.—Take of Carbonate of Soda 2 pounds; Dried Carbonate of Soda 3 pounds; White Marble, in fragments, 4 pounds; Hydrochloric Acid 1 gallon; Water 2 gallons; Distilled Water a sufficiency. Fill with the water a tubulated glass bottle having a few small holes drilled in the bottom; connect the tubulure tightly by a bent tube and corks with an empty two-necked bottle, and connect this with another bottle filled with the carbonates of soda well triturated together, and let the tube be long enough to reach the bottom of the bottle. Before fixing the cork in the bottle containing the carbonate of soda partially immerse the bottle containing the marble in the hydrochloric acid, previously diluted with the water and placed in any convenient vessel. When the whole apparatus is filled with carbonic acid gas fix in tightly the cork of the bottle containing the carbonate of soda, and let the action go on until the gas ceases to be absorbed. Pour upon the damp salt which is formed half its weight of cold distilled water, and shake it occasionally during the course of half an hour; then drain the undissolved portion, and dry it by exposure to the air on filtering-paper placed on porous bricks.—Br., 1867.

This salt is rarely if ever prepared by the pharmacist, but is manufactured on the large scale, one of the processes being described above. Bicarbonate of sodium does not contain any water of crystallization; a portion of the carbonate is therefore used in the exsiccated state, and another portion in crystals, which, if used in the proportion given above, contain more than sufficient water for the conversion of all the carbonate used into bicarbonate. This is produced according to the equation $\text{Na}_2\text{CO}_3 + \text{CO}_2 + \text{H}_2\text{O} = 2\text{NaHCO}_3$, and the excess of water removed by draining and exposure to the air. In the United States the process of Dr. F. R. Smith (1830) is employed by some manufacturers. Crystallized carbonate of sodium is placed in a chamber arranged in such a manner that water may be drained off; carbonic acid gas is then conducted into the chamber, and, combining with the salt, forms bicarbonate, while the water is liberated and is carried off to prevent its action as a solvent. By this arrangement the crystalline structure of the carbonate is usually not disturbed, except that the crystals lose their transparency and become opaque in proportion as the carbonate is converted into bicarbonate, and are porous and friable.

The same salt is also obtained in Solvay's process for soda: a concentrated solution of sodium chloride is mixed with ammonia, and the liquid saturated with carbonic acid gas under a pressure of about two atmospheres, when sodium bicarbonate is deposited and ammonium chloride remains in solution.

It is obviously not essential that the carbonic acid needed in this operation should be generated from marble; the same gas is largely produced in establishments where saccharine substances are undergoing fermentation, and is obtained as a waste product in many chemical operations. In some manufactories the products of combustion of the fuel used for heating steam-boilers are deprived of their impurities by washing, and subsequently utilized for saturating, at least in part, the carbonate of sodium with carbonic acid. Large quantities of this salt are manufactured in the United States, and its importation has decreased from nearly 7,000,000 pounds in 1875 to about 2,000,000 pounds annually; in 1881 it was 1,195,851 pounds.

Bicarbonate of sodium as obtained by the above processes is recognized by the United States Pharmacopœia as *Sodii bicarbonas venalis*, or *commercial bicarbonate of sodium*. It often contains carbonate of sodium, and sometimes other impurities, from which it should be freed before it is used for medicinal purposes. A suitable process is the one given by the U. S. P. 1870, modified so as to yield a product of the purity required by the present Pharmacopœia.

Purification.—Introduce 4 pounds of commercial bicarbonate of sodium gradually into a suitable conical glass percolator, cover it with a piece of wet muslin, and pour 6 pints of water upon it. When the liquid has ceased to drop, or when the washings cease to give a brown-red precipitate with a solution of mercuric chloride, remove the bicarbonate of sodium from the percolator, and dry it on bibulous paper or upon porous tiles in a cool place.

Bicarbonate of sodium is far less readily soluble in cold distilled water than the impurities which are usually present, and in percolating water slowly through it these foreign compounds, consisting mainly of carbonate and of traces of sulphate and chloride of sodium, are dissolved, together with a portion of the bicarbonate. The percolate may be utilized, after boiling for a short time, as a solution of carbonate of sodium. In the presence of water, however, the salt slowly parts with a portion of its carbonic acid, and more rapidly on a strong agitation and at an elevated temperature. While by this process the salt may be obtained of pharmacopœial purity as long as it is contained in the percolator, its removal from the apparatus and its exposure during drying are likely to occasion a further loss of the acid. It is therefore better to select a commercial salt which is otherwise pure, and keep it in thin layers in an atmosphere of carbonic gas until it answers to the rigid requirements of the Pharmacopœia.

Properties.—*Commercial bicarbonate of sodium* is a white inodorous powder, has a mildly saline not unpleasant and scarcely alkaline taste, and is of a slight alkaline reaction. It remains unaltered in a dry atmosphere at ordinary temperatures. It is insoluble in alcohol and ether, and requires at 15° C. (59° F.) 12 parts (*U. S.*), 13.8 parts (*P. G.*), of water. According to Poggiale, 100 parts of water dissolve at 10° C. (50° F.) 8.88, at 20° C. (68° F.) 9.84, and at 60° C. (140° F.) 13.68, parts of sodium bicarbonate; it dissolves in much less hot water, carbonic acid gas being given off. A similar decomposition takes place on concentrating its solution over sulphuric acid or on keeping the salt under water or in contact with moist air. It is also soluble in glycerin without change, but in the presence of borax carbonic acid gas is given off and sodium carbonate remains behind; a mixture of bicarbonate and borate of sodium is not decomposed by cold water. When heated to about 70° C. (158° F.) it begins to lose carbonic acid gas and water, the loss increasing with the temperature, so that at about 120° C. (248° F.) a salt of the composition $\text{Na}_2\text{H}_2(\text{CO}_3)_3$ is left, and above 450° C. (842° F.) Na_2CO_3 is obtained, the total loss being 36.9 per cent. The salt imparts to a non-luminous flame an intense yellow color, which on being examined through a blue glass does not, or only transiently, appear red. It dissolves with brisk effervescence in diluted acids, forming solutions in which chloride of platinum causes no precipitate. If the salt is treated with a small quantity of water, insufficient for solution, the liquid frequently reacts in the cold with a solution of sulphate of magnesium, producing a white precipitate, and causes with a solution of corrosive sublimate a dark brown-red precipitate, both reactions being due to carbonate of sodium, which is usually present in small amount.

Pure bicarbonate of sodium has the same appearance as the commercial article, but differs from it in the absence of those reactions which are occasioned by the impurities, and in the somewhat larger amount of carbonic acid gas which it yields.

Composition.—The formula of bicarbonate of sodium given above represents 36.90 per cent. Na_2O , 52.38 per cent. CO_2 , and 10.72 per cent. H_2O .

Tests.—A 1 per cent. solution of the salt, supersaturated with nitric acid, should yield at most only a slight opalescence with test solution of nitrate of silver (limit of chloride) or chloride of barium (limit of sulphate).—*U. S.* The same test is given by the *P. G.*, but a 5 per cent. solution is used, and the opalescence is required not to make its appearance, the first in 10 minutes, and the second in 2 minutes; the test of the *U. S. P.* is more in accordance with obtainable results. "On heating a small quantity of the salt with solution of soda no ammoniacal vapor should be given off. If 2 Gm. of the salt are dissolved, with very gentle agitation, in 30 Cem. (left in contact for 10 minutes with 15 Cem., *P. G.*) of cold water, and the solution added to a cold solution of 0.3 Gm. of mercuric chloride in 6 Cem. of water, only a white cloud, but neither a red (red-brown, *P. G.*) precipitate nor a red (red-brown, *P. G.*) color should make its appearance within

three minutes (5 minutes, *P. G.*) (absence of more than about 3 per cent. of carbonate).”—*U. S. P. G.* To avoid loss of carbonic acid gas, agitation should be avoided as much as possible, and should be very gentle; it is unnecessary to dissolve the bicarbonate completely in the water, since monocarbonate and sesquicarbonate of sodium are more readily soluble in water, and therefore accumulate in a solution made with a quantity of water insufficient for completely dissolving the salt. Hager modifies this test by diluting the mercuric solution with the water directed above and pouring this liquid upon the powder, which in the presence of carbonate acquires a yellow or red-brown color. “The solution of the salt acidulated with acetic acid should not be colored or precipitated by hydrosulphuric acid (metals).”—*P. G.* “To neutralize 4.2 Gm. of bicarbonate of sodium should require not less than 49.5 Ccm. of the volumetric solution of oxalic acid (corresponding to at least 99 per cent. of bicarbonate of sodium of the required degree of purity).”—*U. S.* This test is of no value unless the absence of a notable proportion of carbonate of sodium has been proved.

The pharmacopœial tests for the purity of *commercial bicarbonate of sodium* are as follows: “A 1 per cent. aqueous solution of the salt, acidulated with nitric acid, should not yield an immediate precipitate with test solution of nitrate of silver (limit of chloride) or of chloride of barium (limit of sulphate). If a portion of the salt be agitated with a quantity of water insufficient to dissolve it, the cold filtrate should not yield more than a slight precipitate with a concentrated solution of sulphate of magnesium (limit of carbonate). To neutralize 4.2 Gm. of the salt should require not less than 47.5 Ccm. of the volumetric solution of oxalic acid (corresponding to at least 95 per cent. of pure bicarbonate of sodium).”—*U. S.* Sodium carbonate, if present in small quantity, is not indicated by a cold solution of magnesium sulphate, but the test is sufficiently delicate for commercial bicarbonate. Minute quantities of carbonate are shown by solution of corrosive sublimate, which produces a brown-red precipitate of mercuric oxychloride. A mixture of calomel and pure sodium bicarbonate moistened with cold water remains white, but will assume a more or less deep-gray color in the course of a few hours, in proportion to the amount of carbonate of sodium present.

Physiological Action.—Bicarbonate of sodium is much less apt than the carbonate of the same base or than the carbonates of potassium to derange the stomach, because, it may be, that it belongs to the natural constituents of the body, and is not so promptly eliminated with the urine. This statement has been illustrated by the comparative results of injecting into the veins of animals sodium and potassium carbonates. The latter occasion sudden death, while the former produce no ill effects whatever. The protracted administration of carbonate of sodium gives rise to symptoms which will be pointed out under that article. They are, to a greater or less degree, observed when the system is saturated with the bicarbonate. Although, when taken moderately and for a short time, no ill effects are produced, and although in many cases it is habitually used without sensible injury, it nevertheless tends to augment the acid secretions of the stomach and to perpetuate the evil it was designed to cure. It probably tends to diminish the richness of the blood, and hence to impair nutrition. According to Rutherford and Vignal, it does not appreciably affect the biliary secretion. If it is taken by persons who lead a sedentary life, and in whom there is usually a predominance of acids in the gastric and renal secretions, it may be less injurious than when active and laborious pursuits restrain the formation and accumulation of acids. For the same reason, probably, a very large amount of bicarbonate of sodium may be used, not only without injury, but with conspicuous advantage, in diseases distinguished by an excess of acid in the humors, as in inflammation, gout, acid gravel, rheumatism, and diabetes; while it uniformly aggravates affections in which the crasis of the blood is impaired, as in the so-called putrid fevers and chronic affections attended with impoverishment of the blood, as albuminuria, anæmia, scurvy, etc. It is stated that the eminent chemist Thénard produced in himself a real alkaline cachexia by continuing for several months to take bicarbonate of sodium in the daily dose of nearly an ounce. The danger of taking habitually large doses is also made very striking by their cachectic effects in Bright's disease, and by the excessive and unduly prolonged administration of Vichy waters, even in appropriate cases, such as gout, gravel, and rheumatism.

Medical Uses.—The form of *dyspepsia* in which bicarbonate of sodium is peculiarly useful is that attended with acidity of the primæ viæ, and of which the chief symptoms are sour eructation and vomiting, heartburn, flatulence, and acid liquid stools. In many

eases the disorder is exclusively gastric, as in acid dyspepsia. In not a few hypochondriac symptoms are superadded. But in all of them the bicarbonate of sodium can do no more than palliate the special symptoms due to an acid fermentation of ingesta; a radical curative treatment must be attempted by other means, of which tonic medicines and regimen are the most influential. The palliative symptomatic treatment referred to is of essential service in the case of children, in whom interference with the primary digestion leads to grave and even fatal disorders. This is especially the case when their sole aliment consists of cow's milk, and the mischief can often be mitigated by adding a small portion of the bicarbonate to each portion of their food. It is essential in all cases of acid gastric dyspepsia that the bicarbonate should be taken after, and not before, meals.

In *lithiasis* a tendency to the formation of acid sand and *gravel* may be obviated by the use of this sodium salt after every meal. But it must not be overlooked that, according to competent testimony, the potassium salt is even more efficacious; and the plausible reason is assigned for the alleged fact that the latter passes off more readily than the former by the urine, and therefore tends more to maintain this fluid in a normal if not in an alkaline state. There is some reason to believe that bicarbonate of sodium is capable of producing the solution of urinary concretions already formed. It is reported to be singularly efficient in *suppression of urine* from renal disease, and even in that form of Bright's disease of the kidney in which the cause of the obstruction of the renal tubules with casts is proved by their abundance in the urinary sediment.

In *saccharine diabetes* occurring in persons of an obese habit there is little doubt that the prolonged use of the salt under consideration is sometimes of marked benefit. It is less so when the patients are thin and of a nervous constitution. Such has been the result of observations at Vichy, Carlsbad, and other alkaline mineral springs renowned for their virtues in this affection. The same waters are celebrated for their utility in *gout*. They are especially so in the simple and regular forms of the disease occurring in persons of good constitution and not yet exhausted by repeated attacks or by the complications to which the gouty become subject. In the latter case the system is already impaired, and unable to sustain the debilitating influence of an alkaline treatment. Under such circumstances a free use of alkaline water is apt to occasion a transference of the gout to internal organs, and sometimes it has led to a fatal termination of the disease. What has been said of gout applies in many respects to *biliary calculi*, for which alkaline mineral waters have always been used. According to some, the potash salt is preferable to the soda salt, but this notion is more than doubtful.

In *acute articular rheumatism*, and notably in those cases of it in which many joints are involved, and in which there is high fever, acid sweats, and loaded urine, the bicarbonate of sodium is of inestimable benefit, provided that it be given so as to maintain a neutral condition of the urine. Its efficacy is increased when the affected joints are swathed in compresses saturated with a solution of the salt. In the treatment of recent *burns* a saturated solution of this salt has been applied, with the effect of immediately relieving the pain and producing a rapid cure. This method was first proposed by Peppercorne (1844), and again recommended in 1882 (*Practitioner*, xxviii. xv.). Excellent reports of its virtues have been made by Troiski (*Med. News*, 1881, p. 679) and Koller (*Amer. Jour. Pharm.*, June, 1880, p. 319). The part should be kept constantly wet with the solution. In the case of a burn of the second degree involving two-thirds of the face and both ears, and extending over the whole back of the neck down to between the shoulders, this result was obtained (Rogers). In 1881, Armangué and Giné treated acute *tonsillitis* by the direct application of powdered bicarbonate of sodium in the forming stage of the disease, and claimed to have prevented its development in most instances (*Practitioner*, xxviii. 448). The same treatment was subsequently used in this country by Stuver (*Med. News*, xli. 567), Skinner (*Ibid.*, xlii. 156), and Vinke (*Ibid.*, xliii. 216.) It has not yet been sufficiently tested, but it has at least the advantage of being harmless. A somewhat similar application has been made in contagious *ophthalmia* attended from the first with chemosis and granulations, as well as in chronic cases of granular conjunctivitis (*Times and Gaz.*, Oct. 1881, p. 516).

Bicarbonate of sodium may be prescribed in *doses* of from 5 to 30 grains (Gm. 0.30-2) and upward. The largest doses are required in acute rheumatism. When the doses must be large the medicine is most conveniently administered in carbonated water.

SODII BISULPHIS, U. S.—BISULPHITE OF SODIUM.

Natrium bisulfurosum, Bisulphis sodicus.—*Bisulphite de soude*, Fr.; *Natriumbisulfit*, G.
Formula NaHSO_3 . Molecular weight 104.

Preparation.—This salt is employed in the arts for bleaching, and was called *leucogene* by Chaudet, who recommended it for this purpose. It is also used as *antichlor* for neutralizing the excess of chlorine after bleaching fabrics or paper-pulp, and has been recommended for the preservation of fermentable liquids and articles of food. It is prepared by saturating a solution of sodium carbonate with sulphurous acid gas and crystallizing in a cool place. Warm concentrated solutions treated in this manner usually separate on cooling *pyrosulphite of sodium*, $\text{Na}_2\text{S}_2\text{O}_5$.

Properties.—Bisulphite of sodium is in "opaque, prismatic crystals or a crystalline or granular powder, slowly oxidized and losing sulphurous acid on exposure to air, having a faint, sulphurous odor, a disagreeable sulphurous taste, and an acid reaction; soluble in 4 parts of water and in 72 parts of alcohol at 15°C . (59°F .), in 2 parts of boiling water, and in 49 parts of boiling alcohol. When strongly heated the salt decrepitates, and is converted into sulphur and sulphate of sodium. A small fragment of the salt imparts to a non-luminous flame an intense yellow color, not appearing more than transiently red when observed through a blue glass. On adding hydrochloric acid to an aqueous solution of the salt sulphurous vapors are evolved, and the solution does not become cloudy (difference from hyposulphite)."—U. S. According to Muspratt, the salt on being heated gives off sulphur and sulphurous acid gas, the residue left being sodium sulphate. The salt being easily affected by exposure, it is difficult to keep it unaltered, even in stoppered bottles, and to preserve for it the purity required by the tests given below. Pyrosulphite of sodium resembles the pharmacopœial salt in its properties.

Tests.—"A 1 per cent. aqueous solution of the salt, acidulated with hydrochloric acid, should not yield more than a faint cloudiness with test solution of chloride of barium (limit of sulphate). If 0.26 Gm. of the salt be dissolved in 10 Ccm. of water, and a little gelatinized starch added, at least 48 Ccm. of the volumetric solution of iodine should be required before a permanent blue tint appears after stirring (corresponding to at least 96 per cent. of pure bisulphite of solution)."—U. S.

Medical Uses.—The action and uses of the bisulphite of sodium are essentially the same as those of the sulphite; it is, however, supposed to derive greater efficiency from the larger proportion of sulphurous acid in its composition. *Dose*, from 10 to 30 grains (Gm. 0.60–2).

SODII BORAS, U. S.—BORATE OF SODIUM.

Borax, Br., P. G.; *Natrium biboricum (pyroboricum), Boras sodicus.*—*Borax*, E., Fr., G.; *Borate de soude, Bauracon, Sel de Perse*, Fr.; *Natrium pyroborat*, G.
Formula $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$. Molecular weight 382.

Origin and Preparation.—It is uncertain whether borax was known to and used by the ancients, and even in the Middle Ages it was frequently confounded with other salts. The observations of Homberg (see page 37), Geoffroy (1732), and others did not lead to correct views regarding the chemical nature of borax until Baron (1747) showed that the "sedative salt" exists in it combined with soda. Borax is found native as *tincal* in Persia, Thibet, and other localities, as a saline incrustation on the shores of certain lakes, and as a crystalline deposit at the bottom of the borax lake in California. The incrustation and the deposit are continually renewed by crystallization from the lake waters as fast as the borax is removed. Tincal requires to be washed with a solution of caustic soda for effecting the removal of fatty matter with which the crystals are covered, and on being afterward recrystallized from water yields borax. Borax is also prepared from various native borates which are found in Nevada, in certain parts of South America, Europe, and Asia, and which are known as the minerals *boracite*, *borosodalcite*, *cryptomorphite*, etc. These consist of boric acid combined in varying proportions with sodium, calcium, and magnesium, and mixed with sulphates, chlorides, and silica, and yield borax on being treated with carbonate of sodium and after recrystallization from water.

Most of the borax is at present prepared from commercial crude boric acid, which is either boiled with a solution of soda, or, more generally, is fused together with calcined sodium carbonate. The Italian boric acid yields with the carbonic acid gas ammonia, which is also utilized. The fused mass is then dissolved in water, and this solution sepa-

rated from the ferric hydrate and other impurities suspended in the liquor, and evaporated sufficiently, when it is permitted to cool slowly, so that large crystals are obtained, from which the mother-liquor is rapidly withdrawn.

Previous to 1880 the importation into the United States of borax amounted to about 3500 pounds annually, but in 1880 and in 1882 it exceeded 15,000 pounds, and in 1883 over four and one-third million pounds of boric acid were imported.

Properties.—Borax forms large, colorless, monoclinic prisms, which are transparent, inodorous, have a mild sweetish, cooling, and afterward alkaline taste, and in dry air effloresce superficially and become opaque. When heated it melts in its water of crystallization, and is converted into a light white spongy mass, which at a red heat fuses,

FIG. 282.

Crystal of Borax.

and on cooling forms a transparent glass. Borax has the specific gravity 1.72, has a weak alkaline reaction, is insoluble in alcohol, but dissolves at 80° C. (176° F.) in 1 part of glycerin and at 15° C. (59° F.) in 16 parts of water. The glycerin solution imparts a green color to flame (Senier and Lowe, 1878). According to Poggiale, 100 parts of water dissolve at 10° C. (50° F.) 4.65 parts, at 20° C. (68° F.) 7.88 parts, at 30° C. (84° F.) 11.90 parts, at 40° C. (104° F.) 17.90 parts, and at 100° C. (212° F.) 201.43 parts, of crystallized borax. If a saturated solution of borax is prepared at an elevated temperature and kept at a temperature exceeding 56° C. (133° F.), borate of sodium containing 5H₂O will crystallize in octahedral crystals which are harder than borax. A cold solution of borax absorbs considerable quantities of carbonic acid and sulphuretted hydrogen, both gases being again expelled on heating and evaporating the liquid. On adding a mineral acid to a hot saturated solution of borax in water, a scaly

crystalline precipitate is obtained on cooling, the alcoholic solution of which burns with a green flame, and the acidulated aqueous solution changes the color of turmeric-paper to brown. Borax held in a non-luminous flame imparts to it an intense yellow color.

Composition.—The water of crystallization amounts to 47.12 per cent., Na₂O to 16.23, and B₂O₃ to 36.65 per cent. The crystallized and the anhydrous salt, Na₂B₄O₇, are compounds of pyroboric acid (see p. 38).

Tests.—The solution of borax should not effervesce with acids (absence of carbonate), should not be colored or precipitated by sulphuretted hydrogen (heavy metals), and should not yield any precipitate or turbidity with carbonate of sodium or of ammonium (salts of calcium, etc.), nor, if acidulated with nitric acid, with barium chloride (sulphate) or with nitrate of silver (chlorides). These tests are applied in a 2 per cent. solution, and a slight opalescence within five minutes with the two last tests is permitted by the P. G., while the U. S. P. requires that no turbidity should appear in a 1 per cent. solution. Traces of chloride are always, and of sulphate occasionally, present in good commercial borax. "191 grains of borax dissolved in 10 fluidounces of distilled water require for saturation 1000 grain-measures of the volumetric solution of oxalic acid."—*Br.*

Off. Prep.—Glycerinum boracis, Mel boracis, *Br.*

Allied Salt.—AMMONIUM BORAS.—Borate of ammonium, *E.*: Borate d'ammoniaque, *Fr.*: Borsures Ammonium, *G.* Formula 2(NH₄HB₂O₄).3H₂O. Molecular weight 264.—For preparing it, 1 part of boric acid is dissolved in 3 parts of warm ammonia-water spec. grav. .960, and the solution allowed to cool slowly. The crystals are rapidly dried between bibulous paper and preserved in a well-stopped bottle. The salt crystallizes in white or transparent octahedrons which have a strong ammoniacal odor, and on exposure are converted into an acid salt: they dissolve in 12 parts of cold water, and the solution, when heated, evolves ammonia, and on evaporation separates transparent octahedral crystals of an acid salt which has no ammoniacal odor.

Physiological Action.—In the dose of 6 drachms borax has created no unpleasant effects except a temporary sense of oppression in the stomach, or, at most, nausea and vomiting. Continued large doses produce the same consequences as the prolonged use of other salts of sodium—viz. liquefaction of the blood and scorbutic symptoms, and sometimes an impetiginous eruption on the skin. Since borax was introduced into the treatment of epilepsy, Dr. Gowers has shown that an eruption of characteristic psoriasis may result from its use. Several cases of the sort which came to his knowledge were relieved of the cutaneous affection by arsenic (*Lancet*, Sept. 24, 1881). It is largely eliminated with the urine, either unchanged, or, after decomposition, as urate of sodium. It is secreted also with the saliva. Physiological experiment does not illustrate the action

of this salt upon the uterine system, for it is only in certain special conditions of that system that its powers are manifested. According to Polli, borax is a powerful antiseptic and anti-fermentative.

Borax is well known to be hostile to the lower forms of animal life. It is a common domestic remedy for destroying cockroaches. In a solution of even less than 1 per cent. of this salt bacteria cannot be developed. In 1874 and subsequently it was found a very efficient preparation for the purposes of antiseptic surgery.

Medical Uses.—This substance is supposed to be described by Pliny under the name of *chrysocolla*; by the Arabians it was called *tankâr* (Sonthheimer). The former speaks of its drying and healing action upon wounds when applied as a powder—of its use in sore throat, and in collyria for removing opacities of the cornea, and in plasters for effacing scars. The latter allude to its cleansing and astringent virtues, to its application in caries of the teeth, etc., and to its use by goldsmiths as a flux for gold. A solution of borax (gr. xxx to fʒj) (Gm. 2 to Gm. 32) is quite efficient in diminishing and even removing *freckles*, *chloasma*, and those unseemly eruptions by which some women are annoyed at the menstrual periods. A drachm of borax in half an ounce of cold cream forms an excellent ointment for *chilblains*. As a lotion for *ringworm of the scalp* a solution has been recommended of 1 drachm of borax in 2 ounces of distilled vinegar. Borax has also been applied with good effect in *pityriasis versicolor* and for removing *opacities of the cornea*. It is used to heal *ill-conditioned ulcers*, and especially those of the mouth occurring in *ulcerative stomatitis*, and also to restore their firmness to *spongy gums*. In the last cases particularly it should be associated with honey and myrrh. Borax is less efficient in them than chlorate of potassium, but like it acts only as a local stimulant. It is of constant use for the cure of *aphthæ* of the mouth and fauces occurring in nursing children. In the first-named affections it should be finely powdered with white sugar and applied directly to the affected part. It is equally efficacious in *thrush*, which proceeds from the acid fermentation of the milk and occurs in the buccal cavity, about the anus, etc. Mixtures of borax with honey and with glycerin will answer the same purpose, but perhaps less efficiently. These, or the powder, or a simple watery solution, may be applied to aphthous sores of the *vulva* and *vagina*, to fissures of the *nipples*, and to similar lesions. It is sometimes advantageous to associate with the borax Peruvian balsam, benzoin, or some analogous agent to modify or strengthen its action. They may be incorporated in a mixture made with yolk of egg, oil of almonds, etc. A solution of borax is one of the best topical applications in *purigo pudendi*, and one of the most efficient vaginal injections for *leucorrhœa*, especially when it is due to superficial ulcers of the cervix.

In subacute *laryngitis*, especially as it occurs in children, a mixture of powdered borax with honey or syrup has been found serviceable by its stimulating action upon the adjacent pharyngeal mucous membrane. A like effect has been observed in *hoarseness* and in *aphonia* due to laryngeal congestion merely or to exhaustion of the larynx by an excessive use of the voice. The best mode of using it is to allow a piece of borax of the size of a pea gradually to dissolve in the mouth.

Very few writers upon therapeutics admit that borax stimulates the uterine system, *promoting menstruation* and *labor* and checking *hæmorrhage*. The difficulty of determining the precise value of an emmenagogue medicine is notorious, and in this case, at least as much as in others, large assertion is mixed with little proof. The power attributed to borax of exciting the gravid uterus to contraction does not appear to us susceptible of well-grounded doubt, and, while believing that it is efficacious in uterine hæmorrhage, we should find a demonstration of its value difficult.

Dr. Gowers (*Times and Gaz.*, April, 1880, p. 447) states that in some inveterate cases of *epilepsy*, in which the bromides had no effect, he tried borax without advantage sometimes, but in a certain number of instances its value was distinct. The doses were 10 or 15 grains twice or three times a day. Sometimes it occasioned gastro-intestinal disturbance, and rarely a form of dysenteric diarrhœa. A tendency, which it showed, to cause a scaly eruption has been noticed above.

The utility of solutions of borax in cases of *uric-acid gravel* is very great. Entering the urine nearly unchanged, a great part of the borax taken presents itself to the uric acid, which decomposes it, forming a soluble urate of sodium, which, with the freed boracic acid, is discharged. Borax may be given internally in the *dose* of from 5 to 30 grains (Gm. 0.30–2), in watery solution largely diluted.

BORATE OF AMMONIUM was proposed as a remedy for disorders of the *urinary secretion* attended with an excess of acid or of earthy phosphates and irritability of the bladder.

It does not, however, seem to have answered these purposes, since it has completely fallen into disuse. Yet it would seem to be nearly as well fitted for them as borate of sodium. The dose is from 10 to 20 grains (Gm. 0.60–1.30), in an abundant watery solution.

SODII BROMIDUM, *U. S., Br.*—BROMIDE OF SODIUM.

Natrium bromatum, P. G.; *Bromuretum sodicum*.—*Bromure de sodium*, Fr.; *Bromnatrum*, G.

Formula NaBr. Molecular weight 102.8.

Preparation.—Bromide of sodium may be prepared in a manner similar to bromide of potassium (see page 1210). A solution of ferrous bromide, boiled with a solution of carbonate of sodium, yields a precipitate, the filtrate from which is evaporated and crystallized.

Properties.—At a temperature of about 20° C. (68° F.) and below colorless, transparent, oblique-rhombic prisms are obtained having the composition NaBr.2H₂O (mol. weight 138.8), and when heated melt and give off the water of crystallization. But when the solution is kept at a temperature above 30° C. (86° F.), anhydrous cubes of bromide of sodium are obtained, which have a saline, somewhat alkaline, and scarcely bitterish taste, and a neutral or faint alkaline reaction. The salt is usually met with in the form of a white crystalline, inodorous powder which is permanent in dry air, and is stated to be soluble in 0.5 part of boiling water, in 11 parts of boiling alcohol (*U. S.*), and at 15° C. (59° F.) in 1.2 (*U. S.*) or 1.8 (*P. G.*) parts of water and in 13 (*U. S.*) or 5 (*P. G.*) parts of alcohol. According to Kremers (1856), 1 part of the anhydrous salt is soluble at 0° C. (32° F.) in 1.29, at 20° C. (68° F.) in 1.13, and at 100° C. (212° F.) in 0.87, parts of water, and the saturated solution boils at 121° C. (250° F.). According to Hager, the anhydrous salt is soluble in 10 parts of 90 per cent. alcohol and in 3 parts of 60 per cent. alcohol, while the hydrated salt requires 7 parts of the former and 2.25 parts of the latter for solution. The hydrated salt melts in its water of crystallization, but the anhydrous salt requires a red heat for fusion, and then volatilizes slowly without decomposition. The salt imparts to a non-luminous flame an intense yellow color, which, when observed through a blue glass, should not appear permanently red (*U. S., P. G.*). "If disulphide of carbon be poured into a solution of the salt, then chlorine-water added drop by drop, and the whole agitated, the disulphide will acquire a yellow or yellowish-brown color without a violet tint."—*U. S.* The *P. G.* employs ether for this test of identity. Hager recommends the following as simple and efficient: Pour slowly 3 Ccm. of solution of copper sulphate, containing 20 per cent. of the salt, upon 0.3 Gm. of powdered sodium bromide, which will at once become black or black-brown (potassium bromide remains white, ammonium bromide turns red-brown); on agitation a nearly clear blue or greenish-blue solution will result (a green turbid liquid indicates presence of iodide); on the further slow addition of 1 Ccm. of concentrated sulphuric acid black cupric bromide is separated. The salt differs from bromide of potassium in imparting a yellow color to flame, and in not being precipitated from its concentrated solution by a strong solution of acid tartrate of sodium.

Tests.—The pharmacopœias give nearly identical tests for alkalinity, bromate, iodide, sulphate, and chloride, as follows: "Fragments of the salt placed upon moistened (not wet) red litmus-paper should not at once turn it blue (limit of alkalinity)."—*P. G.* "If diluted sulphuric acid be dropped on a portion of the salt, the latter should not at once assume a yellow color (absence of bromate). On adding to 1 Gm. of the salt, dissolved in 20 Ccm. of water, 5 or 6 drops of test solution of nitrate of barium, no immediate cloudiness or precipitate should make its appearance (limit of sulphate). If 3 Gm. of the well-dried salt be dissolved in distilled water to 100 Ccm. (in 100 Ccm. *P. G.*) and 10 Ccm. of this solution be treated with a few drops of test solution of bichromate of potassium, and then volumetric solution of nitrate of silver be added, not more than 29.8 Ccm. (29.6 Ccm. *P. G.*) of the latter should be consumed before the red color ceases to disappear on stirring (absence of more than 3 per cent. of chloride)."—*U. S., P. G.* "If 1 Gm. of the salt be dissolved in 10 Ccm. of water, some gelatinized starch added, and then a few drops of chlorine-water be carefully poured on top, no blue zone should make its appearance at the line of contact of the two liquids (absence of iodide)."—*U. S.* "If 20 Gm. of a 5 per cent. solution of the salt be mixed with a few drops of solution of ferric chloride, and then agitated with chloroform, the latter should not acquire a violet color (iodine)."—*P. G.* 1 Gm. of the salt, when completely precipitated by nitrate

of silver, yields, if perfectly pure, 1.824 Gm. of dry bromide of silver; in the presence of sodium chloride the precipitate will weigh more.

Medical Action and Uses.—Although various theoretical considerations have been regarded as sufficient to prove the bromide of sodium preferable as a medicine to the potassium bromide, physiological experiment and clinical observation agree in teaching that sodium bromide possesses in a less degree the characteristic sedative and hypnotic properties of bromide of potassium. It has been claimed to be more eligible than the latter salt, because it does not excite an eruption of acne nor occasion hebetude of mind or body; but the latter symptom is the very index of the efficiency of the potassium salt, at least in epilepsy; and if it fails to occur under bromide of sodium, the occurrence can only be taken as a proof that the latter is inoperative in cases for which the potassic bromide is appropriate. It is given in the same *doses* as bromide of potassium. In point of fact, however, bromization of the nervous system is produced by the sodium salt when taken in large doses. Cutler has related (*Boston Med. and Surg. Jour.*, Mar. 1884, p. 248) the case of a man who took about 4 ounces of this compound in one week. Torpor, sopor, and lethargy succeeded one another; the skin was dusky and cool, the pulse and breathing slow; the urine was nearly suppressed, and reflex irritability abolished. The patient lay in a sound sleep for 18 days. Similar cases have before been observed (Schweig, *Med. Record*, xi. 841). In one of them there were "incoherency of speech and action, hallucinations of sight and hearing, delusions of various sorts, a general aspect of imbecility, and an almost entire absence of rational conduct." Yet the patient on recovery recollected perfectly many occurrences that had taken place during his period of mental darkness.

In regard to the relative value of the sodic and potassic bromides in the treatment of *epilepsy*, it would appear that the former is inferior to the latter, because it exerts less of that sedative influence on the nervous system which the mitigation of the disease requires. Dujardin-Beaumez and Voisin entirely reject the use of the sodium salt in epilepsy, and the weightiest evidence is on the same side of the question. Nevertheless, this salt should be used when the other disagrees with the patient or is contraindicated by a state of debility. There is no doubt, as already said, that its action is less depressing, that its taste is less offensive, that it does not tend to produce an acneiform eruption, and that it is not so apt to render the breath fetid. Hence it is to be preferred in all the affections, except epilepsy as a rule, in which the bromides are indicated, and especially when the patients are young or delicate persons. The practice of using the bromides to prevent *sea-sickness*, by producing a mild bromization, which has become very common since 1880, is reprobated by those who have had the best opportunity of forming a correct judgment of it as merely a mode of narcotic intoxication. In 1882 the case was published of Dr. F. R., who took an inordinate quantity of bromide of sodium (11 oz.) for the purpose referred to, and who under its influence became insane, jumped overboard, and was drowned.

Lactate of sodium has also been proposed as possessing hypnotic qualities (*London Med. Record*, Dec. 15, 1879), but none were shown among seventeen patients of Krocmer, even after very large doses of the salt had been taken. Others condemn it from its tendency to disorder the stomach and produce diarrhoea.

This medicine has been credited with antiseptic and germicide powers. Brackenridge attributed to its use the favorable issue of fifty cases of *scarlatina*. Pernot considers it a specific for *whooping cough* when the fumes given off by heating it impregnate the atmosphere breathed by the patients (*Edinb. Med. Jour.*, xxiv. 89). Dr. J. W. White (*The Mouth and the Teeth*, p. 136) says of this preparation that it is an antacid, an astringent, a sedative, a styptic, an antiseptic, and a disinfectant. As a wash for the mouth it is highly useful (when there are no local exciting mechanical causes) where the gums are spongy, swollen, and soft, and bleed at the slightest touch. It checks excessive bleeding after the extraction of teeth and relieves the subsequent soreness of the gums. It gives prompt relief to the distressing pains which sometimes follow extraction, corrects unpleasantness of the breath caused by decayed teeth or by the unhealthy secretions of the mouth, neutralizes acidity, and prevents putrefaction.

Carbolate of sodium may be given to adults in the *dose* of from 15 to 30 grains (Gm. 1-2) several times a day; the former of these doses may be administered to children without any risk.

SODII CARBONAS, *U. S., Br.*—CARBONATE OF SODIUM.

Sodæ carbonas, Br.; *Natrium carbonicum*, P. G.; *Carbonas sodicus*, *Sal sodæ depuratus*.—Pure carbonate of sodium, E.; *Carbonate de soude*, Fr.; *Natriumcarbonat*, *Kohlensaures Natron*, G.

Formula $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$. Molecular weight 286.

Origin and Preparation.—Both carbonate of sodium and of potassium were known at a very remote period, and by the ancients were called *nitron* and *nitrum*, which names were afterward applied to other salts (see page 1234). A distinction between the alkali carbonates was not made until after Duhamel's observation (1736) had shown table-salt to be the compound of an alkali, and until Marggraf (1759) had proved this alkali to differ from the vegetable alkali procured from the ashes of plants.

Carbonate of sodium exists in a large number of mineral waters, mostly, however, as bicarbonate. It is contained in the waters of certain lakes in India, Egypt, Central Africa, Mexico, and South America, and is found in the ashes of many plants growing near the seashore, such as *Salsola*, *Statice*, *Salicornia*, *Atriplex*, *Mesembryanthemum*, and others. These ashes are known in commerce as *barilla*, *salicor*, etc., the former containing nearly 30 per cent., the latter about 14 per cent., of sodium carbonate. *Kelp* and *varec*, the ashes of various marine Algae, contain much less soda, and are at present not employed for obtaining this salt. Egyptian *trona*, a native carbonate of sodium, contains both carbonate and sesquicarbonate. In Hungary and some other countries carbonate of sodium effloresces from the earth.

The most important sources of this salt are cryolite and the sulphate and chloride of sodium. *Cryolite* is a mineral found in Greenland, and consists of fluoride of sodium and aluminium. When boiled with an excess of caustic lime, insoluble fluoride and aluminate of calcium are obtained and caustic soda remains in solution; and when a mixture of cryolite and chalk is cautiously heated to redness, but not to fusion, fluoride of calcium and aluminate of sodium are produced, this last compound being soluble in water and decomposed by carbonic acid, which precipitates aluminium hydrate, retaining a little sodium carbonate, while pure carbonate of sodium remains in solution.

The production of soda directly from sodium chloride has led to numerous investigations, and as early as 1838 it was accomplished by H. Dyar and J. Hemming; but the process, and more particularly the apparatus for the successful working of it, attained greater perfection since E. Solvay began to use it in 1865 on an extensive scale. It consists in conducting, under pressure, into a cold concentrated solution of chloride of sodium, first ammonia gas and afterward carbonic acid, when bicarbonate of sodium and chloride of ammonium are formed; most of the former salt is deposited, and after having been heated to redness requires to be dissolved in water and crystallized in order to obtain carbonate of sodium. In the first part of this process the reaction takes place between bicarbonate of ammonium and chloride of sodium, but the conversion of the latter salt into bicarbonate is never complete.

Carbonate of sodium is obtained by *Leblanc's process* from sulphate of sodium, which is mixed with chalk and coal and the mixture ignited; the mass is exhausted with water and the solution concentrated, the carbonate separating from the hot liquid being removed, while fresh portions of the solution are added until the carbonate becomes too much contaminated with foreign salts, when it is calcined with charcoal and afterward recrystallized. In the first part of this process carbonate of sodium and sulphate of calcium are formed by double decomposition, and the sulphate is reduced by the coal to sulphide; but the ignited mass contains also caustic soda, sulphate and hyposulphite of sodium. The crude product obtained by evaporating the first solution to dryness is sent to market as *soda-ash*, and of this 165,502,900 pounds were imported into the United States in 1876, and in addition to this 20,074,269 pounds of carbonate of soda and 32,093,691 pounds of caustic soda. The importation of soda-ash in 1883 reached 323,726,726 pounds, and in 1882, of carbonate and caustic soda, 29,842,140 and 56,878,896 pounds, respectively. Large quantities of these compounds are also manufactured here.

Properties.—As obtained in commerce, carbonate of sodium is in large, colorless, oblique-rhombic crystals, or frequently in crystalline lumps, inodorous, and with a harsh alkaline taste and a decided alkaline reaction. On exposure it becomes white and friable from the loss of water of crystallization, and ultimately falls into a soft white powder; the amount of this loss depends upon the temperature, and is in ordinarily dry air of 12.5° C. (54.5° F.) 31 per cent., and at about 35° C. (95° F.) 56.6 per cent.; the last molecule of water is expelled below the boiling-point of water. The salt melts

between 32.5° C. (90.5° F.) and 34.5° C. (94° F.) in its water of crystallization, and after this has been expelled melts again at a red heat, at the same time parting with a portion of carbonic acid. In water heated to above the melting-point of the crystallized salt the solubility of the latter does not vary much; 1 part of it dissolves, according to Loewel (1851),

Fig. 283.

at 0°	10°	15°	20°	25°	30°	38°	104° C.,
in 4.7	2.44	1.6	1.08	0.67	0.37	0.088	0.185 parts of water.

The salt is insoluble in alcohol and ether. It effervesces strongly on the addition of an acid, and it imparts an intense yellow color to a non-luminous flame.

SODII CARBONAS VENALIS, NATRIUM CARBONICUM CRUDUM, P. G.; Sal sodæ, Soda cruda.—Sal soda, Washing soda, *E.*; Sel de soude; *Fr.*; Soda, *G.*—This is the salt generally met with in commerce. It should contain at least 32 per cent. of anhydrous sodium carbonate (*P. G.*); in other respects it resembles the pure salt. It is used for preparing the latter by recrystallizing from hot water until the crystals respond to the pharmacopœial tests of purity, and it is advisable to agitate the cooling solution, so as to obtain small crystals or a crystalline powder, which is readily freed from the mother-liquor by draining and washing with a little cold water. The pure salt should be kept in a well-stopped bottle in a cool place. 20 grains of it neutralize 9.7 grains of citric acid or 10½ grains of tartaric acid.

Crystal of Sodium Carbonate.

Tests.—Commercial carbonate of sodium contains small but variable quantities of sulphate and chloride, and its solution in water acidulated with nitric acid therefore produces precipitates with barium chloride and with nitrate of silver. Cryolite is the source of an impurity which is sometimes met with, and which consists of alumina rendered soluble in water by the soda: it is best detected by acidulating its solution in water with hydrochloric acid, heating to boiling, and then supersaturating with ammonia, when gelatinous aluminium hydrate will be precipitated. "The aqueous solution should be free from suspended or colored impurities, and, after being supersaturated with nitric acid, should not yield more than a trifling precipitate with test solution of nitrate of silver (limit of chloride) or of chloride of barium (sulphate). The aqueous solution should remain unaffected by hydrosulphuric acid, either before or after being supersaturated with hydrochloric acid (absence of metals). A solution of the salt acidified by the last-named acid, when supersaturated with ammonia and boiled, should not yield a gelatinous precipitate (alumina)." — *U. S.* With the exception of the last one, the tests of the *P. G.* are similar to those given above, and are applied in a 2 per cent. solution acidulated with acetic acid; the following delicate test for arsenic is added: Dissolve 2 Gm. of the salt in 10 Cem. of diluted sulphuric acid; add a few drops of iodine (for converting sulphurous acid, if present, into sulphuric acid), afterward zinc, and proceed in the same manner as directed for the testing of hydrochloric acid (see page 65); the paper, moistened with solution of silver nitrate, should not be colored yellow or brown in 30 minutes.

The *P. G.* requires the salt to contain 37 per cent. of anhydrous carbonate or to be nearly chemically pure. Both the *U. S. P.* and *Br. P.* limit the purity to at least 96 per cent. of pure crystallized salt, when for neutralizing 7.15 Gm. of carbonate of sodium not less than 48 Cem. of the volumetric solution of oxalic acid should be required (or for 143 grains of the salt 960 grain-measures of the solution).

Composition.—Pure crystallized carbonate of sodium contains 62.9 per cent. of water, 21.7 per cent. of Na_2O , and 15.4 per cent. of CO_2 . When boiled with a little water a salt is deposited containing only 14.5 per cent. of water = $1\text{H}_2\text{O}$. Several other salts are obtainable, which crystallize with 3, 5, and $7\text{H}_2\text{O}$. Besides the carbonate and bicarbonate of sodium, another compound of intermediate composition may be obtained; this *sesquicarbonate* requires about 7 parts of water for solution, and contains nearly 22 per cent. of water.

Pharmaceutical Uses.—Carbonate of sodium is used in preparing Aluminium hydras. *U. S.*; Antimonii oxidum, Calcii carbonas, *Br.*; Liquor sodæ, Liquor sodæ chloratæ, *U. S., Br.*; Magnes. carbonas, *Br.*; Massa ferri carbonatis, Pil. ferri comp., *U. S.*; Soda tartarata, Sodæ bicarbonas, *Br.*; Sod. carbonas exicc., *U. S., Br.*; Sod. phosphas Zinci carbonas præcipit., *Br.*

SODII CARBONAS EXSICCATUS, U. S.—DRIED CARBONATE OF SODIUM.

Sodii carbonas exsiccata, Br.; *Natrium carbonicum siccum*, P. G.—*Dried carbonate of soda*, E.; *Carbonate de soude sec*, Fr.; *Getrocknete Soda*, G.

Formula $\text{Na}_2\text{CO}_3 \cdot 2\text{H}_2\text{O}$. Molecular weight 142 (anhydrous $\text{Na}_2\text{CO}_3 = 106$).

Preparation.—Carbonate of Sodium 200 parts (4 oz.); to make 100 parts (2 oz.). Break the salt into small fragments, allow it to effloresce by exposure to warm air for several days, then expose it to a temperature of about 45°C . (113°F .) until it has been converted into a white powder weighing 100 parts. Pass the powder through a sieve and preserve it in well-stopped bottles.—*U. S.*

This is also the process of the German Pharmacopœia, and was admitted so as to facilitate the dispensing of carbonate of sodium. The warm air to which the crystallized salt is to be exposed in the beginning should be of a lower temperature than the melting-point (32.5°C .) of the salt, when a light and voluminous powder will be obtained. Working strictly according to the pharmacopœial directions, the salt will have the composition given above, and probably is a mixture of the mono- and terhydrated carbonate. Near and above 40°C . (104°F .) a salt of the formula $\text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{O}$ is readily obtained, weighing $1\frac{1}{2}$ oz., from 4 oz. of the crystallized salt. The product of the British Pharmacopœia is denser, the salt being at first fused in its water of crystallization, and afterward rendered anhydrous.

Properties.—Dried sodium carbonate is a soft white powder which answers to the tests and reactions of the crystallized salt. It is permanent at a temperature of 30° or 35°C . (86° or 95°F .), but at low temperatures absorbs moisture. 2.65 Gm. of the anhydrous salt, if pure, require for neutralization 50 Ccm. of the volumetric solution of oxalic acid; for the pharmacopœial salt not less than 36.3 Ccm. should be necessary, showing the presence of at least 72.6 per cent. Na_2CO_3 .

History.—Under NITRATE OF POTASSIUM allusion has been made to the confusion between nitrum and natron, nitre and soda, in medical and natural history. It is probable that anciently they were not clearly distinguished from one another. It appears that originally the term *nitre* was applied to native carbonate of sodium, and that the same name was afterward given to the substance procured by lixiviation from the ashes of the beech, oak, and other trees.

Soda was used by the ancients only as an external remedy for repressing fungous granulations, stimulating indolent sores, curing eruptions of the skin, lessening perspiration, whitening the teeth, and destroying vermin. It was habitually dissolved in water and applied as soap is at present, and baths of a strong solution of it were employed in the treatment of gout, tetanus, etc.

Physiological Action.—The nature of the action of carbonate of sodium must be closely analogous to that of the bicarbonate, but it differs in being much more irritating. In experiments on animals the continued use of it in large doses occasions loss of appetite, vomiting, diarrhœa, and sometimes albuminuria, followed by death. On dissecting, the gastro-intestinal mucous membrane is tumid, the follicles are enlarged, the Malpighian corpuscles of the spleen increased in size and number, the acini of the liver are degenerated, the renal tubules obstructed, and the gums swollen and spongy. In experiments on man the secretions at first diminish and the body gains weight; subsequently, a reverse effect occurs. These changes chiefly affect the watery element of the urine; the urea is undiminished, but the uric acid at first declines, to rise again subsequently, notwithstanding the continued use of the alkaline carbonate. However these things may be, carbonate of sodium is certainly diuretic when duly administered. According to current chemico-physiological doctrines, the carbonates are converted by the gastric juice into chloride of sodium, which in its turn increases the secretion of acid in the stomach and promotes the digestion of food. It may also tend to dissolve the glairy mucus which in certain dyspeptic conditions coats the interior surface of the stomach, hinders the close contact of the food with the mucous membrane, and thereby diminishes the acid secretion. It may also neutralize the fatty acids generated in the stomach, and which prevent the due digestion of starchy food, for which a feebly alkaline menstruum is necessary (Husemann).

Carbonate of sodium is generally assumed to promote the secretion of all mucous surfaces and glands, which is altogether probable on clinical grounds, although experiments do not demonstrate it.

Experimental researches have shown that when from 1 to 5 drachms of this salt are

daily taken by men for ten successive days the blood grows lighter in color, the proportion of its white corpuscles and water increases, while that of its other solid constituents declines and the clot exhibits a diminished firmness. Meanwhile, the strength is impaired and the skin grows pale. In excessive doses carbonate of sodium is irritant and corrosive, but not so much so as carbonate of potassium. Its proper *antidotes* are vinegar, lemon-juice, or a solution of tartaric acid. Subsequently cream or olive or almond oil may be administered.

Medical Uses.—In regard to the internal uses of carbonate of sodium little need be said in detail. They are the same as those of the bicarbonate, but they are much less frequently resorted to, on account of the greater mildness of the action of the latter salt. The carbonate is especially used now, as it was in ancient times, for the treatment of *diseases of the skin*. It is most frequently applied in a general bath, from 4 to 16 ounces of the salt being dissolved in a sufficient quantity of water at a temperature of about 80° F. Each bath should last for at least an hour. The effect of it is to redden the skin, to stimulate the affected portions to assume a more healthy action, and to remove the sebaceous and acid secretions adhering to it. If the skin is already in an irritable condition, very little of the alkali should be used, and its acrimony should be blunted by the addition of mucilage or bran to the water. Naturally, the dry eruptions (lichen, prurigo, lepra, psoriasis, pityriasis) are most apt to be benefited by this treatment, while pustular and vesicular affections (impetigo, eczema) are unsuited for its use, unless the solution is very weak. Lotions containing carbonate of sodium are useful in many local eruptions, as those of the scalp, in herpes circinatus, lichen agrius, intertrigo, and *pruritus of the vulva*. In some cases of inveterate scaly diseases, and in a less degree in chronic papular and pustular affections, the long-continued internal use of this medicine is sometimes curative, but seldom until it has produced more or less of the cachetic phenomena above mentioned.

Carbonate of sodium has also been employed in glandular *scrofula*, *whooping cough*, *congestion of the liver*, etc., but, except in the form of alkaline mineral waters, without notable advantage.

This salt is seldom administered internally, but its *dose* may be stated to be from 5 to 20 grains (Gm. 0.30–1.30), dissolved in water and largely diluted. From 2 to 8 ounces (Gm. 60–250) may be used in a general bath for diseases of the skin. A lotion for the same purpose should contain 15 or 20 grains to the ounce (Gm. 1.30 in Gm. 32) of water for scaly affections, and about half that proportion for lichenoid eruptions. A solution of the latter strength is appropriate as a wash for the mucous membrane of the female genital organs. An ointment for diseases of the skin may be made with about 1 drachm of the salt to an ounce (Gm. 4 in Gm. 32) of lard, with the addition of 1 or 2 fluidrachms (Gm. 8) of laudanum.

The medicinal qualities of dried carbonate of sodium are identical with those of the common carbonate. It is represented to be convenient for administration in pills, but the irritant qualities of the salt render this mode of prescribing it not only ineligible, but imprudent. The *dose* of it is stated to be from 3 to 10 grains (Gm. 0.20–0.60).

SODII CHLORAS, U. S.—CHLORATE OF SODIUM.

Natrium chloricum, *Chloras sodicus*.—*Chlorate de soude*, Fr.; *Natriumchlorat*, G.

Formula NaClO_3 . Molecular weight 106.5.

Chlorate of sodium should be kept in well-stopped bottles, and should not be triturated with readily oxidizable or combustible substances.

Preparation.—This salt is most conveniently obtained, according to Wittstein, by preparing sodium bitartrate from 9 parts of crystallized sodium carbonate and 9.5 parts of tartaric acid, and adding the hot solution to one containing 8 parts of potassium chlorate. The cold liquid is filtered from the precipitated potassium bitartrate, evaporated, and crystallized. The last traces of bitartrate may be removed by recrystallization from alcohol. The yield is about 7.5 parts. The salt is also formed, like the corresponding potassium salt (see p. 1218), by passing chlorine into solution of soda and boiling; the resulting chlorate requires to be freed from chloride by repeated crystallization, involving considerable loss, owing to the ready solubility of both salts.

Hager recommends the following: Dissolve 100 parts of potassium chlorate and 60 parts of officinal dry sodium carbonate in 600 parts of warm water; allow to cool, add 300 parts of alcohol, set aside in a cool place for two days, decant the solution, distil off the alcohol, evaporate to crystallization, and purify by recrystallization. The yield is about 85 parts.

Properties.—Sodium chlorate crystallizes in the form of regular cubes, combined with the dodecahedron and tetrahedron. The crystals are colorless and transparent, or the salt is seen in a white crystalline powder, and is permanent in the air, inodorous, and has a cooling saline taste and a neutral reaction. According to Kremers (1856), it dissolves

FIG. 284.

Crystal of Sodium Chlorate.

at	0°	20°	40°	60°	80°	100° C.,
in	1.22	1.01	.81	.68	.57	.49 parts of water.

The saturated solution boils at 132° C. (269.5° F.). The salt dissolves at 16° C. (60.8° F.) in 34 parts of 83 per cent. alcohol (Wittstein), in 40 parts of alcohol at 15° C., and in 43 parts of boiling alcohol (*U. S.*). When heated it melts, gives off oxygen and chlorine, and leaves a residue having an alkaline (neutral, *U. S.*) reaction. This residue is soluble in water, imparts to a non-luminous flame an intense yellow color, not appearing more than transiently red when observed through a blue glass, and its aqueous solution, acidulated with nitric acid, yields with test solution of silver nitrate a white precipitate soluble in ammonia.—*U. S.*

Tests.—"The aqueous solution of the salt should not produce a white crystalline precipitate on the addition of a saturated solution of bitartrate of sodium (absence of potassium). A dilute, aqueous solution should yield no precipitate with test solution of chloride of barium (sulphate) or of oxalate of ammonium (calcium), and at most only a faint cloudiness with test solution of nitrate of silver (limit of chloride)."—*U. S.*

Medical Action and Uses.—This salt is identical in the nature of its properties with chlorate of potassium, but its action is milder. It has been but little used. The *dose* may be stated at from 5 to 20 grains (Gm. 0.30–1.30), but it can seldom be needed as an internal medicine. As a gargle or wash a solution of from 2 to 5 per cent. may be prescribed.

SODII CHLORIDUM, *U. S.*, *Br.*—CHLORIDE OF SODIUM.

Natrium chloratum, P. G.; *Chloruretum sodicum*, *Sal commune*, *s. culinare*.—Common salt, Table-salt, Sodium chloride, E.; *Chlorure de sodium*, *Sel commun*, *Sel de cuisine*, Fr.; *Chlornatrium*, *Kochsalz*, G.

Formula NaCl. Molecular weight 58.5.

Origin and Preparation.—Chloride of sodium is found native in extensive beds and in different geological formations, though mostly associated with clay and sulphate of calcium, and constitutes *rock-salt* or *sal gem* if very pure and transparent. This is mined, mechanically freed from the adhering impurities, and sold as rock-salt or purified by recrystallization. In some places holes are dug into the rock and filled with water, which is pumped up when nearly saturated with salt and evaporated.

Most saline springs contain chloride of sodium. If the salt is present in sufficiently large proportion, it is recovered by evaporation; but if present in the solution only in limited proportion, the spring water is first concentrated, in some parts of France and Germany, by pumping it up on a high scaffolding and causing it to trickle over layers of brushwood, whereby, from the largely-extended surface exposed to the air, much water is evaporated, and a brine is obtained which may be economically concentrated by artificial heat. Sometimes the brine contains also considerable proportions of gypsum and sulphate of sodium, which salts are deposited from the boiling brine and raked out; when nearly free from these salts and sufficiently concentrated the liquor is no longer mixed with fresh portions of the brine, but is maintained at an elevated temperature and the salt removed as it crystallizes. The size of the crystals, called grain of the salt, varies with the heat, and increases as the temperature falls.

Sea-water is a solution of various salts, prominent among which is chloride of sodium, which is contained in the waters of the large oceans to the amount of from 2.6 to 2.9 per cent., but is much less in the large bays and seas which are surrounded by land, and sinks—for instance, in the water of the Baltic Sea—to $\frac{1}{2}$ per cent. The extraction of the salt from sea-water depends upon the climate, the water being removed either by freezing or by evaporation. When frozen, sea-water yields pure ice and leaves a more concentrated saline solution. In warmer countries the concentration is effected by spontaneous evaporation in shallow pits, the brine as it concentrates being conducted into other pits, and finally into reservoirs, where the salt is deposited.

The mother-liquors which are obtained in the several processes described are solutions of various salts, usually sulphates and chlorides, in some cases also of bromides of sodium, potassium, calcium, and magnesium, and they frequently yield salts or double salts of definite composition by being concentrated and exposed to either a low or an elevated temperature; they are used up in the preparation of sulphate of sodium, sulphate of magnesium, and bromine.

In addition to the large quantities of salt obtained in the United States, about 750,000,000 pounds of it are annually imported.

Properties.—When crystallized by spontaneous evaporation, chloride of sodium forms transparent cubes; but when the solution is evaporated at an elevated temperature, the crystals aggregate on the surface of the liquid in the form of white or translucent hollow pyramids. It is very frequently kept in the form of a white, granular, crystalline powder, which is inodorous and permanent in the air, unless contaminated with chloride of magnesium, when it becomes moist in a damp atmosphere. On the application of heat, chloride of sodium usually decrepitates, and at a red heat it melts and is slowly volatilized. It has a neutral reaction to test-paper, a density of 2.16, and a purely saline taste. It is very sparingly soluble in strong alcohol, and requires a little less than 3 parts of hot or cold water for solution. 100 parts of water dissolve at 0° C. (32° F.) 35.52 parts, at 14° C. (57.2° F.) 35.87 parts, at 25° C. (77° F.) 36.13 parts, at 60° C. (140° F.) 37.25 parts, and at 100° C. (212° F.) 39.61 parts, of chloride of sodium (Poggiale). On cooling the saturated aqueous solution to below the freezing-point of water, transparent colorless prisms, $\text{NaCl} \cdot 2\text{H}_2\text{O}$, are obtained, which melt above 0° C. (32° F.) and deposit a granular powder of the anhydrous salt. Dilute aqueous solutions of sodium chloride produce at a low temperature ice which is free from the salt, and concentrated solutions deposit crystals of the salt before they freeze. A fragment of the salt imparts to a non-luminous flame an intense yellow color, not appearing more than transiently red when observed through a blue glass; the aqueous solution, acidulated with nitric acid, yields with test solution of nitrate of silver a white precipitate soluble in ammonia.—*U. S.*

Composition.—Chloride of sodium contains 60.6 per cent. of chlorine and 39.4 per cent. of sodium. Heated with sulphuric acid, hydrochloric acid is given off.

Tests.—The aqueous solution of chloride of sodium should not be precipitated by carbonate of sodium (absence of calcium, magnesium, etc.), chloride of barium (sulphate), sulphuretted hydrogen, or sulphhydrate of ammonium (metals). "If 2 Gm. of the salt be digested with 20 Gm. of alcohol, the cold and filtered alcoholic solution evaporated to dryness, the residue dissolved in water, a little gelatinized starch added, and subsequently chlorine-water drop by drop, no colored tint should make its appearance at the line of contact of the two liquids (absence of iodide or bromide)."—*U. S.* Hager recommends for the same purpose the following simple test: Put into a dry test-tube sufficient of the powdered salt to form a layer about an inch (25 Mm.) thick; press it firmly with a glass rod, and add carefully twice this volume of a cold saturated solution of copper sulphate; the salt must retain its color and remain free from dark spots. (See SODII BROMIDUM.) "1 Gm. of chloride of sodium, when completely precipitated by nitrate of silver, should yield 2.450 Gm. of dry chloride of silver."—*U. S.*

Pharmaceutical Uses.—Chloride of sodium is used in the preparation of chlorine, hydrochloric acid, corrosive sublimate, and calomel.

History.—The economic and dietetic value of salt has been known from the remotest antiquity, and this, as well as its medicinal virtues, were dilated upon by Dioscorides, Pliny, and later authorities. Pliny, after speaking of its wonderful influence upon grazing animals, adds: "Ergo hercule vita humanior sine sale non quit degere: adeoque necessarium elementum est, ut transierit intellectus ad voluptates animi quoque. Nam ita sales appellatur." According to Dioscorides, salt is drying, astringent, and tonic. It preserves animal bodies from putrefaction for ages. Medicinally, it is stimulating, cleansing, and resolute. Mixed with various oils and other substances, it is used as an application for the stings of insects, the bites of serpents and other animals, etc.; it relieves headaches, cures bruises, heals ulcers, pustules, and papules, and represses the growth of warts and fungous granulations. It cures ulcers and swellings of the throat, mouth, and tongue, and a variety of cutaneous eruptions; mixed with wine, it is a wholesome purgative and anthelmintic; heated and enclosed in bags, it relieves muscular and other pains; and it is also an antidote to opium-poisoning. The Arabians dwell upon its dietetic virtues when eaten with fish, cheese, and food prepared with vinegar, and upon its power of sharpening the appetite and promoting digestion. They pronounced it fitter

for full-blooded persons than for the thin and nervous, and they used it as a topical application in leucoma, pterygium, granular lids, etc.

Physiological Action.—A strong solution of salt stimulates the skin and is generally said to irritate the mucous membrane, but a weak one smartens the nasal passages less than simple water—a fact which the use of the nasal douche has made familiar. Kept in contact with the skin, a strong solution excites a papular eruption. There is no evidence of the absorption of salt by the unbroken skin. The serum of the blood contains from 4 to 6 parts per 1000 of chloride of sodium, while the red corpuscles contain chloride of potassium. The former abounds more in arterial than in venous blood, and in the portal more than in the hepatic veins. Salt exists in all the secretions, and is the chief source of the muriatic acid secreted by the stomach. Its special action in the blood is held to be that it promotes the passage of albumen to and from the cells by the perpetual changes which it occasions in the relative densities of the fluids within and without them. A large increase in the proportion of salt used with the food causes a corresponding increase in the excretion of urea; at the same time it quickens tissue-change and raises the temperature of the body. A few days after the complete withdrawal of salt from the food gastric oppression occurs, with a sense of tightness in the head and general weariness. Albumen may appear in the urine, and, on the other hand, in albuminuria it sometimes diminishes the abnormal excretion. Salt in excess retards the coagulation of the blood and reddens it; and, conversely, when salt is deficient the blood grows dark.

In due proportion salt increases largely the secretions of the salivary and gastric glands, stimulating the appetite. It appears not to increase the secretion of bile. It promotes the digestion of vegetable food and renders it more apt for absorption. Hence, probably, the greed for salt of all herbivorous animals, and the utility of those "salt-licks" to which the bison, deer, and other wild animals resort. For this reason also, in part, it is customary to mix salt with the fodder of horses and horned cattle. It is related that during a famine in Cornwall, Eng., when the poor had only potatoes to eat, they declared that they would be contented if only they had salt to eat with them. "In Holland the ancient laws ordained men to be kept on bread alone, unmixed with salt, as the severest punishment that could be inflicted. The effect was terrible; these wretched criminals are said to have been devoured by worms engendered in their own stomachs" (Somerville).

Salt is useful also by exciting a thirst for liquids, which aid in the solution of the food and render it fitter for absorption. In moderate quantities it augments the urine, but if long and largely consumed it lessens this excretion and renders it irritating, unless the thirst which it excites is gratified with copious draughts of water. It is notorious that an exclusive diet of salt food tends to produce scurvy, one of the most deplorable incidents of a sailor's life on long voyages. In this disease there is an extravasation of the blood, which may be illustrated by the experiment of immersing a frog's foot in salt water; a free transudation of the red corpuscles takes place.

In very large quantities salt occasions vomiting or diarrhœa, or both. The case is recorded of a man who swallowed a pound of salt in a pint of ale. He died within 24 hours with all the symptoms of irritant poisoning. His stomach and intestines were found excessively inflamed (Christison). Taylor relates the case of a girl who took half a pound of salt to relieve herself of intestinal worms; general paralysis ensued, and death.

Medical Uses.—It has been proposed to use salt for the cure of *intermittent fever*, upon the ground that it causes contraction of the spleen enlarged by the disease. From half an ounce to an ounce has been given for this purpose during the apyrexia, and usually, unless dissolved in too much water, it neither vomits nor purges. This is said to be a popular medicine in some river localities and among boatmen, who usually swallow a tablespoonful or so of salt mixed with gin. It has also been recommended to be taken after being roasted in a pan over a gentle fire (*Med. Record*, xiv, 198). There is no sufficient proof of the efficacy of the medicine. A similar remark may be applied to its use in pulmonary *phthisis*, notwithstanding certain physicians of repute have attested its benefits. This judgment does not apply to an ordinary incident of consumption, *hæmoptysis*, for which a teaspoonful of dry table-salt may be given at intervals of 15 or 20 minutes. Nothing appears to be so successful in arresting this form of hæmorrhage, but all the ingenious hypotheses invented to explain its apparent action are chimerical. If the hæmorrhage, like most others, did not usually cease spontaneously when the patient is kept perfectly still, the action of the salt would be less ambiguous. The same

remarks are more or less applicable to the use of salt to arrest *epistaxis*, in which, however, it generally fails to give any evidence of hæmostatic virtues.

In the various forms of *scrofula* affecting the glands, the skin, or the bones salt has been used internally and externally, but chiefly in the latter mode, in sea-baths, and the baths of various mineral springs; and doubtless these agents are often useful through their stimulant operation, without any reference to their special saline constituents, in so far as they promote tissue-change. Gargles of salt water have been used with some advantage to promote the separation of the false membranes in *diphtheria*.

As salt is essential to the digestion of food, so is it of use in certain forms of *dyspepsia*, doubtless by promoting the secretion of the gastric juice, and perhaps also by its direct solvent action upon some kinds of aliment. It is especially indicated in those forms of dyspepsia which are attended with decomposition of the food in the stomach, causing flatulence, acidity, and pain, and either diarrhoea, as in children, or constipation, as in adults. It may be best administered in the form of natural mineral waters rich in this ingredient or in carbonic acid water.

In epidemic *cholera* the injection of salt and water into the veins has frequently been followed by temporary improvement; and it is claimed that a tablespoonful of a solution of 1 ounce of salt in $\frac{1}{2}$ pint of water, given by the stomach at intervals of a quarter of an hour, has repeatedly arrested the disease. If such be the fact, its explanation may probably be that the saline solution acts directly upon the cholera poison, whose influence upon the gastro-intestinal mucous membrane produces the serous exhalation which constitutes the primary element of the disease. In a number of cases life has been saved from impending death from *hæmorrhage* by injecting gradually into the median vein about 2 pints of distilled or boiled water holding in solution about 90 grains of common salt and 15 grains of carbonate of sodium (*Centrallbl. f. Therapie*, i. 387, 389). Salt is an ancient, and continues to be a popular, remedy for intestinal *worms*, especially for lumbricoid worms. There is no doubt that their production is favored by food that does not contain salt, and that a diet of salt food tends to dislodge them. Enemas of salt water form an excellent remedy for *ascarides* of the rectum. Probably in both cases the parasites are destroyed by the salt abstracting the water from their tissues. In a similar manner, when leeches are sprinkled with salt they are made to disgorge the blood which they have swallowed. It has been supposed that the anthelmintic virtues of helminthocorton, or Corsican moss, depend upon the saline element which saturates it.

Salt has been employed with some effect in *diabetes*, and certainly some of the mineral waters used in that disease contain it. But given in simple watery solution, it is alleged to reduce the proportion of sugar and the amount of urine voided.

It is a familiar fact that salt meat, olives, and other saline articles tend to prevent *alcoholic intoxication*, and enemas of salt water have been repeatedly employed with success to rouse drunkards from their lethargy or abate their delirious pugnacity. Similar injections are in common use to relieve *congestion of the brain*, which they do more speedily than can be explained by the mere removal of feces from the rectum. A teaspoonful of dry salt swallowed on the threatening of the *epileptic* paroxysm is a remedy that commands popular belief. Salt water is often employed as an emetic to empty the stomach gorged with food or containing *narcotic* or other *poisons*. Salt is a direct antidote to *nitrate of silver*, converting it into the comparatively innocuous chloride.

The local applications of salt are numerous. It is used to limit the action of nitrate of silver applied to the *eye*, *throat*, *vagina*, etc., in an atomized solution for the treatment of subacute and chronic affections of the *pharynx* and *larynx*, and by the nasal douche in *catarrh of the nostrils* and *ozæna*. The solution used for the latter purpose should not contain more than 20 grains of salt to a pint of water. Stronger solutions are apt to be painful and to aggravate the disease. A similar solution inspired from the hands while the head is bent forward almost horizontally will often answer the purpose as well. Salt and water may also be used as a wash for *mercurial sore mouth*, as an injection in vaginal *leucorrhœa*, as a wash for indolent *ulcers*, for *pruritus vulvæ*, and for the *stings and bites of insects*. Hot salt enclosed in bags is an excellent application in *colic*, *dysmenorrhœa*, *toothache*, and *muscular rheumatism*; a solution of it in whiskey is a popular remedy for the last-named disease and for disussing *bruises*, *glandular swellings*, etc.; and, finally, a warm salt footbath (100° F.) is one of the best palliatives of congestive *headache*, *uterine pain*, and similar disorders.

SODII HYPOPHOSPHIS, U. S., Br.—HYPOPHOSPHITE OF SODIUM (SODA).

Soda hypophosphis, Br. Add.; *Natrium hypophosphorosum*, *Hypophosphis sodicus*.—*Hypophosphite de soude*, Fr.; *Unterphosphorigsaures Natron*, G.

Formula $\text{NaH}_2\text{PO}_2 \cdot \text{H}_2\text{O}$. Molecular weight 106.

Preparation.—An aqueous solution of 6 parts of hypophosphite of calcium is accurately precipitated by a solution of 10 parts of crystallized carbonate of sodium; insoluble carbonate of calcium and soluble hypophosphite of sodium are produced and separated by filtration; on evaporating the filtrate, the latter salt is left behind, and if necessary may be freed from carbonate of sodium by redissolving it in alcohol, filtering, and evaporating. Berlandt (1865) recommends its preparation with granulated phosphorus (see p. 1172), of which $23\frac{1}{2}$ parts are macerated in a flask at 10°C . (50°F .) with 25 parts of caustic soda and 100 parts of water; after the phosphorus has been dissolved, the liquid is mixed with four times its volume of alcohol, neutralized with sulphuric acid, filtered, and evaporated. During the evaporation decomposition with explosion has occasionally been noticed, which was caused by too high a heat; the temperature of the evaporating solution should therefore be kept below that of boiling water.

Properties.—Hypophosphite of sodium is usually obtained in the form of a white granular powder, but by the slow evaporation of its alcoholic solution may be procured in pearly rectangular, tabular crystals, which, when dried over sulphuric acid and afterward heated not quite to 200°C . (392°F .), lose nearly 17 per cent. of water. At a higher heat spontaneously inflammable phosphoretted hydrogen is evolved, and a porous mixture of pyrophosphate and metaphosphate of sodium is left. The salt is inodorous, has a peculiar bitterish (sweetish, U. S.) saline taste, is deliquescent in the air, though less so than hypophosphite of potassium, and is easily soluble in water, and likewise in absolute alcohol, but is insoluble in ether. The U. S. P. states it to be soluble in 1 part of water and in 30 parts of alcohol at 15°C . (59°F .), in 0.12 part of boiling water and in 1 part of boiling alcohol. A fragment of the salt imparts to a non-luminous flame an intense yellow color, not appearing more than transiently red when observed through a blue glass. On triturating or heating the salt with an oxidizing agent the mixture will explode. The aqueous solution yields with test solution of nitrate of silver a white precipitate, which rapidly turns brown and black; and when acidulated with hydrochloric acid and added to excess of test solution of mercuric chloride, it first produces a white precipitate of calomel, and on further addition metallic mercury separates.—U. S. When evaporated with dilute nitric acid and finally ignited, a residue is obtained weighing 97 per cent. of the weight of the hypophosphite, and consisting of metaphosphate of sodium. Like all hypophosphites, the salt is oxidized on exposure to the air to phosphite and phosphate, and must therefore be preserved in well-stopped bottles.

Tests.—The aqueous solution of the salt should not effervesce on the addition of an acid (absence of carbonate), and should not be precipitated nor be rendered cloudy by test solution of oxalate of ammonium (absence of calcium) nor by a saturated solution of bitartrate of sodium (absence of potassium). After being acidulated with hydrochloric acid it should not produce a white precipitate or cloudiness with test solution of chloride of barium (sulphate). On mixing the aqueous solution with test mixture of magnesium, not more than a slight cloudiness should make its appearance (limit of phosphate).—U. S. 5 gr. of the salt dissolved in $\frac{1}{2}$ oz. of water, and boiled for ten minutes with $11\frac{1}{2}$ gr. of potassium permanganate, yields a nearly colorless filtrate.—Br.

Medical Action and Uses.—This salt has been administered in chronic *bronchitis* and in cases of *nervous depression* with a sense of heaviness or numbness in the limbs, in sexual *impotence*, and various other exhausted states of the nervous system, including those produced by *scrofula*, *syphilis*, and *anæmia*. This and the other alkaline and earthy phosphites and hypophosphites have also been used with alleged success in *phthisis*, but the allegations have been unsupported by the results of experience. The apparent value of the phosphatic compound in the above-named diseases is to be explained by the associated medicinal and hygienic treatment. The *dose* of hypophosphite of sodium is 8 grains (Gm. 0.50) or more given during digestion.

SODII HYPOSULPHIS, U. S.—HYPOSULPHITE OF SODIUM.

Natrium subsulfurosum (*hyposulfurosum*), *Hyposulphis sodicus*.—*Sodium thiosulphate*, E.; *Hyposulphite de soude*, *Sulfite sulfuré de soude*, Fr.; *Unterschwefligsaures Natron*, G.

Formula $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$. Molecular weight 248.

Preparation.—The process proposed by Walehner is as follows: A mixture of 3 parts of exsiccated carbonate of sodium and 1 part of sulphur is heated in a porcelain dish gradually to the fusing-point of sulphur, and repeatedly stirred to facilitate contact with the air. Sulphide of sodium is first formed, and then oxidized to sulphite, Na_2SO_3 ; this salt is dissolved in a little water, and by boiling with more sulphur converted into hyposulphite; the solution is filtered from the excess of sulphur, and the nearly colorless filtrate concentrated for crystallization.

In the purification of illuminating gas prepared from coal by dry lime, the *gas-lime* contains carbonate, hyposulphite, and pentasulphide of calcium, and is utilized for the manufacture of hyposulphite of sodium by a process proposed by Graham. The gas-lime is exposed to the air so as to convert the sulphide into hyposulphite; $2\text{CaS}_3 + 3\text{O}_2$ yields $2\text{CaS}_2\text{O}_3 + 3\text{S}_2$. It is then treated with its weight of cold water, and the filtrate, which contains the hyposulphite of calcium, is converted into the sodium salt by double decomposition with sodium carbonate, whereby insoluble calcium carbonate is produced and a solution of hyposulphite of sodium obtained, which is concentrated and crystallized; $\text{CaS}_2\text{O}_3 + \text{Na}_2\text{CO}_3$ yields $\text{CaCO}_3 + \text{Na}_2\text{S}_2\text{O}_3$. The residue left in the preparation of soda, called *soda waste*, contains sulphide of calcium, and is converted into hyposulphite of sodium by a process nearly identical with the one just described. In decomposing hyposulphite of calcium the sodium carbonate may be replaced by sodium sulphate, in which case sulphate of calcium is precipitated.

Properties.—Hyposulphite of sodium is in large, transparent, colorless, monoclinic prisms or plates which have the specific gravity 1.74, are neutral or faintly alkaline, are inodorous, and have a cooling, bitter, slightly alkaline, and sulphurous taste. It is permanent in the air, but over sulphuric acid it slowly parts with most of its water of crystallization (Letts, 1873), and in the atmosphere begins to effloresce at about 33°C . (91.4°F). (Pape, 1865). When slowly heated it parts with all its water of crystallization (36.3 per cent.) at 100°C . (Letts), but if rapidly heated not below 215°C . (419°F), and at about 225°C . (437°F) it is decomposed, with the separation of sulphur (Pape); at a red heat it forms a black (after cooling brown-yellow) mass of sodium sulphate and polysulphide, and a non-luminous flame is colored intensely yellow by the salt. This is fusible between 45° and 50°C . (113° and 122°F), and if melted in a clean flask, the liquid heated to boiling, and the flask instantly corked and slowly cooled, the mass will remain liquid until the cork is removed and the surface of the liquid is touched with a hard substance, when the whole will suddenly congeal, a considerable elevation of temperature being observed at the same time. The crystallized salt dissolves at 0°C . (32°F .) in .92 part, at 20°C . (68°F .) in .56 part, and at 40°C . (122°F .) in .25 part, of water, and readily forms supersaturated solutions (Kremers, 1856); it is slowly soluble in oil of turpentine, the odor of the latter being modified (Edison, 1876), but it is insoluble in alcohol, and is precipitated by the latter from its concentrated solution as an oily liquid. The aqueous solution is gradually, or in the presence of free alkali more rapidly, decomposed, sulphur being deposited, and in the presence of zinc and free acid sulphuretted hydrogen is formed; on acidulating the solution of the salt, thiosulphuric acid is liberated, and at once decomposed into sulphurous acid and sulphur, which forms a white precipitate (difference from sulphites).

Hyposulphite of sodium dissolves chloride, iodide, and other compounds of silver readily, and is employed for this purpose by photographers, and such a solution may be used for silvering copper and brass. Iodine is decolorized by a solution of hyposulphite of sodium, iodide and *tetrathionate of sodium* being formed, according to the equation $2\text{Na}_2\text{S}_2\text{O}_3 + \text{I}_2 = 2\text{NaI} + \text{Na}_2\text{S}_4\text{O}_6$. This reaction affords a convenient method for the estimation of iodine, 126.6 parts of which are decolorized by 248 parts of the hyposulphite. A similar reaction takes place with chlorine, and makes the salt a useful and cheap *antichlor* for the removal of chlorine retained by fabrics and other substances which have been bleached by chlorine. Hyposulphite of sodium is also a solvent for the insoluble salts of lead and other metals. It affords a white precipitate in a concentrated solution of chloride of barium, which is soluble in water.

Impurities.—If contaminated with sulphate or carbonate of sodium, the dilute solution of hyposulphite of sodium produces a white precipitate with solution of chloride of barium. "A solution of the salt in 80 parts of water should not be rendered cloudy by a few drops of test solution of chloride of barium (absence of sulphate), and a concen-

FIG. 285.

Crystal of Sodium Hyposulphite.

trated solution should not effervesce when added to diluted acetic acid (absence of carbonate). A solution of 2 Gm. of the salt in 10 Gm. of water, agitated for a short time with 1 Gm. of iodine, should yield a colorless liquid with at most only a faint white opalescence (corresponding to about 98 per cent. of pure hyposulphite of sodium).—*U. S.*

Medical Action and Uses.—This, among the compounds of sulphurous acid, has been perhaps most largely employed for the purpose of correcting the hypothetical fermentation to which a large number of febrile and other diseases has been attributed. But the results of experience are far from confirming faith in the hypothesis. The success of the medicine—in *erysipelas*, for example—is equally great whether the administration be internal or external; in other words, its direct action is purely negative, but indirectly it saves the sick from heroic perturbative treatment and allows the disease to run its normal course toward cure. The influence of the medicine over the course and issue of *typhus* and *typhoid fevers*, the *eruptive fevers*, *yellow fever*, *diphtheria*, and *puerperal infection* has been loudly proclaimed, but the proofs of its efficacy are wanting. On the other hand, there is some evidence in favor of its utility in *intermittent fever*; and although the natural tendency of this disease to cure under various circumstances must be admitted, the apparently almost uniform curative influence of the hyposulphite cannot rationally be denied.

A much more tangible evidence of its value is furnished by its use in the treatment of *dyspepsia*—not that it in the least acts upon any of the vital conditions accompanying gastric disorders, but it effectually prevents fermentation in the stomach and bowels, and thereby prevents acidity and flatulence, with their accompanying distress and their ulterior mischievous effects. In like manner, this medicine may be used to destroy the products of putrefactive fermentation, whether within the body or not. It will deodorize all *putrid products*, either after their discharge or while they are still in the stomach, rectum, bladder, vagina, uterus, etc. Atomized solutions of this and the allied compounds may be inhaled in *gangrene of the lung*, in *fetid bronchitis*, etc. Lancereaux has reported a number of cases of the latter disease cured by this medicine, given internally to the extent of 60 or 70 grains a day (Gm. 4-5) (*Bull. de thérap.*, ciii. 433). The dyspeptic fermentation referred to above is accompanied by the rapid development of low vegetable organisms, to which the compounds of sulphurous acid are hostile; and this mode of action has been invoked in the local treatment of *syccosis*, *furnus*, *impetigo*, etc. by means of a solution of about 40 grains of the hyposulphite, or, still better, of the sulphite, of sodium in an ounce of water (Gm. 3 in Gm. 32). A similar solution is useful as a lotion in *prurigo pudendi*. A saturated solution may be used in the proportion of about one-sixth to decolorize tincture of iodine.

The dose of hyposulphite of sodium is 15 grains (Gm. 1) and upward in copious watery solution.

SODII IODIDUM, *U. S.*, *Br.*—IODIDE OF SODIUM.

Natrium iodatum, P. G.—*Iodure de sodium*, Fr.; *Jodnatrium*, G.

Formula NaI. Molecular weight 149.6.

Preparation.—This salt may be obtained by processes analogous to those which afford iodide of potassium (see page 1229), either from iodine and solution of caustic soda or from decomposing a solution of iodide of iron with carbonate of sodium. The latter process is the more profitable one, since on the reduction of iodate of sodium by charcoal a portion of the salt is converted into carbonate of sodium.

Properties.—When crystallized at a temperature above 40° C. (104° F.), anhydrous iodide of sodium is obtained in cubes which are deliquescent on exposure and should therefore be kept in well-stopped bottles. This salt melts at a dull-red heat, and when fused in contact the air parts with a little iodine, at a higher temperature volatilizes slowly, but more readily than the chloride, and on cooling congeals to a pearly radiating crystalline mass. At ordinary temperatures the solution yields short monoclinic prisms or plates which have the composition NaI.2H₂O and the molecular weight 185.6, effloresce in dry air, on exposure are deliquescent, melt at a moderate heat in the water of crystallization, and become anhydrous. The U. S. P. describes the hydrated salt, but states that it melts without losing weight. The salt is usually prepared by evaporation to dryness in the form of a white crystalline powder, which is inodorous, of a saline somewhat sharp and bitterish taste, and has a neutral or faint alkaline reaction. According to Kremers (1856), 1 part of the anhydrous salt dissolves at 0° C. (32° F.) in .63 part, at

20° C. (68° F.) in .56 part, at 60° C. (140 F.) in .39 part, of water, the solubility increasing gradually to 1 part in .30 part of water at 141° C. (286° F.), at which temperature the saturated solution boils. The salt is also soluble in glycerin, in 3 (*P. G.*) or 1.8 (*U. S.*) parts of alcohol at 15° C. (59° F.), and in 1.4 parts of boiling alcohol. It differs from potassium iodide in not being precipitated from its concentrated aqueous solution by a concentrated solution of sodium bitartrate, and in imparting a yellow color to flame, which on being observed through a blue glass should not, or only transiently, appear red. On adding a little chlorine-water to the aqueous solution and agitating it with chloroform or carbon disulphide, these liquids will acquire a violet color.

Tests.—Contamination with iodide, chloride, bromide, and carbonate may be detected in the same manner as described on pp. 1230 and 1231. "The aqueous solution of the salt, mixed with gelatinized starch, and afterward with diluted hydrochloric acid, should not at once acquire a blue color (absence of iodate). If 1 Gm. of the salt be dissolved in 10 Cem. of water of ammonia, then shaken with a solution of 1.2 Gm. of nitrate of silver in 20 Cem. of water, and the filtrate be supersaturated with 7 Cem. of nitric acid, no cloudiness should make its appearance within ten minutes (absence of more than about 0.5 per cent. of chloride or bromide)." —*U. S.* The silver nitrate ordered in the last test is equivalent to 70.9 Cem. of the volumetric solution of this salt, while 67 Cem. are sufficient for completely precipitating 1 Gm. of the anhydrous iodide. The *P. G.* uses for this test .2 Gm. of anhydrous sodium iodide dissolved in 2 Cem. of ammonia-water, then mixed with 14 Cem. of the volumetric silver solution, and afterward acidulated with nitric acid. "On adding to 1 Gm. of the salt, dissolved in 20 Cem. of water, 5 or 6 drops of test solution of nitrate of barium, no immediate cloudiness or precipitate should make its appearance (limit of sulphate). 1 Gm. of the powdered and dried salt, when completely precipitated by nitrate of silver, yields, if perfectly pure, 1.566 Gm. of dry iodide of silver." —*U. S.* In addition to these tests, the *P. G.* directs testing for metals by hydrosulphuric acid, and for nitrate by nascent hydrogen (hydrochloric acid and zinc; see page 1231).

Medical Action and Uses.—In 1865 this salt was used with alleged advantage as a substitute for iodide of potassium in the treatment of constitutional syphilis, but it does not appear that the results then claimed have been confirmed by other observers.

SODII NITRAS, *U. S.*, *Br.*—NITRATE OF SODIUM (SODA).

Sodæ nitras, *Br.*; *Natrium nitricum*, *P. G.*; *Nitras* (*Azotus*) *sodicus*, *Nitrum cubicum*. —*Cubic nitre*, *E.*; *Azotate* (*Nitrate*) *de soude*, *Nitre cubique*, *Nitrate de Chili*, *Fr.*; *Natriumnitrat*, *Chilisalpeter*, *G.*

Formula NaNO_3 . Molecular weight 85.

A native salt, purified by crystallization from water.

Origin and Preparation.—Nitrate of sodium was first observed by Bohn (1683) on distilling a mixture of table-salt and nitric acid, and was prepared by Marggraf (1761) from calcium nitrate and sodium sulphate. In 1820 it became known through Mariano de Rivero that it exists in immense quantities in certain districts of Chili and Peru, where it is imbedded in clay and sand and more or less mixed with sulphates and chlorides of sodium, calcium, and magnesium. The stratum containing this saline mass, which is called *caliche* or *terra salitrosa*, is blasted, the salt extracted by boiling with water, and the decanted solution crystallized. In this condition nitrate of sodium is brought into the market in damp crystalline masses, which are more or less colored by intermixed earth and require to be purified by recrystallization. Previous to 1879 the United States imported about 50,000,000 pounds, but 184,598,857 pounds in 1882.

Properties.—Purified nitrate of sodium crystallizes in colorless, transparent rhombohedrons of the hexagonal system, which are permanent in dry air, slightly deliquescent on exposure, have a neutral reaction, and, according to Maumené (1864), dissolve

at	0°	10°	20°	40°	60°	80°	100°	119.5° C.
in	1.41	1.28	1.14	.92	.77	.65	.56	.47 part of water.

They are soluble in about 100 parts of strong alcohol, in 17 parts of 68 per cent. alcohol, in about 6 parts of 40 per cent. alcohol, in 40 parts of boiling alcohol, and slightly soluble in wood-spirit. The salt is inodorous, has a cooling, saline, and somewhat bitter taste, melts when heated to about 312° C. (594° F.), and congeals on cooling to a white mass. It is decomposed when heated to redness, oxygen being given off and sodium nitrite formed; but on continuing the heat, nitrogen and hyponitric acid are evolved and sodium

oxide and dioxide are produced. If thrown upon red-hot coal the salt deflagrates, and when mixed with inflammable substances it detonates less violently than nitrate of potassium. The hot aqueous solution, mixed with chloride, carbonate, or sulphate of potassium, yields crystals of potassium nitrate, and the cold solution, mixed

FIG. 286.

Crystal of Sodium Nitrate.

with strong sulphuric acid and ferrous sulphate, acquires a blackish-brown color. Non-luminous flames are colored intensely yellow by the salt, and when observed through a blue glass show merely transiently a red color.

Tests.—The aqueous solution (5 per cent., *P. G.*) should remain unaffected by hydrosulphuric acid and sulphide of ammonium (absence of metals), also by carbonate of sodium (alkaline earths), by oxalate of ammonium (calcium), by a saturated solution of bitartrate of sodium (potassium), by nitrate of barium (sulphate), or by nitrate of silver (chloride or iodide). The *P. G.* permits the presence of a minute trace of sulphate, and the *U. S. P.* admits a minute quantity of chloride, but to show that the faint opalescence by the silver salt was not produced by iodide, it directs testing the solution by mixing it with a few drops of hydrosulphuric acid and some gelatinized starch, and pouring

a few drops of chlorine-water on top, when no blue zone should make its appearance near the surface; iodate would give the same color. The *P. G.* directs testing for iodate by adding to the solution a little rasped tin, followed by 10 drops of nitric acid; the liberated iodine may be recognized by the violet color it imparts to chloroform or by the blue color it gives with starch. 1 Gm. of the salt, treated with an excess or about 1 Ccm. of sulphuric acid and afterward heated to redness until vapors cease to be given off, yields a residue weighing .835 Gm.—*U. S.*

Pharmaceutical Uses.—Nitrate of sodium is used in preparing nitric acid and arseniate of sodium.

Allied Salt.—SODII NITRIS. Nitrite of sodium, NaNO_2 ; molecular weight 69. It is conveniently prepared, according to Warrington (1865), by introducing, in small portions, into a heated iron crucible a mixture of 7 parts of sodium nitrate and 1 of starch. The decomposition is less violent than if charcoal be employed. The residue is dissolved in water, and on evaporation yields colorless somewhat deliquescent prisms which have an alkaline reaction and are nearly insoluble in strong alcohol. On exposure to the air the salt is slowly oxidized to nitrate.

Medical Action and Uses.—Nitrate of sodium, according to experimental investigations of its action, does not directly lessen the force or frequency of the pulse, nor lower the animal temperature, nor increase the elimination of urea. In large doses, acting as a purgative, it may produce these effects. Its solution dissolves false membranes. It has hence been used with the atomizer to diminish *fibrinous exudations* in the pharynx and larynx. In chief medicinal virtue is that of a mild purgative, and it has been used with advantage in *diarrhœa* and in *dysentery*. For these purposes it may be given in doses of 1 or 2 ounces (Gm. 32–64), dissolved in a large quantity of water.

NITRITE OF SODIUM. According to the experiments of Binz, it produces active hyperæmia of the stomach and paralyzes the nervous system, beginning at the brain, without inducing any excitation (*Archiv f. Pathol. u. Pharm.*, xiii. 133). Hay took on three occasions 5, 10, and 20 grains of this salt. The larger doses produced a feeling of fulness in the head and eyes, accompanied by a throbbing sensation which continued for an hour or more—effects resembling those of nitro-glycerin (*Practitioner*, xxx. 179). Hay prescribed it in a well-marked case of *angina pectoris* associated with defective aortic valves, in which, in doses of 2 or 3 grains, it relieved the patient of excruciating pain without producing any physiological phenomena. In 1882, Law proposed sodium nitrite for the treatment of *epilepsy*, and found it very useful in a single case (*Practitioner*, xxviii. 420). Shortly afterward Ralfe reported the results of the treatment in seventeen cases (*Med. Times and Gaz.*, Dec. 2, 1882, p. 707). The dose, according to him, should just fall short of producing its physiological effects. His conclusions were—1. That cases in which the bromides did good were not apt to be benefited by the nitrate, and *vice versâ*. 2. When the bromides begin to lose their effect or cause bromism, sodium nitrite is useful as a substitute. 3. It seemed to be especially useful in minor seizures and in convulsive attacks occurring at night.

SODII PHOSPHAS, *U. S., Br.*—PHOSPHATE OF SODIUM (SODA).

Sodæ phosphas, Br.; *Natrium phosphoricum*, P. G.; *Phosphas sodicus (natricus)*.—*Phosphate de soude*, Fr.; *Natriumphosphat*, *Phosphorsaures Natron*, G.

Formula $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$. Molecular weight 358.

Origin.—Phosphate of sodium exists in the urine of carnivorous animals and in other animal liquid. It was probably known to the ancients, since the *chrysocollo* used for soldering (see SODII BORAS) was at least partly obtained from urine. Hellot (1735) recognized it as distinct from the ammoniacal salts of urine, and Haupt (1740) named it *sal mirabile perlatum*, because it melts before the blowpipe to an opaque pearly bead. Proust (1775) stated it to be a compound of soda, and Klaproth and Scheele (1785) proved also the presence of phosphoric acid. The salt was employed medicinally by Pearson (1787), and was usually prepared by neutralizing phosphoric acid with sodium carbonate, but at present it is exclusively prepared from bone phosphate.

Preparation.—Take of Bone-Ash, in powder, 10 pounds; Sulphuric Acid 56 fluid-ounces; Distilled Water $4\frac{1}{2}$ gallons or a sufficiency; Carbonate of Soda 16 pounds or a sufficiency. Place the bone-ash in a capacious earthenware or leaden vessel, pour on the sulphuric acid, and stir with a glass rod until the whole powder is thoroughly moistened. After 24 hours add gradually and with constant stirring a gallon of the water; digest for 48 hours, adding distilled water from time to time to replace what has evaporated. Add another gallon of the water, stirring diligently, digest for an hour, filter through calico, and wash what remains on the filter with successive portions of distilled water till it has almost ceased to have an acid reaction. Concentrate the filtrate to a gallon, let it rest for 24 hours, and filter again. Heat the filtrate to near the boiling-point, add the carbonate of soda, previously dissolved in 2 gallons of the water, till it ceases to form a precipitate and the fluid has acquired a feeble alkaline reaction. Filter through calico, evaporate the clear liquor till a film forms on the surface, and set it aside to crystallize. More crystals will be obtained by evaporating the mother-liquor, a little carbonate of soda being added if necessary to maintain its alkalinity. Dry the crystals rapidly and without heat on filtering-paper placed on porous bricks, and preserve them in bottles.—*Br.* 1867.

The inorganic matter of bones consists of tricalcium phosphate, which is decomposed by sulphuric acid, with the formation of sulphate and acid phosphate of calcium, according to the equation $\text{Ca}_3\text{PO}_4 + 2\text{H}_2\text{SO}_4 = 2\text{CaSO}_4 + \text{CaH}_2\text{PO}_4$. The decomposition is known to be completed when the mixture is uniformly smooth and free from grittiness. On being treated with water the freely-soluble acid phosphate of calcium enters into solution, together with a small quantity of sulphate of calcium and any excess of sulphuric acid which may have been employed. On adding carbonate of sodium to the solution, the calcium salt is decomposed, one-half the phosphoric acid forming insoluble calcium phosphate, while the other half unites with the sodium of the sodium carbonate, forming disodium phosphate, liberating carbonic acid gas, and producing water; $\text{CaH}_2\text{PO}_4 + \text{Na}_2\text{CO}_3$ yields $\text{CaHPO}_4 + \text{Na}_2\text{HPO}_4 + \text{CO}_2 + \text{H}_2\text{O}$. The filtrate from the phosphate of calcium contains the sodium salts of phosphoric, sulphuric, and carbonic acids, of which the last two should be present in small quantity only, and requires to be evaporated to crystallization. If sulphuric acid and carbonate of sodium have not been used too largely in excess, the first crop or two of crystals will be pure phosphate of sodium, but those subsequently obtained are usually contaminated with carbonate and sulphate, and should be purified by recrystallization from water. 100 parts of calcined bones require from 60 to 70 parts of concentrated sulphuric acid and from 100 to 110 parts of crystallized carbonate of sodium, and yield between 100 and 105 parts of crystallized phosphate of sodium.

Properties.—This salt crystallizes in colorless, transparent, obliquely four-sided, monoclinic prisms, which have the specific gravity 1.55, react slightly alkaline upon test-paper, are inodorous, and have a cooling saline taste. The crystals effloresce rapidly in dry air, melt to a colorless liquid when heated to 35°C . (95°F .) (Kopp; 40°C . (*U. S., P. G.*), and congeal on cooling to a crystalline mass. At 100°C . (212°F .) they part with their water of crystallization, amounting to 60.3 per cent., and are converted into a white saline mass. Above 300°C . (572°F .) the basylous water is expelled and pyrophosphate of sodium is left. Crystallized phosphate of sodium requires for solution, according to Mulder (1864),

at 0°	10°	15°	30°	40°	60°	80°	99°	105°C .
24.12	15.5	10.4	2.5	.95	.66	.625	.611	.731 parts of water.

The solution saturated at a higher temperature deposits near 35° C. (95° F.) transparent crystals, which contain only 47 per cent. of water of crystallization and have the formula $\text{Na}_2\text{HPO}_4 \cdot 7\text{H}_2\text{O}$. Phosphate of sodium is insoluble in alcohol, and imparts a yellow color to flame, which, if observed through a blue glass, is not red, or only transiently so. The aqueous solution gives with silver nitrate a yellow precipitate soluble in nitric acid and in ammonia; with test mixture of magnesium, a white precipitate soluble in acetic acid; and with ferric chloride, a white precipitate insoluble in acetic acid.

Tests.—The solution should not effervesce with acids (absence of carbonate), should not be rendered turbid by ammonia (magnesium or traces of calcium), and should remain clear on the further addition of sulphide of ammonium. A 5 per cent. solution acidulated with hydrochloric acid should remain unaffected by hydrosulphuric acid (metals), and when acidulated with nitric acid should merely become faintly cloudy with barium nitrate (sulphate) or silver nitrate (chloride). Arsenic is detected by adding to the solution sulphuric acid, zinc, and a few drops of iodine solution (for oxidizing sulphite to sulphate), and covering the test-tube with filtering-paper moistened with a drop of solution of silver nitrate, which, if arsenic be present, will be colored yellow or brown (see page 65). If 1 Gm. of phosphate of sodium is completely precipitated by test mixture of magnesium, the washed, dried, and ignited precipitate should weigh 0.31 Gm.—*U. S.*

Composition.—This officinal salt is disodic orthophosphate or disodium hydrophosphate, and represents, in 100 parts, 19.9 parts of P_2O_5 , 17.3 parts of Na_2O , 2.5 parts of basylous H_2O , and 60.3 parts of water of crystallization.

Pharmaceutical Uses.—For the preparation of Ferri phosphas, *U. S.*, *Br.*; Sodii pyrophosphas, *U. S.*; and Syrupus ferri phosphatis, *Br.*

Allied Salts.—**SODII ET AMMONII PHOSPHAS**, $\text{NH}_4\text{NaHPO}_4 \cdot 4\text{H}_2\text{O}$ (mol. weight 418). This is the *microcosmic salt* of the alchemists, and was formerly prepared from urine. It is obtained by dissolving 5 parts of crystallized sodium phosphate and 2 parts of ammonium phosphate in 20 parts of hot water, adding a little ammonia until the liquid is alkaline, and crystallizing. The salt crystallizes in colorless, transparent, monoclinic prisms which are inodorous and have a cooling saline taste, and a neutral or faint alkaline reaction. It effloresces superficially on exposure, losing a little ammonia, melts readily to a colorless liquid in its water of crystallization, and at a red heat forms a colorless glass of sodium metaphosphate, which is used in blowpipe analysis.

POTASSII PHOSPHAS, *Phosphate of potassium*, K_2HPO_4 (mol. weight 174). This may be obtained from calcined bones in precisely the same manner as phosphate of sodium, only substituting in the process carbonate of potassium for carbonate of sodium, or by adding carbonate of potassium to dilute phosphoric acid until the liquid has a slight alkaline reaction, and by evaporating. The so-called neutral phosphate of potassium or dipotassium orthophosphate is with difficulty obtained in irregular crystals; usually it is a white amorphous or crystalline mass, of a saline taste, deliquescent in the air, and freely soluble in water. On the application of heat it melts, and at a red heat is converted into pyrophosphate of potassium, which is likewise very deliquescent. When dissolved in water it yields with nitrate of silver a yellow precipitate soluble in nitric acid, and with sodium bitartrate a white crystalline precipitate of cream of tartar. Both the mono- and tripotassium orthophosphates crystallize more readily than the preceding salt, and are easily soluble in water.

Medical Action and Uses.—Phosphate of sodium in solution injected into the veins is almost entirely eliminated with the urine. Taken internally, it is said to diminish the discharge of chloride of sodium by the kidneys. According to Rutherford and Vignal, it is a hepatic stimulant of considerable power. It has a cooling, saline, but not disagreeable taste, and has been used upon theoretical grounds as a remedy for *scrophula*, *rachitis*, *diabetes*, etc., but without encouraging results. Laton, however, claims that it rapidly and effectually cures those cases of *scrophulous ophthalmia* which are remarkable for lachrymation, photophobia, ulceration of the cornea, and associated impetiginous eruptions. In such cases from 40 to 70 grains (Gm. 3–5) must be given daily in divided doses (*Études de thérap.*, p. 387). It has been much recommended in the *bowel complaints* of children, for which its mild purgative action renders it well adapted when the use of purgatives of any sort is indicated. It is said, however, to be most suitable for the *diarrhæas* which are apt to occur at the period of weaning. It has been used with alleged success in correcting the acidity of the uterine and vaginal secretions, which was believed to destroy the spermatozoa after copulation. It was employed in injection before the act, and a course of alkaline mineral waters was at the same time prescribed (Charrier, *Bull. de thérap.*, xcvi, 492). Its purgative dose for an adult is about an ounce (Gm. 32); for children affected with diarrhæa the dose should be small, from 3 to 10 grains (Gm. 0.20–0.60), and may conveniently be given in milk and water.

SODII PYROPHOSPHAS, U. S.—PYROPHOSPHATE OF SODIUM.

Natrium pyrophosphoricum, Pyrophosphas sodicus.—*Pyrophosphate de soude, Fr.; Natriumpyrophosphat, G.*

Formula $\text{Na}_4\text{P}_2\text{O}_7 \cdot 10\text{H}_2\text{O}$. Molecular weight 446.

Preparation.—10 ounces of crystallized sodium phosphate are exposed to a warm atmosphere until effloresced, and then heated to dull redness until a small portion of the mass, dissolved in water, causes with silver nitrate a white precipitate free from yellow tint. The white salt is dissolved in 5 pints of boiling water and the solution filtered if necessary and crystallized. The total yield will be 6 ounces.

Properties.—The salt crystallizes in colorless or whitish transparent or translucent monoclinic prisms or plates which are inodorous and have a cooling saline taste and a feeble alkaline reaction. It is permanent in the air, but when moderately heated it gradually parts with its water of crystallization, and at a red heat melts to a transparent liquid which on cooling congeals to a white, opaque, crystalline mass. The salt is insoluble in alcohol, but, according to Poggiale (1863), it dissolves

at	0°	10°	20°	40°	60°	80°	100° C.
in	18.5	14.7	9.2	4.01	2.27	1.58	1.07 parts of water.

It colors non-luminous flames intensely yellow, and when observed through a blue glass a red color must only transiently appear. The aqueous solution causes a white precipitate with silver nitrate, and if an excess of the latter has been used the filtrate has a neutral reaction (difference from sodium phosphate). On boiling the aqueous solution with free mineral acids the salt is gradually converted into orthophosphate.

Tests.—"The aqueous solution of the salt should not effervesce on the addition of an acid (absence of carbonate). Acidified with hydrochloric acid, it should remain unaffected by hydrosulphuric acid or sulphide of ammonium (absence of metals), and when acidified with nitric acid it should not yield more than a faint opalescence with test solution of nitrate of barium (limit of sulphate) or nitrate of silver (limit of chloride)."

—U. S.

Off. Prep.—Ferri pyrophosphas, U. S.

Uses.—It is said that its action and uses are the same as those of sodium phosphate, but that it should be given in doses one-third less. Its pharmaceutical uses give it its chief value.

SODII SALICYLAS, U. S., Br.—SALICYLATE OF SODIUM.

Natrium salicylicum, P. G.—*Salicylate de soude, Fr.; Natriumsalicylat, G.*

Formula $2\text{NaC}_7\text{H}_5\text{O}_3 \cdot \text{H}_2\text{O}$. Molecular weight 338.

Preparation.—In addition to the processes on page 88, the following by Hager may be given: Dissolve 100 parts of salicylic acid in diluted alcohol, and add gradually pure sodium bicarbonate until effervescence ceases; 60 to 61 parts of the latter or from 38.2 to 38.4 of exsiccated sodium carbonate will be required; filter and evaporate. The yield is about 130 parts. If the solution of salicylic acid is added to the solution of the carbonate, the resulting salt will be colored.

Properties.—Sodium salicylate is a white crystalline powder or forms small white crystalline plates, is permanent in the air, inodorous or nearly so, and has a sweetish saline and mildly alkaline taste and a feebly acid reaction. It dissolves at 15° C. (59° F.) in 1.5 (U. S.), 0.9 (P. G.) parts of water and in 6 parts of alcohol, and is more freely soluble in boiling water and boiling alcohol. By heat the salt is decomposed, inflammable vapors are given off, and a carbonaceous residue of sodium carbonate is left, weighing about 31 per cent. of the salt used, and imparting to a non-luminous flame an intense yellow color, which should appear not more than transiently red when observed through a blue glass. Ferric chloride added to the concentrated aqueous solution of the salt colors it red-brown, but a very diluted solution is colored violet. The rather concentrated aqueous solution, when strongly acidulated with hydrochloric or sulphuric acid, gives a white crystalline precipitate, which is soluble in ether and in hot water and has all the properties of salicylic acid (see p. 87).

Tests.—"The aqueous solution should be colorless and should not effervesce on the addition of acids (absence of carbonate). Agitated with about 15 parts of concentrated sulphuric acid, the salt should not impart color to the acid within 15 minutes (absence of foreign organic matter). If a solution of 1 Gm. of the salt in a mixture of 50 Ccm. of

alcohol and 25 Ccm. of water be acidulated with nitric acid, the filtered solution should yield no precipitate, nor be rendered turbid on the addition of a few drops of test solution of chloride of barium (absence of sulphate) or of nitrate of silver (absence of chloride).—*U. S.* The tests ordered by the *P. G.* are nearly identical with the above. In the last test the addition of alcohol is made for the purpose of keeping in solution the salicylic acid liberated by the nitric acid, whereby filtration is avoided. The salt should not have the odor of phenol.

Allied Salts.—**POTASSII SALICYLAS**, $(KC_7H_5O_3)_2 \cdot H_2O$, is prepared like the sodium salt, 100 parts of salicylic acid requiring 72.5 parts of potassium bicarbonate. The salt crystallizes in colorless silky needles, is permanent in dry air, and is freely soluble in water.

SODII FORMIAS, $(NaCHO_2 \cdot H_2O)$, prepared by neutralizing formic acid with pure sodium carbonate or bicarbonate, crystallizes in colorless rhombic plates or prisms which are odorless, have a saline bitter taste, melt in their water of crystallization, are deliquescent in moist air, and dissolve freely in water.

Medical Action and Uses.—The great solubility of this salt, which is partly the reason of its milder action than that of the potassium salicylate, renders it in many cases preferable to the latter. Rutherford and Vignal declare it to be “a very powerful hepatic stimulant in the dog,” but no such action has been observed in man. Its medicinal uses are precisely the same as those of **SALICYLIC ACID**, under which the subject is fully treated. Its mode of action has been there considered, and shown to be quite inadequate to explain its therapeutical effects. The judgment of so eminent an authority as Vulpian may be here subjoined to illustrate still further the facility with which in such matters phrases take the place of facts: “The curative effects of sodium salicylate in acute articular rheumatism are due to the action of the salt upon the anatomical elements of the joints which are primarily affected by the disease. The medicine, becoming incorporated with them, renders them insusceptible to the specific irritation from which the rheumatism proceeds. If they are not already involved, as soon as the medicine acts upon them the acute rheumatism will no longer take hold of them in the greater number of cases. If they are affected, the irritation will rapidly decline. As soon as it has ceased the articular pains will abate, and then the swelling, and soon afterward the fever also. The disease, however, is not certainly cured when these phenomena subside, . . . for if the treatment is suspended they reappear; and not only so, but even while the medicine continues to be given, and several days after the joint affection has ceased, inflammation of the endocardium, the pericardium, or the pleuræ may arise” (*Du Mode d'Action du Salicylate de Soude*, 1881).

The dose of salicylate of sodium (as already stated under **SALICYLIC ACID**) should be about 20 grains, repeated five or six times a day in acute articular rheumatism. Smaller doses are not to be depended upon for checking the development or arresting the disease.

Potassium salicylate has been used as a substitute for the sodium salt in the treatment of rheumatism, and with alleged advantage (*Trans. Amer. Med. Assoc.*, xxxiii, 151), but confirmation of the statement is wanting.

Formiate of sodium has been proposed as a substitute for the salicylate in cases in which there may be danger from the renal congestion sometimes induced by the latter salt. According to Arloing (*Archives gén.*, Nov. 1879, p. 602), a 5 per cent. solution of the formiate of sodium gradually introduced into the blood of a dog or horse slows the heart and dilates the capillaries; in excessive doses it arrests the heart. Corresponding effects are produced on the respiration and calorification. We are not acquainted with any clinical experience with this compound.

SODII SANTONINAS, *U. S.*—SANTONINATE OF SODIUM.

Natrium santoninicum, s. *santonicum*.—*Santonate de soude*, Fr.; *Natriumsantoninat*, G.
Formula $2NaC_{15}H_{19}O_4 \cdot 7H_2O$. Molecular weight 698.

Preparation.—Heat in a water-bath $3\frac{1}{2}$ ounces of solution of soda diluted with 1 ounce of water, add 1 ounce of santonin, digest until the latter is dissolved, filter, wash the filter with a little hot water, and set aside in a cool place to crystallize. The decanted mother-liquor, concentrated by evaporation, will yield more crystals; when these are no longer obtained colorless, the mother-liquor is acidulated with hydrochloric acid, and the santonin which separates is collected separately. The yield is about $1\frac{1}{4}$ ounces of sodium santoninate.

Lepage (1876) proposed to prepare this salt by first forming santoninate of calcium, precipitating this solution by carbonate of sodium, evaporating the filtrate nearly to dry-

ness, and exhausting the residue with strong alcohol to remove excess of sodium carbonate; on evaporating the solution the salt crystallizes, leaving finally a colored mother-liquor.

Properties.—The salt crystallizes from alcohol in fine felt-like needles or small white prisms, and from water in rather large colorless and transparent or translucent rhombic tables or laminae, in which form it is usually seen. These crystals are nearly permanent in the air, a slight efflorescence being observed only after long keeping, and they are very slowly tinged yellow when kept in diffused daylight. The Pharmacopœia directs the salt to be kept in dark amber-colored, well-stopped vials, and not to be exposed to light. The salt is inodorous and has a saline and bitter taste and a slight alkaline reaction. It is soluble in 3 parts of water and in 12 parts of alcohol at 15° C. (59° F.), and it dissolves in .5 part of boiling water and in 3.4 parts of boiling alcohol (*U. S.*). It is insoluble in ether. At 100° C. (212° F.) it parts with its water of crystallization (18 per cent.), and at a somewhat higher heat it becomes bright red, the mass having a glassy lustre after cooling and becoming colorless by water; at a red heat the salt is completely decomposed, and an alkaline residue is left which imparts an intense yellow color to flame. The aqueous solution of the salt, acidulated with hydrochloric acid, deposits santonin, which is readily soluble in chloroform, and yields with alcohol, in the presence of caustic alkali or earth, a bright-red solution, becoming gradually colorless.

Tests.—“A 5 per cent. aqueous solution of the salt should not be precipitated nor be rendered turbid by test solution of carbonate of sodium (absence of alkaline earths), nor by picric or tannic acid (absence of alkaloids).”—*U. S.* The aqueous solution is not colored violet by ferric chloride (difference from salicylate).

Off. Prep.—Trochisci sodii santoninatis, *U. S.*

Allied Compound.—SODII SANTONINAS ALBUMINATUS. Digest santonin 1 part, sodium bicarbonate 4 parts, and dry soluble albumen 2 parts with about 50 parts of water at 60° C. (140° F.) until solution has been effected; filter, evaporate at a gentle heat, and dry on glass plates (Pavesi, 1876). This compound forms brilliant white scales having a pearly lustre and a bitter alkaline taste; its solution in water is decomposed by mineral acids with effervescence of carbonic acid gas, santonin and albumen being precipitated.

Medical Action and Uses.—This salt has over santonin the advantage of greater solubility—if that be indeed an advantage—for not only is its taste thereby rendered more distinct and disagreeable, but it is more readily absorbed from the stomach, and is therefore less apt to come into contact with the intestinal parasites it is given to destroy. In animals it produces poisonous effects more speedily than the proportion of santonin contained in it would do. Nevertheless, santoninate of sodium has been used with success as an anthelmintic, especially for *lumbricoid worms*. It may be prescribed for adults in doses of 8 or 10 grains (Gm. 0.50–0.60) twice a day, and for children in doses of from 2 to 5 grains (Gm. 0.10–0.30), mixed with sugar. After the second day a laxative, such as confection of senna or jalap and cream of tartar, should be administered to remove the worms. Enemata of water containing this salt may be used for rectal *ascarides*.

SODII SILICAS.—SILICATE OF SODIUM.

Silicate de soude, Fr.; Natriumsilikat, G.

(For preparation, properties, and tests see pp. 926, 927.)

Physiological Action and Medical Uses.—Silicate of sodium is remarkable for its power of arresting the putrefaction of organic matter. When 15 grains of it are added to 6 drachms of finely-hashed meat, mixed with 50 Cem. of water, putrefaction will not occur. Pus, blood, bile, and egg albumen are in like manner preserved by the addition of a 3 per cent. solution of the salt, which also prevents alcoholic fermentation. Given to dogs, it soon renders the urine turbid with silicic acid and the silicate, phosphate, and carbonate of sodium, but uric acid and its compounds disappear. On killing the animals, congestion of the kidneys and infarction of the renal tubules with silicic acid and its salts are found. Silicic acid is also detected in the muscles and the spleen, and the gastro-intestinal mucous membrane is inflamed or ecchymosed. Injected into the veins, a solution of silicate of sodium is fatal to life. Given to rabbits in the dose of 15 grains, it has produced alterations in the shape of the blood-corpuscles and fatty degeneration of the liver.

This salt has been applied to correcting the odor and preventing the consequences of putrefactive fermentation. Its solutions have been injected into the vagina in certain cases of *leucorrhœa* and *uterine ulceration*, into the urethra in *gonorrhœa*, into the bladder

in chronic *cystitis*, and into the nostrils in *ozæna*; but for all these purposes it is inferior to other stimulant antiseptics and astringents. Solutions containing the salt in the proportion of $\frac{1}{2}$ of 1 per cent. are employed. It has been applied in the same manner as collodion to the treatment of *erysipelas* of the face and other parts, care being taken that the preparation is neutral in its reaction. It has also been used, like starch and other substances whose solutions harden in drying, to prepare the so-called immovable bandages used in treating *fractures* and other surgical injuries. Silicate of potassium has been employed for the same purpose, and the solutions of both have been known as soluble glass.

SODII SULPHAS, U. S., Br.—SULPHATE OF SODIUM (SODA).

Sodæ sulphas, Br.; *Natrium sulphuricum*, P. G.; *Sulfas sodicus (natricus)*.—Glauber's salt, E.; *Sulfate de soude*, *Sel de Glauber*, Fr.; *Glaubersalz*, G.

Formula $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$. Molecular weight 322.

Origin.—Sulphate of sodium is found native in the anhydrous state and crystallized, and also in combination with sulphate of calcium. It is present in the water of many mineral springs and in that of certain lakes in Russia and in the western part of the United States. It is stated to have been known in Saxony for a century before it was obtained artificially by Glauber (1658) from the saline residue left in the preparation of hydrochloric acid, and was named after him *Sal mirabile Glauberi*. The same salt, prepared from the mineral spring at Friedrichshall, became known in 1767 as *Sal aperitivum Fridericianum*. It is largely manufactured in the United States, but small and variable quantities of it are also imported from abroad, the importation being 285 pounds in 1877 and 384,392 pounds in 1882.

Preparation.—This salt is largely obtained in many chemical processes, either as an intermediate or a secondary product, as in the preparation of soda by Leblanc's process; from the mother-liquors of the Stassfurt potash-works; in the preparation of carbonate of magnesium; in the manufacture of hydrochloric and nitric acids from chloride and nitrate of sodium; in the preparation of table-salt from many saline springs; in the manufacture of sal ammoniac from sulphate of ammonium and chloride of sodium; in preparing carbonic acid for the manufacture of mineral waters from bicarbonate of sodium and sulphuric acid; and in several other processes. Sulphate of sodium, as thus obtained, is purified by crystallizing it repeatedly from water, if necessary, after neutralization with sodium carbonate.

Properties.—Sulphate of sodium crystallizes in large, transparent, colorless, monoclinic prisms, which do not alter the color of red and blue litmus-paper, are inodorous, have a cooling, saline, and distinctly bitter taste, and rapidly effloresce on exposure to the air, leaving a white powder. The crystallized salt must therefore be kept in well-stopped bottles, and, on account of its low melting-point, in a cool place. At a temperature of 33°C . (91.4°F .) the salt melts, and a portion of it separates in the anhydrous state. It is insoluble in alcohol, but dissolves freely in water. Above the melting-point of the salt its solubility varies so little that 100 parts of water hold in solution, according to Mulder, at 35°C . (95°F .) 50.2 parts, and at 100°C . (212°F .) 42.5 parts, of Na_2SO_4 , or 1 part of the pharmacopœial salt dissolves at 35°C . in .32 part and at 100°C . in .478 part of water. At lower temperatures 1 part of the salt requires, according to Loewel,

at	0°	10°	15°	25°	30°	33°	34°C .
	8.23	4.33	2.78	1.02	.544	.31	.243 part of water.

On carefully cooling the solution and keeping it free from dust the liquid becomes supersaturated, but crystallizes on exposure. When heated the salt parts with its water of crystallization (55.9 per cent.), and at a full red heat melts without being decomposed, and congeals on cooling to a translucent, foliaceous, crystalline mass; at a white heat the salt is volatilized, with partial decomposition. It imparts a yellow color to flame, and its solution yields, with chloride of barium, a white precipitate which is completely insoluble in dilute nitric acid.

Tests.—A 5 per cent. aqueous solution of sulphate of sodium should not effervesce on the addition of hydrochloric acid (absence of carbonate), should not be colored or precipitated by sulphide of ammonium or sulphuretted hydrogen (metals), should not become cloudy by carbonate of sodium and heating (earths) or by nitrate of silver (chloride), and should not give off ammoniacal vapors on being treated with a warm solution of caustic soda (ammonium salt). The pharmacopœias permit the presence of a minute

quantity of chloride. 100 grains of it, dissolved in distilled water and acidulated with hydrochloric acid, give, by the addition of chloride of barium, a white precipitate which, after washing and drying, weighs 72.3 grains, or 1 Gm. yields .723 Gm. of BaSO_4 .

Composition.—Crystallized sulphate of sodium contains 55.9 per cent. water of crystallization, 24.85 per cent. SO_3 , and 19.25 per cent. Na_2O . Under certain circumstances the sulphate crystallizes with $7\text{H}_2\text{O}$, and then contains 47 per cent. of water of crystallization.

SODII SULPHAS EXSICCATUS, s. *Natrium sulfuricum siccum*, *P. G.* It is obtained by exposing the crystallized salt to a moderate heat until its weight has been reduced to one-half, when the white powder is passed through a sieve and preserved in well-stopped bottles. 4 parts of the completely dehydrated salt represent 9 parts of the crystallized salt; it contains 56.33 per cent. SO_3 and 43.67 per cent. Na_2O .

Physiological Action.—The mode of action of Glauber's salt does not differ essentially from that of other saline cathartics. Like them, it purges only when given in solutions of a certain degree of dilution, and not even then unless the dose exceeds a certain variable limit. In the dose of a drachm, for example, dissolved in 2 or 3 ounces of water, it will not usually act as a purgative, but it will cause more or less increase of the sulphates in the urine. In doses of from half an ounce to an ounce, dissolved in half a pint of water, it causes some nausea—by its repulsive taste chiefly—and, later, colicky pain, intestinal gurgling, and copious watery stools. By the following day the evacuations are usually no longer liquid. If the salt is frequently taken in full doses, it disturbs the digestive functions, causing impaired appetite, flatulence, and constipation; but weak solutions may be repeated for a long time without such consequences. According to Rutherford and Vignal, sodium sulphate is a hepatic stimulant, but not of great power.

Various views have been entertained of the mode of action of saline cathartics, but the one most generally accepted is founded upon the physical law governing the diffusion of liquids separated by a membrane or diaphragm. According to it, a thinner liquid on one side of the membrane will pass through it to a denser liquid upon the opposite side, until an equilibrium in density is established between them. Therefore, when a saline solution of greater density than the serum of the blood is introduced into the stomach and intestine, it will attract the water from the blood and give rise to more or less liquid stools. This plausible explanation, which is generally regarded as sufficient, has been supported by the results of certain experiments in which a saline solution was injected into the veins, causing, not purgation, but constipation. These conclusions have been substantially confirmed by Hay (*Boston Med. and Surg. Jour.*, Nov. 1882, p. 417). But similar experiments by other hands have led to opposite conclusions.

There is good reason to believe that too strong or too weak a solution of a purgative salt equally tends to hinder its operation. If the solution is weak and not bulky, it will act by the kidneys rather than by the bowels. Many persons are affected by natural purgative mineral waters in this manner, whatever may be their dose. On the other hand, it is of daily observation that just in proportion to the dilution of a saline cathartic is its relative efficiency as a purgative. An ounce of Glauber's or Epsom salt, if taken in just enough water to dissolve it, will usually not purge at all; but a single drachm of either salt in a pint of water will produce liquid stools. This fact is abundantly illustrated by the familiar effects of the saline mineral waters just referred to; they are purgative in doses which contain only an inconsiderable proportion of the neutral salts.

Medical Uses.—Glauber's salt is almost entirely supplanted by Epsom salt in this country and in England, but in Germany the former is in more common use. It is employed to relieve *plethora*, overcome *constipation*, and to act as a depletory and sedative remedy in various febrile affections, inflammatory and other. It has been especially used in weak solution in *typhoid fever* and in *dysentery*, and probably with more benefit and less mischief than any other active treatment of those affections. Of late years it has been strongly recommended in the form of Carlsbad water (which contains also a little chloride and carbonate of sodium), natural or artificial, in cases of simple *ulcer of the stomach*. The water is taken to the extent of about a pint, in divided doses, early in the morning, and fasting; or half an ounce of Glauber's salt may be dissolved in a pint of water and used in the same manner. It is said that in surgical poisoning with carbolic acid repeated dressings with a 5 per cent. solution of sulphate of sodium are a very efficient antidote (*Amer. Jour. of Med. Sci.*, July, 1879, p. 280).

The dose of sulphate of sodium as a purgative is from half an ounce to an ounce, dissolved in from 4 to 8 fluidounces (Gm. 16–32 in Gm. 120–250) of water. Its nauseous bitterness may be partially corrected by the addition of aromatic sulphuric acid or by

dissolving it in lemonade or in carbonated water flavored with syrup. Extract or fluid extract of liquorice may be used for the same purpose.

Sulphomethylate of sodium has recently (1879) been proposed by Rabuteau as a purgative salt. 10 Gm. of it, dissolved in 25 Gm. of water, injected into a dog's veins, occasioned constipation. 15 Gm. ($\frac{1}{2}$ ounce), dissolved in 2 wine-glassfuls of water and given to a woman in two doses, caused a free evacuation of the bowels. An examination of the urine showed that the salt was excreted as a sulphate. The salt is too unstable to become of practical value, although its freedom from unpleasant taste recommends it.

SODII SULPHIS, U. S., Br.—SULPHITE OF SODIUM.

Natrium sulfurosium, Sulfis sodicus (natricus).—*Sulfite de soude*, Fr.; *Natriumsulfit, Schwefligsaures Natron*, G.

Formula $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$. Molecular weight 252.

Preparation.—This salt is formed on passing sulphurous acid gas into a solution of carbonate of sodium until the color of blue litmus-paper is changed to red, or the solution of a known quantity of carbonate of sodium is completely saturated with sulphurous acid gas, whereby *bisulphite of sodium* is produced; an equal weight of carbonate of sodium is dissolved in the liquid, and the solution evaporated to crystallization. The sulphurous acid decomposes the carbonate of sodium, replacing the carbonic acid which is evolved; $\text{Na}_2\text{CO}_3 + \text{SO}_2$ yields $\text{Na}_2\text{SO}_3 + \text{CO}_2$.

Properties.—Sulphite of sodium crystallizes in colorless, transparent, monoclinic prisms, which are inodorous and have a slight alkaline reaction to test-paper and a cooling, saline, and sulphurous taste. The salt effloresces on exposure, and becomes opaque from the loss of water and from oxidation to sulphate, and therefore requires to be kept in well-stopped bottles. The solution is more rapidly oxidized than the salt, but does not separate sulphur; likewise, not on the addition of hydrochloric acid (difference from hyposulphite). When heated the salt loses its water of crystallization (50 per cent.), and yields a white powder without melting, but at a red heat fuses into an orange-red mixture of sulphide and sulphate of sodium. The salt is nearly insoluble in alcohol, but dissolves readily in water, the anhydrous salt requiring, according to Kreners (1856), at 0°C (32°F) 7.07 parts, at 20°C (68°F) 3.49 parts, and at 40°C (104°F) 2.02 parts, of water. On heating the aqueous solution, saturated in the cold, anhydrous salt is deposited (Rammelsberg). The dry, anhydrous salt Na_2SO_3 (mol. weight 156) is nearly permanent in the air, and when immersed in a little water combines with it and forms a solid mass. Muspratt obtained sulphite in oblique prisms containing $10\text{H}_2\text{O} = 58.8$ per cent. of water of crystallization, but even from supersaturated solutions the salt crystallizes of the above composition (Schultz). Diluted sulphuric or hydrochloric acid, added to the salt or its solution, liberates sulphurous acid, which is recognized by its odor. If held in a non-luminous flame an intense yellow color is imparted to the latter.

Tests.—A 1 per cent. aqueous solution of the salt, strongly acidulated with hydrochloric acid, should yield no precipitate, or at most only a white cloudiness, on the addition of a few drops of test solution of chloride of barium (limit of sulphate). If 0.63 Gm. of the salt be dissolved in 25 Ccm. of water, and a little gelatinized starch added, at least 45 Ccm. of the volumetric solution of iodine should be required before a permanent blue tint appears after stirring (corresponding to at least 90 per cent. of pure sulphite of sodium).—U. S. The absence of hyposulphite is shown by the test given above.

Composition.—The salt contains 24.6 per cent. Na_2O , 25.4 per cent. SO_2 , and 50 per cent. of water of crystallization.

Other Sulphites.—(See SODII BISULPHIS, p. 1385, and POTASSII SULPHIS, p. 1241).

SULPHITE OF AMMONIUM. NH_4HSO_3 , is precipitated in silky alkaline deliquescent needles on passing sulphurous acid into an alcoholic solution of ammonia.

SULPHITE OF CALCIUM is obtained as a white powder on mixing concentrated solutions of sulphite of sodium and chloride of calcium. It has an earthy and slightly sulphurous taste.

SULPHITE OF MAGNESIUM separates as a white powder on passing sulphurous acid gas into water containing magnesia in suspension. Its sulphurous taste is more marked than that of the calcium salt.

Medical Action and Uses.—These are essentially the same as have been described in connection with sulphurous acid, sulphite of potassium, and hyposulphite of sodium: that is to say, sulphite of sodium checks putrefaction and other forms of fermentation, and thereby tends to arrest the exhalation of the fetid gases which are formed during these processes. This action, as in the case of sulphurous acid itself, is a purely chemical

one, for it is neither more nor less certain in the laboratory than in the body. Like the other compounds of sulphurous acid with alkalis, sulphite of sodium has been vaunted as a remedy for the falsely-called zymotic diseases, but clinical experience has condemned this groundless assumption.

The dose of sulphite of sodium is from 20 to 60 grains (Gm. 1.30-4), largely diluted and frequently repeated. The solution may be flavored to conceal its taste. 1 part of the salt, dissolved in from 2 to 10 parts of water, may be applied externally, and solutions of half the latter strength or less may be injected into the bladder, vagina, etc.

SODII SULPHOCARBOLAS, *U. S.*, *Br.*—SULPHOCARBOLATE OF SODIUM.

Sulphophenate (Phenolsulphonate) of sodium, *E.*; *Sulphophénate de soude*, *Fr.*; *Phenylschwefelsaures Natron*, *G.*

Formula $\text{NaC}_6\text{H}_5\text{SO}_4 \cdot 2\text{H}_2\text{O}$. Molecular weight 232.

Origin and Preparation.—If 1 part of crystallized carbohic acid is dissolved in an equal weight of strong sulphuric acid, there results a new acid, *sulphocarbohic* or *ortho-phenolsulphonic acid*, which was discovered by Laurent (1841); $\text{C}_6\text{H}_5\text{HO} + \text{H}_2\text{SO}_4$ yields $\text{C}_6\text{H}_5\text{HSO}_4 + \text{H}_2\text{O}$. The mixture is digested for two or three days at a temperature of about 60°C . (122°F .), and then diluted with 20 parts of water. To the liquid are added in small quantities and with frequent stirring 2 parts of carbonate of barium until effervescence ceases, when a solution of *sulphocarbolate of barium* results, and a white deposit takes place, consisting of the excess of carbonate of barium employed and of sulphate of barium produced by free sulphuric acid. On adding carbonate of sodium to the filtrate double decomposition will take place, carbonate of barium being precipitated, while sulphocarbolate of sodium remains in solution and is obtained crystallized on concentrating the clear liquid. Sulphate of sodium may be substituted for the carbonate with identical results, except that the precipitate consists of sulphate of barium; and carbonate of lead may be used in place of carbonate of barium, sulphocarbolate of lead being likewise soluble in water.

Properties.—Sulphocarbolate of sodium is in “colorless, transparent, rhombic prisms, permanent in the air, odorless or nearly so, having a cooling, saline, somewhat bitter taste, and a neutral reaction; soluble in 5 parts of water, and in 132 parts of alcohol at 15°C . (59°F .), in 0.7 part of boiling water, and in 10 parts of boiling alcohol. When heated the salt loses its water and becomes a white powder. At a higher temperature it emits inflammable vapors having the odor of carbohic acid, and leaves a residue amounting to 36 per cent. of the original weight, the filtered solution of which, acidulated with nitric acid, produces a white precipitate with test solution of chloride of barium. A fragment of the salt imparts an intense yellow color to a non-luminous flame. The dilute, aqueous solution of the salt is colored violet by test solution of ferric chloride.”—*U. S.* When fused together with caustic potassa, pyrocatechin is obtained. If during the preparation of sulphocarbohic acid the temperature is permitted to rise to near the boiling-point of water, *paraphenolsulphonic acid* having the same composition as the acid described above is formed; it yields a sodium salt, which crystallizes in hexagonal tables without water of crystallization, is less freely soluble in water, and when fused with potassa yields small quantities of phenol and diphenol, but neither hydroquinone or resorcin; the last-named compound is obtained in the manner stated from *meta-phenolsulphonic acid* (Degener, 1879).

Tests.—“A 1 per cent. aqueous solution of the salt should not at once be rendered turbid or precipitated by test solution of chloride of barium (limit of sulphate).”—*U. S.*

Allied Compounds.—Other sulphocarbonates may be obtained by accurately precipitating a solution of sulphocarbolate of barium or of lead by a solution of the corresponding carbonate or sulphate, filtering, and crystallizing. They are all soluble in water, alcohol, and glycerin, and occasionally have a pinkish tint. The following have been employed:

SULPHOCARBOLATE OF POTASSIUM, $2\text{KC}_6\text{H}_5\text{SO}_4 \cdot \text{H}_2\text{O}$, crystallizes in shining needles, like the ammonium salt.

SULPHOCARBOLATE OF CALCIUM, $\text{Ca}_2\text{C}_6\text{H}_5\text{SO}_4 \cdot 6\text{H}_2\text{O}$, forms scaly crystals.

SULPHOCARBOLATE OF MAGNESIUM, $\text{Mg}_2\text{C}_6\text{H}_5\text{SO}_4 \cdot 7\text{H}_2\text{O}$, crystallizes in rhombic prisms or needles.

SULPHOCARBOLATE OF ZINC resembles the preceding in appearance. (See ZINCUM.)

The following acids are likewise known, but have not been employed in medicine: *Phenoldisulphonic acid*, $\text{C}_6\text{H}_4\text{O}(\text{HSO}_3)_2$, and *phenoltrisulphonic acid*, $\text{C}_6\text{H}_3\text{O}(\text{HSO}_3)_3$; they crystallize in deliquescent needles and are produced from phenol and sulphuric acid at elevated temperatures.

SODII CARBOLAS.—Carbolate (Phenate) of sodium, *E.*: Phénol sodique, *Fr.*: Natronphenylat, *G.*—Carbolic acid dissolves in solution of caustic soda as in other alkalis, and forms monosodium phenate, $\text{NaC}_6\text{H}_5\text{O}$, but, according to Berthelot (1871), neither basic nor acid compounds; such a concentrated solution may yield crystals of carbolic acid (see page 41). On treating phenol with an excess of melted alkali, Barth (1870) observed that about one-half of it is decomposed, with the formation of *diphenol*, $\text{C}_{12}\text{H}_{10}\text{O}_2$, and a small proportion of oxybenzoic and salicylic acids. On treating phenol with metallic sodium, sodium carbolate will crystallize in white needles. It is therefore difficult to obtain a definite compound in the solid state, but a solution of it is readily obtainable, and this dissolves notable quantities of carbolic acid. Such a solution was official in the P. G. 1872 as

LIQUR NATRI (SODII) CARBOLICI. It is prepared by melting 5 parts of pure carbolic acid, and adding 1 part of solution of soda spec. grav. 1.332 and 5 parts of distilled water. It is a clear liquid of a specific gravity varying between 1.060 and 1.065, has an alkaline reaction, and may be diluted with water or alcohol without being decomposed, but on the addition of acids carbolic acid is separated. Only one-seventh of the carbolic acid is combined with soda; the remaining six-sevenths are dissolved in the aqueous solution of carbolate of sodium.

Similar compounds, but made with impure carbolic acid, are often met with in commerce; on diluting them with water they separate most of the empyreumatic oils with which they are contaminated.

Medical Action and Uses.—The bodies of animals that have taken largely of this salt are said to resist putrefaction for a long time. This result is ascribed to its decomposition in the body into carbolic and sulphuric acid; or, rather, the latter acid in combination with sodium is eliminated along with the urine, while the carbolic acid exerts its characteristic influence in preventing organic decomposition. Given to man in doses of 20 or 30 grains (*Gm.* 1.30–2), it occasions no special symptoms; in twice or three times these doses it only causes some lightness of the head. It was at one time alleged to be a very efficient palliative in *phthisis* and to modify favorably the course of *typhoid fever* and the *eruptive fevers*, and was even vaunted as having a specific power in *scarlatina* (Sansom); but it has, in reality, as little efficacy in these diseases as the numberless other medicines to which similar virtues have been attributed. Miall claims that it arrests the *vomiting* of pregnancy. It may be useful in fermentative *dyspepsia*, like other carbolates. Like them, it exerts a more or less favorable action upon parts affected with pseudo-membranous exudation, especially when they tend to *gangrene* or become the seat of fetid decomposition, as in anginous *scarlatina* and *diphtheria*; and it also arrests the growth of *thrush*. Dr. Huse of Rockford, Ill., informs us that he cured all of thirty-six cases of diphtheria of the anginous form by giving from 15 to 40 grains of this salt every third or fourth hour. It may be administered internally in doses of from 10 to 30 grains (*Gm.* 0.60–2), and applied topically in a saturated aqueous solution. The medicinal value of the other sulpho-carbolates mentioned above is probably the same as that of the official compound.

SODII SULPHOVINAS.—SULPHOVINATE OF SODIUM.

Ethylsulphate of sodium, *E.*; *Sulforinate de soude*, *Fr.*; *Weinschwefelsaures Natron*, *G.*
Formula $\text{NaC}_2\text{H}_5\text{SO}_4\cdot\text{H}_2\text{O}$. Molecular weight 166.

Preparation.—The preparation of sulphovinate of sodium requires the previous formation of *sulphovinic acid* from alcohol and sulphuric acid, of which equal parts by weight are usually employed. On adding the sulphuric acid gradually to the alcohol, the mixture becomes hot and forms sulphovinic acid, by ethyl, C_2H_5 , of the alcohol taking the place of 1 atom of hydrogen in the sulphuric acid, water being formed at the same time; $\text{C}_2\text{H}_5\text{HO} + \text{H}_2\text{SO}_4$ yields $\text{C}_2\text{H}_5\text{HSO}_4 + \text{H}_2\text{O}$ (see page 122). The acid thus formed is invariably mixed with sulphuric acid, and if neutralized by caustic soda or sodium carbonate, the resulting solution requires to be mixed with an equal bulk of strong alcohol, in which the sulphate of sodium is insoluble, leaving an alcoholic solution of sulphovinate of sodium, from which the salt is obtained by evaporation. The use of alcohol for removing sulphate of sodium is best avoided by neutralizing the crude sulphovinic acid with carbonate of barium or carbonate of lead, whereby insoluble sulphate of barium or of lead is precipitated, while the corresponding sulphovinate is retained in solution, and, on being decomposed by an aqueous solution of carbonate or sulphate of sodium, and filtered from the insoluble barium or lead compound, is converted into sulphovinate of sodium, which should be evaporated at a moderate heat and crystallized. Marchand prefers adding carbonate of calcium to the crude acid, and decomposing the sulphovinate of calcium by carbonate of sodium. The yield is usually about equal to the weight of alcohol or of sulphuric acid used.

Properties.—Sulphovinate of sodium crystallizes in shining, transparent, flat, six-sided tables, which effloresce on exposure to dry air. When obtained by spontaneous evaporation the salt is granular and forms white opaque crystalline aggregations; and if crystallized from an alcoholic solution it contains alcohol in the place of water of crystallization. Heated to about 80°C . (176°F .), the crystals melt and rapidly part with their water, amounting to 10.8 per cent.; and if the heat is increased to 100°C . (212°F .) or a little above this point, the salt is decomposed, with the formation of sulphate of sodium, charcoal, heavy oil of wine, and of sulphurous acid, ethylene, and other gases. The aqueous solution of the salt when heated to boiling is decomposed, in the same manner as all sulphovinates, into alcohol, which distils off, and acid sulphate of sodium, this decomposition takes place more rapidly in concentrated than in diluted solutions. Crystallized sulphovinate of sodium dissolves at ordinary temperatures in a little more than half its weight of water, and is soluble in glycerin and ordinary alcohol, sparingly soluble in absolute alcohol, and insoluble in ether. Its solution is neutral to test-paper and has a slightly bitter afterward sweetish taste.

Tests.—The aqueous solution of the salt should yield only a slight precipitate with chloride of barium (sulphate), should not be colored by hydrosulphuric acid (absence of lead), and should not be rendered turbid by carbonate of sodium (absence of lead, barium, and calcium).

Allied Salt.—SULPHOMETHYLATE OF SODIUM, $\text{NaCH}_3\text{SO}_4\cdot\text{H}_2\text{O}$. This is prepared precisely like the preceding salt, except that methylic alcohol is substituted for ordinary alcohol. It resembles the sulphovinate in properties, and has been recommended for similar purposes.

Medical Action and Uses.—This salt was proposed as a laxative, on the ground of its being almost tasteless and having but little tendency to occasion colic; but, however real these advantages may be, they are outweighed by its liability to decomposition and to occasion unpleasant symptoms in consequence of its being imperfectly prepared. The *dose* is about $\frac{1}{2}$ ounce (Gm. 16) for an adult. A *tannate of sodium* has been proposed. It was made by dissolving 5 Gm. of tannic acid in 170 Gm. of water, and saturating with bicarbonate of sodium. A tablespoonful of it was administered every two hours in several cases of albuminuria, but in no instance did it lessen the discharge of albumen, and in more than one it seems to have been chargeable with producing fatal uræmia (*Centralbl. f. d. ges. Therap.*, i. 186.)

SODII VALERIANAS, Br.—VALERIANATE OF SODIUM (SODA).

Sodæ valerianas, Br.; *Natrium valerianicum*, *Valerianas sodicus* (*natricus*).—*Valérienate de soude*, Fr.; *Baldriansaures Natron*, G.

Formula $\text{NaC}_5\text{H}_9\text{O}_2$. Molecular weight 124.

Preparation.—Take of Amylic Alcohol (Fusel Oil) 4 fluidounces; Bichromate of Potash 9 ounces; Sulphuric Acid $6\frac{1}{2}$ fluidounces; Solution of Soda a sufficiency; Distilled Water $\frac{1}{2}$ gallon. Dilute the sulphuric acid with 10 fluidounces of the water, and dissolve the bichromate of potash in the remainder of the water with the aid of heat. When both liquids are cold, mix them with the fusel oil in a matrass, with occasional brisk agitation, until the temperature of the mixture has fallen to about 90°F . Connect the matrass with a condenser, and distil until about half a gallon of liquid has passed over. Saturate the distilled liquid accurately with the solution of soda, remove any oil which floats on the surface, evaporate till watery vapor ceases to escape, and then raise the heat cautiously so as to liquefy the salt. When the product has cooled and solidified, break it into pieces, and immediately put it into a stoppered bottle.—Br.

This is a modification of Trautwein's process (1845). An excess of sulphuric acid liberates from bichromate of potassium chromic acid, which in the presence of amylic alcohol is deoxidized, and then combines with the sulphuric acid to form chromic sulphate, while the amylic alcohol is oxidized to valerianic acid. The reaction takes place according to the equation $3\text{C}_5\text{H}_{12}\text{O} + 2\text{K}_2\text{Cr}_2\text{O}_7 + 8\text{H}_2\text{SO}_4 = 3\text{C}_5\text{H}_{10}\text{O}_2 + 2\text{K}_2\text{SO}_4 + 2\text{Cr}_2\cdot 3\text{SO}_4 + 11\text{H}_2\text{O}$. On subjecting the liquid to distillation, the residue in the retort will contain the sulphates of potassium and chromium, and in the distillate will be found the valerianic acid. A small portion of the fusel oil escapes oxidation, and is contained in the distillate combined with valerianic acid to *amylo-valerianic ether* or *amyl valerianate*, also known as *apple oil* from its odor when largely diluted; its composition is $\text{C}_5\text{H}_{11}\cdot\text{C}_5\text{H}_9\text{O}_2$. On the addition of caustic soda the valerianic acid is neutralized to valerianate of sodium, and the amyl valerianate separates as an oily liquid, which may, however, be

decomposed, by warming it with an additional quantity of soda, into valerianate of sodium and amylie alcohol. The latter separates as an oily stratum, which is removed, and the clear solution evaporated until all the water has been expelled.

Properties.—Thus prepared, valerianate of sodium forms a white crystalline mass which is rather unctuous to the touch, and has a neutral or slight alkaline reaction, a weak odor of valerian when perfectly dry, and a sweet and valerian-like taste. It melts at 140° C. (284° F.) without decomposition to a colorless liquid, and on cooling congeals crystalline; at a higher heat it gives off pungent acid vapors and inflammable gas, and leaves 42.75 per cent. of sodium carbonate. The salt is freely soluble in alcohol and water, and on exposure to the atmosphere liquefies from the absorption of water. (On the addition of diluted sulphuric acid a strong odor of valerianic acid is given off.)

Tests.—The solution of valerianate of sodium in water should not be colored by sulphuretted hydrogen and sulphhydrate of ammonium (absence of metals), and should yield no precipitate with chloride of barium (absence of sulphate).

Pharmaceutical Uses.—For the preparation of *Zinci valerianae, Br.*, and of *Acidum valerianicum*.

Medical Action and Uses.—This preparation is active only through the valerianic acid it contains. The complaints in which it is used, slight functional derangements of the nervous system, are much more efficiently relieved by the valerianate of ammonium. The *dose* is from 1 to 5 grains (Gm. 0.06–0.30).

SOLIDAGO.—GOLDEN ROD.

Verge d'or, Fr.; Goldrute, G.

The leaves and tops of *Solidago odora, Aiton.*

Nat. Ord.—Compositæ, Asteroideæ.

Description.—The *sweet-scented golden rod* is a native of the United States and Canada, and grows on the borders of woods and thickets and in dry or sandy fields. The stem is about 40 inches (1 M.) high, simple, slender, and nearly smooth, or somewhat pubescent in lines. The leaves are numerous, alternate, sessile, about 2 inches (5 Cm.) long, linear-lanceolate, entire, acute, pellucid-punctate, smooth, and on the margin somewhat rough. The flowers are in a terminal pyramidal panicle, composed of spreading racemes, bearing the flower-heads on one side; these are small, have lance-linear appressed yellowish scales, and contain three or four oblong ray-florets and several tubular disk-florets, all of a yellow color, and with terete akenes and a simple bristly pappus. The leaves when bruised have an agreeable anise-like odor and a sweetish aromatic taste. The flowers are likewise pleasantly aromatic; they appear in August and September. In some places the plant is known as *blue mountain-tea*.

Constituents.—The principal constituent is volatile oil; that obtained from the flowers differs from that contained in the leaves, which appears to be related to oil of anise.

Other Species.—*SOLIDAGO VIRGA-AUREA, Linné.* This is a variable species, indigenous to Europe, Northern Asia, and on this continent to Canada and the northern portion of the United States. It is from 2 to 3 feet (60–90 Cm.) high, branched above, has lanceolate or lance-oblong, petiolate, and more or less serrate leaves, and bears the flowers in erect simple wand-like racemes, forming a terminal panicle. The flower-heads contain eight or ten ligulate and several tubular disk-florets of a yellow color. The flowering herb has an aromatic odor and a bitterish and somewhat astringent taste, and has been used in Europe as *herba virgaureæ*. The oblique thin rhizome has likewise been employed.

Medical Action and Uses.—This plant, which grows profusely in the United States, owes its virtues to the volatile oil which it contains, and is stimulant, irritant, rubefacient, anodyne, and carminative. Its infusion is much used in country practice to produce *diaphoresis*, to allay *colic*, promote *menstruation*, and to cover the taste of nauseous medicines. For the last purpose the essential oil is to be preferred: it is also, like analogous products, sometimes used as a local anodyne in *neuralgia* and *rheumatism*.

An infusion may be prepared with an ounce of the herb and a pint (Gm. 32 in Gm. 500) of hot water, and given in *doses* of 2 or more fluidounces (Gm. 32–64). The oil may be prescribed in doses of 1 or more drops (Gm. 0.60).

SOPHORA.—SOPHORA.

Sophora speciosa, *Benth.*

Nat. Ord.—Leguminosæ, Papilionaceæ.

Description.—An evergreen ornamental shrub or small tree indigenous to Western Texas. It has smooth, oddly pinnate leaves, with three to five pairs of leaflets, which are about an inch (25 Mm.) long, ovate in shape, obtuse or somewhat pointed, dark-green and glossy above and pale-green beneath. The flowers are in dense racemes, blue or tinged with white, very fragrant, and have a bell-shaped small calyx and ten nearly free stamens. The pod is indehiscent, 2 or 3 inches (5–8 Cm.) long, nearly terete, or more or less constricted between the seeds, tough, and covered with a pale brownish-gray pubescence. The seeds are globular-ovate, about $\frac{2}{3}$ inch (1 Cm.) long, somewhat depressed on the hilum, and of a bright-red color.

Constituents.—Dr. H. C. Wood (1877) isolated from the seeds an alkaloid, *sophorine*, by macerating the powder for several hours in strong alcohol, exhausting it by water acidulated with hydrochloric acid, adding to the liquid an excess of carbonate of sodium, and agitating the mixture with chloroform. The chloroform solution is agitated with dilute hydrochloric acid, the aqueous liquid evaporated to a syrup, freed from gummy matter by strong alcohol, the alcohol evaporated, and the treatment with carbonate of sodium and chloroform repeated. *Sophorine* is nearly white, amorphous, yields with chromic and sulphuric acids a dirty deep-purple color, passing through bright-green and bluish into yellowish-brown, and produces with tincture of chloride of iron a deep almost blood-red hue, after a time acquiring an orange tint.

Allied Plants.—*SOPHORA SERICEA*, *Nuttall*, is herbaceous, about 10 inches (25 Cm.) high, silky-hairy, and grows from Nebraska and Colorado to Arizona and California. Examined by F. A. Wentz (*Rep. Commiss. Agric.*, 1879), the seeds as well as the root and plant yielded an alkaloid, which was not obtained pure, and may be identical with *sophorine* (see also p. 1317).

Physiological Action.—According to the experiments of Dr. H. C. Wood, its properties depend upon an alkaloid which in frogs produced a rapid loss of reflex activity and power of voluntary movement, due to its action upon the spinal marrow. In a cat a large dose of it speedily occasioned marked weakness in the limbs, disturbance of the respiration, and convulsive movements, with loss of consciousness. A smaller dose excited vomiting, great muscular weakness, profound quietude, and deep sleep, lasting some hours, and ending in recovery. It is stated that *sophora*-beans are occasionally used by the Indians in Western Texas as an intoxicant—that half a bean will produce a delirious exhilaration followed by a sleep that lasts for several days; and it is asserted that a whole bean will kill a man. The peculiarities of *sophora*-beans, as thus described, invite a fuller investigation (*Phila. Med. Times*, vii. 510).

SORBUS.—MOUNTAIN-ASH.

Sorbes, Fr.; *Eberesche*, *Vogelbeere*, G.

The fruit of *Sorbus* (*Pyrus*, *Gaertner*, *Mespilus*, *Scopoli*) *aucuparia*, *Linne*.

Nat. Ord.—Rosaceæ, Pomeæ.

Description.—This species of *Sorbus*, which is also known as *rowan tree*, is a medium-sized tree indigenous to Europe and Western Asia and cultivated for ornament in North America. It has oddly pinnate leaves, with obtuse, on the lower side downy leaflets, and bears numerous small, globular, juicy, berry-like fruits, which are of a bright-red color, are crowned by the calyx limb, contain three or four cells, each with two seeds, and have an acid taste.

The *American mountain-ash*, *Pyrus* (*Sorbus*, *Marshall*) *americana*, *De Candolle*, and *P.* (*Sorbus*, *Roemer*) *sambucifolia*, *Chamisso et Schlechtendal*, resemble the preceding species, and have similar but somewhat smaller fruits; the former species grows in the Alleghannies, the latter in the Rocky Mountains, and both extend to New England and far northward through Canada.

Constituents.—According to Liebig, mountain-ash berries when unripe contain tartaric acid, but when ripe malic and citric acids. Bysehl (1854) determined also the presence of tannin, acrid, bitter, and coloring principles, fermentable sugar, and of an amorphous, non-fermentable sugar, which had previously been obtained by Pelouze (1852) by setting the juice aside for about a year, and then evaporating and crystallizing. This *sorbin* crystallizes in colorless, hard, very sweet prisms, separates cuprous oxide from an alkaline solution of copper, is not altered by boiling with dilute acids, and has the com-

position $C_{12}H_{24}O_{12}$. It is not identical with *sorbit*, $2C_6H_{14}O_6 \cdot H_2O$, obtained by Boussingault (1872) from the fermented juice; this is isomeric with mannit and dulcitol, is very sparingly soluble in cold water, and melts at $102^\circ C.$ ($215.6^\circ F.$), and when anhydrous at $110^\circ C.$ ($230^\circ F.$). On preparing malic acid from the juice of mountain-ash berries, and distilling the mother-liquor after the separation of bimalate of calcium, G. Merk obtained an oily liquid which A. W. Hofmann (1859) recognized as a new acid, *para-sorbic acid*. This has an aromatic odor, does not displace carbonic acid from the carbonates, is slightly soluble in water, freely so in alcohol and ether, and when heated under pressure with caustic potassa is converted into crystallizable *sorbic acid*. Both acids have the composition $C_6H_8O_2$. Wicke (1851) obtained *amygdalin* from the bark and buds of the mountain-ash.

Medical Action and Uses.—The unripe fruit and the bark of the mountain-ash and its European congeners are extremely astringent, and are used in infusions, decoctions, and poultices to constrict relaxed parts, as the throat, anus, and vagina, and internally to check *diarrhœa*, etc. The ripe fruit is much used to prepare an infusion whose astringent and acidulous qualities render it a pleasant gargle in acute affections of the *tonsils* and *pharynx*.

SPIGELIA, U. S.—SPIGELIA.

Pinkroot, E.; *Spigelia du Maryland*, Fr.; *Marylandische Spigelia*, G.

The root of *Spigelia marilandica*, *Linne*. Bentley and Trimen, *Med. Plants*, 180.
Nat. Ord.—Loganiacæ.

Origin.—This plant is variously known as *Maryland pink*, *Carolina pink*, and *worm-grass*. It grows in rich shady woods, chiefly in the southern part of the United States, but is found northward to Pennsylvania and Wisconsin. The stem is from 10 to 20 inches (25–50 Cm.) high, simple, round below, quadrangular above, and has opposite, sessile, acute, ovate-lanceolate leaves, and a terminal spike of six or eight showy flowers, with funnel-form or somewhat club-shaped corollas, which are nearly 2 inches (5 Cm.) long, externally scarlet-red and internally yellow, and have the stamens exserted. The plant flowers in June and July, and produces two-celled and few-seeded capsules.

Description.—Pinkroot consists of a rhizome with numerous rootlets. The rhizome is from 2 to 4 inches (5–10 Cm.) long, simple or somewhat branched, bent in various directions, but generally horizontal, about $\frac{1}{4}$ inch (3 Mm.) thick, somewhat wrinkled longitudinally, frequently with a portion of the recent stem attached, and on the upper side with very short remnants of stems, which are from $\frac{1}{4}$ to $\frac{1}{2}$ inch (3–6 Mm.) apart and are terminated by cup-shaped scars. The numerous curved and bent fibrous rootlets emanate chiefly from below and the sides of the rhizome, and are about 4 inches (10 Cm.) long, brittle and angularly wrinkled longitudinally. The color is brown or purplish-brown; the rootlets are somewhat lighter. Pinkroot has a faint aromatic odor and a sweetish afterward slightly bitter, not disagreeable, taste. When the rhizome is cut transversely, there is seen a thin bark, with a dark outer layer and a light purplish-brown inner layer covering the pale-yellowish wood; the central pith is large, somewhat above the middle, and often discolored or decayed. The rootlets have a relatively thicker bark and no central pith.

Spigelia is occasionally seen mixed with a few roots of several plants, doubtless from careless collection, and has been observed as an accidental admixture in serpentaria. We have not observed any adulterations except earthy matter and stems, but we have frequently seen used in its place the root of *Phlox*, described below.

Allied Drugs.—SPIGELIA ANTHELMIA, *Linne*. This is an annual plant of the West Indies and South America, and has lance-ovate acute leaves, the upper ones being in whorls of four, and pale-reddish or purplish flowers not over $\frac{1}{2}$ inch (12 Mm.) long; its root is short, blackish, and internally whitish, and is divided into numerous long, thin branches. The plant has in the fresh state a nauseous odor, is bitter and acrid, and is employed like pinkroot.

PHLOX CAROLINA, *Linne* (nat. ord. Polemoniaceæ), together with one or more allied species, is known in some of the Southern States as *Carolina* or *Georgia pink*. That much of the commercial pinkroot is derived from this plant was shown by Dr. A. W. Miller (1875). This drug is of a lighter brown or brownish-yellow color, and consists of a rather knotty rhizome with thickish, straight, and rigid rootlets, from which the bark is easily removed, exposing a straw-colored ligneous thread. The root is employed like *spigelia*, and is said to be equally efficient. The root of *Phlox glaberrima*, *Linne*, appears to be likewise used in some localities; it is somewhat darker and less rigid than the preceding, and more closely resembles *spigelia*.

Constituents.—Pinkroot was examined by Dr. R. H. Stabler (1857), who found in it a little volatile oil, tasteless resin, wax, tannin, and a bitter principle which was not obtained in the pure state, but was ascertained to be not precipitated by acetate of lead, to be soluble in water and alcohol, and to be insoluble in ether; it appears to be precipitated by tannin. W. L. Dudley (1879) obtained, by distilling pinkroot with milk of lime, a volatile alkaloid, *spigeline*, which gives with iodine a brownish-red precipitate, with metatungstic acid a white flocculent precipitate, and with Mayer's test a white crystalline precipitate soluble in alcohol and ether, and differing from the precipitates of other alkaloids by this test in being soluble in acids.

The West Indian plant was analyzed by Feneulle (1823) and Ricord-Madiana (1828), but the active principle was not isolated.

Off. Prep.—Extract. *spigeliæ* fluid., *U. S.*

History and Physiological Action.—*Spigelia anthelmia*, it is stated by Murray (*Apparatus Medicam.* i. 545), was first brought into notice about 1750 by Browne, who said that it had long been used as a vermifuge by the Indians and the negroes of the West Indies and South America. On his recommendation it was introduced into England by Hinekley, Brocklesby, and others. Narcotic properties were attributed to it. *Spigelia marilandica* does not differ essentially from the species just described. It was used as a vermifuge by the aborigines of South Carolina, and was early employed by American physicians, who attributed to it both purgative and narcotic powers. The latter were even said to have caused death. Its toxic effects include nervous excitement of an hysterical sort, a hot and dry skin, pain in the forehead and eyes, stiffness and swelling of the eyelids, strabismus, dilatation of the pupils, temporary loss of sight, some drowsiness, but not narcotism, tremor of the tongue, general muscular trembling on making exertion, and even convulsions.

Medical Uses.—It is said that an infusion of *spigelia* is sometimes given as a substitute for ordinary tea to children liable to verminous disorders. It is so commonly associated with purgatives when used as an *anthelmintic* that it may be concluded to act upon intestinal worms by benumbing if not killing them, after which the associated medicine expels them from the bowels. In some states of chronic irritation simulating those which usually attend the presence of lumbricoid ascarides in the intestines *spigelia* is of marked advantage, but its mode of action is obscure. The most usual and the best form of the medicine is that known as "worm tea"—viz.: $\mathcal{R}$. *Spigelia* $\frac{1}{2}$ ounce (Gm. 16); senna and fennel-seed, of each 120 grains (Gm. 8); manna 1 ounce (Gm. 32); boiling water 1 pint (Gm. 500). Infuse. *S.* Half a wine-glassful three times a day for a child two years old. The fluid extract of *spigelia* and senna (*U. S. P.* 1870) represented this infusion sufficiently well. The proper remedies for the *toxic effects* of *spigelia* are wine, ammonia, and other diffusible stimulants.

SPILANTHES.—SPILANTHES.

Herba spilanthis.—*Para cress*, E.; *Cresson de Para*, Fr.; *Parakresse*, G.

Spilanthes oleracea, *Jacquin*.

Nat. Ord.—Compositæ, Senecionidæ.

Description.—This annual herb is indigenous to South America, naturalized in India, and is sometimes cultivated in gardens. Its ascending stem is about 8 inches (20 Cm.) long, and much branched. The leaves are opposite, petiolate, three-nerved, ovate, often subcordate, obtuse, or somewhat acute, repand-crenate and rough on the margin. 2 inches (5 Cm.) long, and of a pale-green color or somewhat purplish. The flower-heads are on long axillary peduncles, hemispherical in shape, about $\frac{1}{2}$ inch (12 Mm.) broad, have a chaffy receptacle, and contain numerous tubular florets, which are at first brown and afterward yellow. The herb is collected while flowering; it has a peculiar, not agreeable odor, and when masticated a sharp and biting taste, followed by a copious flow of saliva.

Constituents.—Lassaigne (1825) determined the presence in *Para cress* of tannin, producing green precipitates with ferric salts, and believed the acrid taste to be due to the volatile oil. Buchner (1831), however, attributed the taste to a soft resin resembling that contained in pellitory. Walz (1859) obtained from the alcoholic extract, by exhausting it with ether, a crystalline principle, *spilanthin*, which is not precipitated by acetate of lead, is insoluble in water, and when its solutions are rapidly evaporated is converted into a resinous mass.

Allied Plants.—*SPILANTHES ACMELLA*, *Linné*, s. *Acmeilla mauritiana*, *Richard*, is an annual East Indian herb with ovate or lance-ovate, serrate, pellucid-punctate, petiolate leaves, and small obconical flower-heads having five or six ligulate ray-florets. It has a bitter balsamic afterward biting taste, and is used like the preceding species.

XANTHIUM STRUMARIUM, *Linné*.—Cocklebur, *E.*; Lampourde, *Petit glouteron*, *Fr.*; Spitzklette, Knopf-klette, *G.*—This weed is common in waste places throughout North America, Europe, and Northern Asia. The stem is rough, about 18 inches (45 Cm.) high, and often spotted. The leaves are alternate, long-petiolate, triangular heart-shaped, slightly three-lobed, and rough-hairy. The sterile flowers are in short terminal spikes. The fertile flowers are numerous, in axillary clusters, and produce flat, oblong akenes, without pappus and enclosed in the enlarged involucre, which is oval or oblong in shape, nearly an inch (25 Mm.) long, beset with numerous hooked prickles, and terminates in two erect beaks. The variety *echinatum* has a more turgid prickly involucre and curved beaks. Zander (1881) obtained from 100 parts of the fruit 5.2 ash, 38.6 fat, 36.6 albuminoids, 1.3 xanthostrumarin and organic acids, besides sugar, resin, etc. *Nanthostrumarium* seems to be a glucoside, is yellow, amorphous, soluble in water, alcohol, ether, benzol, and chloroform, and yields precipitates with group reagents for alkaloids and with ferrie chloride, lead acetate, and salts of other metals, but is not precipitated by tannin or gelatin. M. V. Cheatham (1884) obtained only 14.5 per cent. of fixed oil, and a principle which was precipitated by tannin.

XANTHIUM SPINOSUM, *Linné*, Spiny clothur. It is indigenous to Southern Europe, but has become somewhat naturalized in the United States and most civilized countries, and grows in waste places and neglected fields. The stem is about 2 feet (60 Cm.) high, and has shortly petiolate, lanceolate, or ovate-lanceolate leaves, which are either cut-toothed or the upper ones entire, and have at the base sharp, three-forked, yellowish, stipulate spines, nearly an inch (25 Mm.) long. The fertile axillary burs are crowned with one inconspicuous beak.

Pharmaceutical Preparation.—*TINCTURA SPILANTHIS COMPOSITA*.—Compound tincture of spilanthes, *E.*; Teinture de cressen de Para, *Fr.*; Paratinktur, *G.*; also known as *Paraguay roux*.—Spilanthes herb and pellitory, of each 2 parts; alcohol sp. gr. .892, 10 parts.

Medical Action and Uses.—Every part of spilanthes has an aromatic and acrid taste, which excites free salivation. In its native country it is used as a remedy for *gout*, *rheumatism*, and *gravel*, and also as a diuretic in *dropsy* and as a *vermifuge*. In Europe it has been chiefly employed for the relief of *toothache*, and for many years a tincture made from the plant has been in popular use under the name of *Paraguay roux*. When the aching tooth is hollow the tincture is applied to the carious cavity on cotton, otherwise it is painted or rubbed upon the adjacent gum. It does not act as an irritant upon the latter.

XANTHIUM SPINOSUM. In some parts of Germany the powder or infusion of this plant has a popular reputation for the cure of *intermittent fever*. In Russia it is held to be a prophylactic against *hydrophobia*. Its efficacy is attested by Dr. Grzymala of Podolia, who states that when several animals or men had been bitten by a rabid dog those only escaped who were treated with this medicine, and that such results are usual, not exceptional. These statements, made in 1876, have not been confirmed. The physiological effects of the plant are said to resemble those of *jaborandi*, in being sudorific, sialagogue, and slightly diuretic. The dose of the dried powder of the leaves, repeated three times a day and continued for three weeks, is about 10 grains.

SPIRÆA.—HARDHACK.

Spiræa tomentosa, *Linné*.

Nat. Ord.—Rosaceæ, Roseæ.

Origin.—Hardhack, also known as *steeple-bush*, *whitecap*, and, like other species of the same genus, as *meadow-sweet*, is a small North American shrub growing from Canada southward to South Carolina. It is 3 or 4 feet (.9–1.2 M.) high, has a slender, reddish-brown, branching stem with hard brittle wood, and ovate-lanceolate, serrate, dark-green, and beneath rusty tomentose leaves. The root is branching, covered with a thin brown bark, and contains a whitish, hard, and tasteless wood; the taste of the bark is bitterish and strongly astringent. The small purplish-red flowers, with conspicuous stamens, are in short racemes crowded into a dense pyramidal panicle, make their appearance in July and August, and produce four or five one-seeded follicles. The plant, collected while in bloom, is often employed in preference to the root; it has an agreeable though not a strong aromatic odor, and a very astringent somewhat bitter taste.

Constituents.—Hardhack has not been analyzed; it evidently contains tannin, volatile oil, etc.

Other Species.—*SPIRÆA ARUNCUS*, *Linné*.—Goat's beard, *E.*; Barbe de chèvre, *Fr.*; Bocks-bart, *G.*—It grows in Europe and in North America westward from the Catskill and Alleghany Mountains. It is a perennial herb about 3 feet (90 Cm.) high, has smooth thrice-pinnate leaves, with thin, lance-oblong, sharply serrate, and pointed leaflets, and produces numerous small white flowers in slender racemes. It has an agreeable odor and an aromatic, astringent, and bitterish taste.

SPIRÆA ULMARIA, *Linné*, indigenous to Europe and cultivated in gardens, is an herbaceous perennial, with interruptedly pinnate leaves, the three to seven ovate or lance-oblong serrate leaflets being interposed with minute leaflets. The flowers are in long-peduncled corymbs, small, white, and in cultivation usually double. This, like other herbaceous species of *Spiræa*, contains *salicylic aldehyd* or *salicylic acid*, $C_6H_6O_2$, which may also be obtained from salicin, and is a colorless strongly aromatic oil which boils at $196^{\circ} C.$ ($385^{\circ} F.$), and in aqueous solution is colored dark-violet by ferric chloride.

SPIRÆA FILIPENDULA, *Linné*, likewise a European plant, has numerous long radicles, which near their lower end are enlarged to pear-shaped tuberous bodies, sometimes moniliform. These are 1 or $1\frac{1}{2}$ inches (25–38 Mm.) long, blackish-brown externally, internally pale red-brown, and have a sweetish, bitterish, and somewhat astringent taste.

Medical Action and Uses.—The late Drs. Griffith and Ives remarked that the officinal portion of the root (1870) is the least valuable part of the plant, the bark and the leaves being more efficient. It is said to have been used by the aborigines of this country, but was first brought to the notice of physicians in 1810. Its action was compared with that of rhatany, and it was alleged not to disorder the stomach even when taken in large doses. It was used in various forms of *diarrhœa*, including that of typhoid fever, pulmonary consumption, and summer complaint, in passive *hæmorrhages* and *menorrhagia*, in decoction as an injection for *leucorrhœa*, *gleet*, etc., and as a dressing for fungous ulcers. The extract has an agreeable odor and an astringent bitter taste, and may be prescribed in the *dose* of 5 grains (Gm. 0.30) or more. The decoction, made by boiling an ounce of the plant in a pint (Gm. 30 in Gm. 500) of water, may be given cold, in the *dose* of 1 or 2 fluidounces (Gm. 30–60). Although *S. tomentosa* is somewhat aromatic, it is less so than some other species, and especially *S. ulmaria*, which was formerly in vogue as a stimulant in *fevers*, as *serpentaria* is now used, and also for its astringent action in the diseases mentioned above. It appears to have displayed diuretic virtues in several forms of *dropsy*. In Europe an infusion, a decoction, and an extract of it are employed. To *S. ulmaria* has been attributed the power of overcoming *retention of urine* depending upon enlarged prostate and intercurrent irritation (*Edinb. Med. Jour.*, xxviii. 1036).

SPIRITUS.—SPIRITS.

Alcoolats, *Fr.*; *Geiste*, *G.*

Spirits were formerly prepared almost exclusively by distilling odorous substances with alcohol; at present, however, both the United States and British Pharmacopœias direct most of them to be prepared simply by dissolving the volatile oils and other volatile compounds in alcohol. Since odorous principles volatilize only sparingly with the vapors of alcohol, but more freely with the vapors of water, distilled spirits are made with alcohol sufficiently diluted with water, so that a portion of the latter remains in the still on the completion of the process. The German Pharmacopœia usually directs alcohol and water in the proportion of 3 parts of the former to 3 or 5 parts of the latter; after due maceration with the bruised drug 4 parts by weight of distillate are recovered. The alcoolats of the French Codex are generally made with 60 or 80 per cent. alcohol, the fresh drugs being used whenever practicable. In all cases the alcohol employed should be free from fusel oil, and the drugs should be well bruised and macerated with the alcohol for one or several days before distillation is commenced. In distilling spirits the same precautions should be adopted as in the distillation of medicated waters (see page 232), with this addition, that ample provision be made for the complete condensation of the vapors. Heat is best applied by means of steam or on a small scale by means of a salt-water bath.

SPIRITUS ÆTHERIS, U. S., Br.—SPIRIT OF ETHER.

Spiritus æthereus, *s. Liquor anodynus mineralis Hoffmanni*, P. G.; *Æther sulfuricus alcoolisatus*, F. P.—*Éther hydrique (sulfurique) alcoolisé*, *Liqueur anodine d'Hoffmann*, *Fr.*; *Hoffmannstropfen*, *G.*

Preparation.—Stronger Ether 30 parts (330 grains or 1 fluidounce); Alcohol 70

parts (770 grains or 2 fluidounces and 30 minims); to make 100 parts (about 3 fluidounces or $2\frac{1}{2}$ ounces av.). Mix them.—*U. S.* Ether 10 fluidounces; rectified spirit 20 fluidounces.—*Br.* Ether and alcohol, of each equal weight.—*F. Cod.* Ether 1 part, alcohol 3 parts.—*P. G.*

This preparation is used in Europe as a simplified form of *Hoffmann's anodyne* and for similar purposes.

SPIRITUS ÆTHERIS COMPOSITUS, *U. S., Br.*—COMPOUND SPIRIT OF ETHER.

Hoffmann's anodyne, E.; *Liqueur nervine de Bang*, Fr.; *Zusammengesetzter Aetherwein-geist*, G.

Preparation.—Stronger Ether 30 parts (10 oz. av. or $13\frac{1}{4}$ fluidounces); Alcohol 67 parts ($22\frac{1}{2}$ oz. av. or $26\frac{1}{2}$ fluidounces); Ethereal Oil 3 parts (1 oz. av.); to make 100 parts (or $33\frac{1}{2}$ av. oz. or $2\frac{1}{2}$ pints). Mix them.—*U. S.*

Oil of wine (undiluted) 3 fluidrachms; ether 8 fluidounces; alcohol 16 fluidounces.—*Br.* For preparing oil of wine the mixture of alcohol and sulphuric acid is directed to be distilled merely until it begins to blacken. (See pp. 1041, 1042.)

Properties.—Compound spirit of ether is a colorless inflammable liquid, entirely volatilized by heat, but when ignited on glass or porcelain it leaves an almost invisible residue having an acid taste and reddening blue litmus-paper. The spirit is neutral to test-paper, or has only a very slight acid reaction. It has an aromatic ethereal odor and a pungent, slightly sweetish taste. When mixed with water a whitish turbidity is produced from the separation of oil of wine, and a slight opalescence is still observed if 40 drops of the spirit are mixed with a pint of water. If adulterated with a fixed oil, this will separate from the water as a thin film, which, when absorbed by bibulous paper, produces a permanent greasy stain, not disappearing by heat. On evaporating some of the spirit with an excess of aqueous solution of chloride of barium, a white precipitate of sulphate of barium is produced.

The commercial compound spirit of ether is rarely made by the official formula, but is obtained, as was ascertained by Procter (1852), in the rectification of ether, the last fraction of the distillate, which is contaminated with light and a little heavy oil of wine, being diluted with alcohol and water so as somewhat to resemble the official article; from this it differs in producing only a slight precipitate with chloride of barium.

Medical Action and Uses.—This preparation is stimulant, anti-spasmodic, and anodyne, as are all preparations of alcohol, but in this one the addition of ether and ethereal oil renders its action more prompt and lively. Hence it is universally employed to allay restlessness, sleeplessness, and nervous disturbance in general, especially in the absence of fever, and notably in the manifold manifestations of *hysteria*. It is also a convenient remedy for flatulent and so-called uterine colic. It may, indeed, be used in all the cases for which sulphuric ether is prescribed internally, and with superior advantage. The dose is from $\frac{1}{2}$ to 1 fluidrachm (Gm. 2–4), properly diluted with sweetened water.

SPIRITUS ÆTHERIS NITROSI, *U. S., Br., P. G.*—SPIRIT OF NITROUS ETHER.

Spiritus nitri dulcis, *Spiritus nitricæ-æthereus*.—Sweet spirit of nitre, E.; *Éther azoteux alcoolisé*, *Liqueur anodine nitreuse*, Fr.; *Versüsster Salpetergeist*, G.

An alcoholic solution of ethyl nitrite ($C_2H_5.NO_2$; molecular weight 75), containing 5 per cent. of the crude ether.—*U. S.*

Preparation.—Nitric Acid 9 parts (9 oz. av.); Sulphuric Acid 7 parts (7 oz. av.); Alcohol, Distilled Water, each a sufficient quantity. Add the sulphuric acid gradually to 31 parts (31 oz. av. or $36\frac{1}{2}$ fluidounces) of the alcohol. When the mixture has cooled, transfer it to a tubulated retort connected with a well-cooled condenser, to which a receiver, surrounded by broken ice, is connected air-tight, and which is further connected by means of a glass tube with a small vial containing water, the end of the tube dipping into the latter. Now add the nitric acid to the contents of the retort, and, having introduced a thermometer through the tubulure, heat rapidly, by means of a water-bath, until strong reaction occurs and the temperature reaches $80^\circ C.$ ($176^\circ F.$). Continue the distillation at that temperature, and not exceeding $82^\circ C.$ ($200^\circ F.$), until the reaction ceases. Disconnect the receiver, and immediately pour the distillate into a

flask containing 16 parts (16 oz. av. or $15\frac{1}{2}$ fluidounces) of ice-cold distilled water. Close the flask and agitate the contents repeatedly, keeping down the temperature by immersing the flask occasionally in ice-water. Then separate the ethereal layer, and mix it immediately with nineteen times its weight of alcohol. Keep the product in small glass-stoppered vials, protected from light.—*U. S.*

Take of nitric acid 3 fluidounces; sulphuric acid 2 fluidounces; copper, in fine wire (about No. 25), 2 ounces; rectified spirit a sufficiency. To 1 pint of the spirit add gradually the sulphuric acid, stirring them together; then add, in the same way, $3\frac{1}{2}$ fluidounces of the nitric acid. Put the mixture into a retort or other suitable apparatus into which the copper has been introduced and to which a thermometer is fitted. Attach now an efficient condenser, and, applying a gentle heat, let the spirit distil at a temperature commencing at 170° F. and rising to 175° F., but not exceeding 180° F., until 12 fluidounces have passed over and been collected into a bottle kept cool, if necessary, with ice-cold water; then withdraw the heat, and, having allowed the contents of the retort to cool, introduce the remaining $\frac{1}{2}$ ounce of nitric acid, and resume the distillation as before until the distilled product has been increased to 15 fluidounces. Mix this with 2 pints of the rectified spirit, or as much as will make the product correspond to the test of specific gravity and percentage of ether separated by chloride of calcium. Preserve it in well-closed vessels.—*Br.*

The second formula gives the process of Prof. Redwood (1867), and yields good results if proper attention be paid to the strength of the acids and the alcohol, and to the temperature; it is, however, best adapted for being worked on a small scale. The sulphuric acid, in the presence of nitric acid, dissolves the copper, forming sulphate of copper and setting nitrous acid free, which in its nascent state acts upon the alcohol, producing nitrous ether and water. The reaction is explained by the equation $C_2H_5HO + HNO_3 + H_2SO_4 + Cu = C_2H_5NO_2 + CuSO_4 + 2H_2O$. (An elaborate paper on the manufacture by this process of spirit of nitrous ether of the strength required by the U. S. P. was read by Prof. Diehl (1877) before the Louisville College of Pharmacy.)

Older formulas differ from Redwood's either in acting upon alcohol directly by nitric acid or in generating nitric acid from nitrate of potassium and sulphuric acid in the presence of alcohol. In either case the result is much influenced by the strength of the acid and by the temperature, and a larger quantity of aldehyd is always thus produced than in the presence of copper. The action of nitric acid upon alcohol and the production of aldehyd are explained by the equation $2C_2H_5HO + HNO_3 = C_2H_4O + C_2H_5NO_2 + 2H_2O$. The German Pharmacopœia directs a mixture of 12 parts of alcohol and 3 of nitric acid to be set aside for 12 hours, and then distilled until 10 parts are obtained, the distillate being neutralized with magnesia and rectified.

In the process of the U. S. P. the reaction likewise takes place between the nitric acid and alcohol, the sulphuric acid serving mainly the purpose of uniting with the water which is formed during the reaction. According to Prof. H. B. Parsons (1883), only about one-half the alcohol is used in the production of nitrous ether, and the process is therefore an expensive one; it is, however, easily carried out on a small scale if proper precaution is taken for not exceeding the temperature mentioned in the formula and for the condensation of the ethereal vapors. By washing with water the distillate is freed from various acid products likely to be present, and by using for this ice-cold water only a small amount of ether will be lost in the operation.

Other processes which have been at various times recommended require the previous preparation of nitrite of potassium or of sodium, and the decomposition of one of these salts by sulphuric acid in the presence of alcohol. It has likewise been suggested to prepare this spirit from pure nitrous ether or nitrite of ethyl by mixing it with alcohol in a definite proportion. This would doubtless be the most rational way of preparing the spirit, but the obstacles to it are the difficulty of obtaining the ether in the pure state, and, after it has been obtained, in the preservation of it.

NITRITE OF ETHYL, $C_2H_5NO_2$, is a thin, pale-yellow liquid having a pungent, ethereal, apple-like odor. It boils at 17.5° C. (72.5° F.), is somewhat soluble in water, and on keeping acquires an acid reaction.

Properties.—Prepared by either process, spirit of nitrous ether is a transparent, volatile, inflammable, and nearly colorless liquid, with a slight yellowish or greenish-yellow tint, and has an agreeable, ethereal, somewhat fruit-like odor, free from pungency, and a sharp and burning, or, after diluting with water, a sweetish and cooling ethereal, taste. It mixes with water in all proportions, the liquid remaining clear and transparent. It does not alter the color of blue litmus-paper or merely reddens it slightly, and should effe-

vesce not at all on the addition of a crystal of bicarbonate of potassium. If agitated with a solution of ferrous sulphate and a little strong sulphuric acid, it acquires a dark olive-brown tint. If mixed with half its volume of officinal solution of potassa previously diluted with an equal measure of distilled water, it assumes a yellow color, which slightly deepens, but does not become brown, in 12 hours, showing the absence of undue proportions of aldehyd. The spirit of the Br. P. contains about 10 per cent. of nitrous ether and has the specific gravity 0.845; the U. S. P. requires 5 per cent. of ether and a specific gravity of 0.828–0.825.

Tests.—"A portion of the spirit, in a test-tube half filled with it, plunged into water heated to 63° C. (145.4° F.), and held there until it has acquired that temperature, should boil distinctly on the addition of a few small pieces of glass. If 10 Gm. of spirit of nitrous ether be macerated with 1.5 Gm. of potassa for 12 hours, with occasional agitation, the mixture then diluted in a beaker with an equal volume of water, and set aside until the odor of alcohol has disappeared, then slightly acidulated with diluted sulphuric acid, and a solution of 0.476 Gm. of permanganate of potassium gradually added, the color of the whole of this solution should be discharged (presence of at least 4 per cent. of real ethyl nitrite)."—*U. S.* The first test, determining the beginning of boiling at the temperature indicated, is valuable only in connection with the other properties. The quantitative determination of the nitrous ether is done by the process suggested by E. Kellstroem (1880). "10 Gm. of the spirit should not have an acid reaction after 3 drops of volumetric solution of potassa have been added (limit of free acid)."—*P. G.* The *Br. P.* requires the spirit when fresh to yield 7 times, and when old about 5 times, its volume of nitric oxide gas. Eykman (*New Remedies*, May, 1882) generates this gas by heating the spirit with an acid solution of ferrous sulphate; and Allen (*Phar. Jour.*, 1885, xv. 673) by treating the spirit with potassium iodide and sulphuric acid.

Preservation.—Spirit of nitrous ether should be kept in small well-filled and well-stopped bottles and not exposed to the direct sunlight. The concentrated spirit obtained by distillation may be preserved in the same manner, and if well washed with ice-cold water requires merely dilution with alcohol to furnish an unexceptionable preparation. The free acid which is formed by the influence of atmospheric oxygen may be neutralized by magnesia or by potassium bicarbonate, but the spirit should not be kept continuously in contact with these chemicals. It has, however, been recommended, and is now directed by the *P. G.*, to keep in the bottle with the spirit some crystals of potassium tartrate, whereby free acid will be neutralized, a corresponding amount of potassium bitartrate being formed.

Off. Prep.—*Mistura glycyrrhizæ comp., U. S.*

Medical Action and Uses.—The vapor of this liquid, breathed by rabbits and cats, rapidly occasions spasms, followed by death, after which the blood is found liquid and dark and the lungs and brain congested. When inhaled by man it causes giddiness, headache, throbbing of the arteries, and (in excessive quantities) confusion of mind, muscular reaction, cyanosis, a thready pulse, and spasms. Prolonged immersion in its vapor has been fatal. In very large doses it irritates the stomach, especially if the preparation contain, as it often does, free acid, causing vomiting and colic. In medicinal doses it is decidedly diuretic or diaphoretic, according as the skin is cool or warm. In *febrile conditions* it is much used to promote critical sweating, which it probably does by abating the morbid activity of the heart and tension of the arteries. Its efficacy in this respect is very marked in slight and ephemeral febrile affections, especially such as are produced by an arrest of perspiration. It is usually associated with the neutral or the effervescing mixture and minute doses of some antimonial preparation.

As a *diuretic* it is commonly employed to relieve *strangury* produced by cantharides, in all painful affections of the *urinary apparatus*, whether occasioned by calculous or inflammatory disorders, and in the various affections of the *kidneys* in which congestion of those organs and diminished secretion of urine occur. In all of these cases the medicine should be associated with diluent drinks, weak saline solutions, or diuretic infusions. Of salines the most suitable are the acetate, tartrates, and carbonates of potassium, and of vegetable infusions those of digitalis and juniper. In chronic renal dropsy it is less useful than in dropsy of cardiac origin.

This medicine is often serviceable in relieving *flatulent* distension of the stomach and *nausea*, especially when it is associated with aromatic spirit of ammonia. It is in common use to quiet *nervous agitation*. It may be inhaled with advantage to allay *coughing* in diseases of the air-passages. It is a soothing application to the forehead in neuralgic *headache*, but if frequently applied it irritates the skin, especially if it is not freshly pre-

pared. It is said to have cured certain hard swellings of the lip supposed to be cancerous (*papilloma, epithelioma*), but which are most generally non-malignant.

The *dose* of spirit of nitrous ether in febrile affections is from 20 to 30 drops (Gm. 1.30–2), repeated every half hour or hour and given in sweetened water. As a diuretic from $\frac{1}{2}$ to 1 fluidrachm (Gm. 2–4) of it should be given every three or four hours in a diuretic mixture, solution, or infusion. As a nervous stimulant the dose should not be less than a fluidrachm (Gm. 4).

SPIRITUS AMMONIÆ, U. S.—SPIRIT OF AMMONIA.

Liquor ammonii caustici spirituosus; Spiritus ammoniaci caustici Dzondii.—Ammoniated alcohol, E.; *Alcoolat ammoniacal, Liqueur d'ammoniaque vineuse*, Fr.; *Weingeistiges Ammoniak*, G.

Preparation.—Stronger Water of Ammonia 45 parts ($4\frac{1}{2}$ oz. av. or $4\frac{1}{2}$ fluidounces); Alcohol, recently distilled and which has been kept in glass vessels, a sufficient quantity. Pour the stronger water of ammonia into a flask connected with a well-cooled receiver, into which 80 parts (8 oz. av. or $9\frac{1}{2}$ fluidounces) of alcohol are introduced. Heat the flask carefully and very gradually to a temperature not exceeding 60° C. (140° F.), and maintain it at that temperature for about 10 minutes. Then disconnect the receiver, and, having ascertained the ammoniacal strength by means of the volumetric solution of oxalic acid, add enough alcohol to make the product contain 10 per cent. by weight of ammonia. Keep the product in glass-stoppered bottles in a cool place.—*U. S.*

In the former editions of this work we have pointed out the disadvantages of the process of 1870, which directed the generation of ammonia from ammonium chloride and lime, and showed the convenience of evolving the gas from stronger ammonia-water without unduly contaminating the alcohol with water. This is the process now adopted. 45 parts of stronger ammonia-water of full strength contain 12.6 parts of ammonia, one-half of which is readily given off at a temperature not exceeding 45° C. (113° F.); but 8 parts of ammonia being required for 80 parts of alcohol, a somewhat higher heat is required, which, however, should not exceed 60° C. (140° F.). After the evolution of ammonia ceases, the ammoniacal alcohol (8.5 Gm.) is tested with oxalic acid in the manner directed by the Pharmacopœia, and if more than 50 Ccm. of the volumetric acid are needed for neutralization, the alcohol required for dilution is readily calculated; but if the liquid becomes neutral with a smaller quantity of the volumetric solution, the alcohol should be further charged with ammonia gas evolved from a fresh portion of strong ammonia-water; increasing the heat is inadmissible, since too large a proportion of water would pass over. Alcohol which has been kept in a barrel is apt to contain more or less organic matter in solution, which would be darkened in color by ammonia; hence the recommendation to use only alcohol which after rectification has been preserved in glass vessels.

Properties.—Spirit of ammonia is a colorless liquid having a strong ammoniacal and at the same time spirituous odor and a spec. grav. of about .810. When diluted with water it has the same behavior to reagents as ammonia-water, and its purity and strength may be determined in the same manner as for the latter. “8.5 Gm. spirit of ammonia, diluted with distilled water, should require for complete neutralization 50 Ccm. of the volumetric solution of oxalic acid (= 10 per cent. NH_3).”—*U. S.*

Medical Action and Uses.—The action and uses of this preparation have been described under AMMONIA. It is seldom prescribed internally, the aromatic spirit and the fetid spirit being more appropriate for this purpose as a general rule. It has the advantage of not rendering turbid mixtures containing resins and other substances which are precipitated by water, and hence it is a common ingredient in stimulating liniments, of which it should form not more than one-sixth part. Its *dose* is from 10 to 30 drops (Gm. 0.60–2) in a wine-glassful of water.

SPIRITUS AMMONIÆ AROMATICUS, U. S., Br.—AROMATIC SPIRIT OF AMMONIA.

Alcoolat ammoniacal aromatique, Fr.; *Aromatischer Ammoniakgeist*, G.

Preparation.—Carbonate of Ammonium 40 parts (1 oz. av.); Water of Ammonia 100 parts ($2\frac{1}{2}$ oz. av. or $2\frac{1}{2}$ fluidounces); Oil of Lemon 12 parts (131 grains or $2\frac{1}{2}$ fluidrachms); Oil of Lavender-Flowers 1 part (11 grains or 12 minims); Oil of Pimento 1 part (11 grains or $10\frac{1}{2}$ minims); Alcohol, recently distilled and which has been kept in

glass vessels, 700 parts (17½ oz. av. or 20½ fluidounces); Distilled Water a sufficient quantity; to make 1000 parts (25 oz. av.). To the water of ammonia, contained in a flask, add 140 parts (3½ oz. av. or 3¾ fluidounces) of distilled water, and afterward the carbonate of ammonium reduced to a moderately fine powder. Close the flask and agitate the contents until the carbonate is dissolved. Weigh the alcohol in a tared flask of suitable capacity, add the oils, then gradually add the solution of carbonate of ammonium, and afterward enough distilled water to make the product weigh 1000 parts (25 oz. av. = 27½ fluidounces). Lastly, filter the liquid through paper in a well-covered funnel. Keep the product in glass-stoppered bottles in a cool place.—*U. S.*

Oil of nutmeg 4½ fluidrachms, oil of lemon 6½ fluidrachms, alcohol 6 pints, water 3 pints; distil 149 fluidounces. Place the last 9 oz. of distillate in a bottle with ammonium carbonate 4 oz. and strong ammonia solution 8 fl. oz.; warm gently to 140° F. until dissolved; filter through cotton and gradually mix with the distillate.—*Br.*

On adding ammonia-water to official carbonate of ammonium, neutral carbonate of ammonium is formed, which is readily soluble in alcohol. This is the compound aimed at by both pharmacopœias. If official carbonate of ammonium is treated with alcohol, neutral carbonate of ammonium will be dissolved, and bicarbonate of ammonium, being nearly insoluble, will be left behind. An insoluble saline precipitate will therefore indicate either a deficiency in the strength of the ammonia-water or a partial decomposition of the carbonate used. This salt should be employed only in translucent masses, and the effloresced portion, which contains variable proportions of bicarbonate of ammonium, should be rejected for this preparation. A. Blair (1885) has shown that oil of nutmeg is preferable to oil of pimenta, which causes the spirit to become red or brown.

Properties.—This spirit is colorless or yellowish, has an aromatic and at the same time ammoniacal odor, effervesces with acids, becomes milky on the addition of water, and has the specific gravity 0.885 *U. S.* (0.886 *Br.*).

Medical Action and Uses.—This is a mild preparation of ammonia, which is used almost exclusively for the relief of *headache*, and especially of that form of it which is attended with *acidity* of the stomach and *flatulent* eructations. It probably exerts a double action upon the stomach, neutralizing its acidity and provoking the expulsion of its gaseous contents, and upon the nervous system by a gentle stimulant action which allays nervous pain.

The *dose* of aromatic spirit of ammonia is from 30 minims to a fluidrachm (*Gm.* 2–4), properly diluted.

SPIRITUS AMMONIÆ FÆTIDUS, *Br.*—FETID SPIRIT OF AMMONIA.

Alcoolat ammoniacal fétide, Essence antihystérique, Fr.; Ammoniakalischer Stinkasandgeist, G.

Preparation.—Take of Asafetida 1½ ounces; Strong Solution of Ammonia 2 fluidounces; Rectified Spirit a sufficiency. Break the asafetida into small pieces and macerate it, in a closed vessel, in 15 fluidounces of the spirit for 24 hours; then distil off the spirit, mix the product with the solution of ammonia, and add sufficient rectified spirit to make 1 pint (Imperial).—*Br.*

On distilling the tincture of asafetida prepared as above directed, a portion of the volatile oil of asafetida passes over; the finished preparation is therefore an alcoholic solution of this volatile oil mixed with ammonia-water. *Aqua fetida antihysterica (s. Pragensis)* is a weak distilled spirit free from ammonia, but contains the volatile products of galbanum, myrrh, valerian, zedoary, angelica, peppermint, wild thyme, English chamomile, and castor, in addition to the oil of asafetida.

Medical Action and Uses.—The purpose of this preparation is to associate a special nervous stimulant with ammonia. Asafetida is often indicated where ammonia is appropriate, and especially in cases of *hysterical* derangements, whether exhibited in general nervous disorder or in that of a particular organ, as the larynx, the stomach, the bowels, or the uterus. It may be usefully associated with other antacids and with emminatives in *flatulent colic* from indigestion. The *dose* is from 30 minims to a fluidrachm (*Gm.* 2–4).

SPIRITUS ANISI, *U. S.*—SPIRIT OF ANISE.

Alcoolat d'anis, Fr.; Anisgeist, G.

Preparation.—Oil of Anise 10 parts (1 oz. av. or 1 fluidounce); Alcohol 90 parts (9 oz. av. or 10½ fluidounces); to make 100 parts (10 oz. av.). Mix them.—*U. S.*

The *essence of anise* of the British Pharmacopœia has more than twice the strength in oil of anise of the foregoing (see page 592).

Medical Uses.—Spirit of anise is used for the relief of *flatulent colic* and as a flavoring ingredient of mixtures, in the *dose* of 1 or 2 fluidrachms (Gm. 4–8).

SPIRITUS ARMORACIÆ COMPOSITUS, *Br.*—COMPOUND SPIRIT OF HORSERADISH.

Esprit de raifort composée, Alcoolat antiscorbutique, Fr.; Meerrettiggeist, G.

Preparation.—Take of Horseradish-Root, seraped, Bitter Orange-Peel, cut small and bruised, each 20 ounces; Nutmeg, bruised, $\frac{1}{2}$ ounce; Proof Spirit 1 gallon; Water 2 pints. Mix, and distil a gallon (Imperial) with a moderate heat.—*Br.*

This preparation is an alcoholic solution of the volatile oils of the drugs used.

Medical Uses.—This compound is appropriate in cases of atonic *dropsy*, especially of renal origin, but is more or less efficient in all forms of dropsy in which the use of diuretics is indicated. It may be added with advantage to various diuretic infusions, such as the compound infusion of juniper, the infusion of digitalis, etc. The *dose* is from 1 to 2 fluidrachms (Gm. 4–8).

SPIRITUS AURANTII, *U. S.*—SPIRIT OF ORANGE.

Esprit d'orange, Fr.; Orangengeist, G.

Preparation.—Oil of Orange-Peel 6 parts (300 grains or 6 fluidrachms); Alcohol 94 parts (4700 grains = $10\frac{3}{4}$ oz. av. or $12\frac{3}{4}$ fluidounces); to make 100 parts (5000 grains or about 13 fluidounces). Mix them.—*U. S.*

This has been newly introduced, and contains four times the amount of oil of orange-peel (by weight) used for the elixir of orange.

Medical Uses.—Like the tinctures of orange-peel, it is well adapted for flavoring mixtures.

SPIRITUS CAJUPUTI, *Br.*—SPIRIT OF CAJUPUT.

Alcoolat de cajeput, Fr.; Cajeputgeist, G.

Preparation.—Take of Oil of Cajuput 1 fluidounce; Rectified Spirit 49 fluidounces. Dissolve.—*Br.*

Medical Uses.—Being merely a solution of oil of cajuput in alcohol, it might be made by extemporaneous prescription. Each fluidrachm of the spirit contains $1\frac{1}{2}$ minims of the oil, and the *dose* is from half a fluidrachm to a fluidrachm (Gm. 2–4).

SPIRITUS CAMPHORÆ, *U. S., Br.*—SPIRIT OF CAMPHOR.

Alcohol camphoratus, F. P.; Spiritus camphoratus, P. G.; Tinctura camphoræ.—Tincture of camphor, E.; Esprit de camphre, Alcool camphré, Fr.; Kampferspiritus, G.

Preparation.—Camphor 10 parts (5 oz. av.); Alcohol 70 parts (35 oz. av. or 41 fluidounces); Water 20 parts (10 oz. av. or $9\frac{1}{2}$ fluidounces); to make 100 parts (50 oz. av. or about $3\frac{1}{4}$ pints). Dissolve the camphor in the alcohol, add the water, and filter through paper.—*U. S.* This is also the formula of P. G.

Take of camphor 1 ounce; rectified spirit 9 fluidounces. Dissolve.—*Br.*

Dissolve 1 part of camphor in 9 parts of alcohol.—*F. Cod.*

The present spirit contains for the same measure about two-thirds the weight of camphor as compared with that of the U. S. P. 1870.

Medical Uses.—The internal use of this preparation of camphor is seldom appropriate, chiefly because the camphor is separated immediately on coming in contact with the moisture of the mouth, fauces, etc. Externally, it is applied, as camphorated liniment is, for allaying pain in sprained, chafed, and contused parts, but it is preferable to the oily preparation whenever the local pain is *neuralgic* or is attended with inflammation, because in the latter case the evaporation of the alcohol produces a sense of coolness which is very grateful. This action is frequently invoked in bathing the mammae in order to diminish the *secretion of milk* after parturition or to assist in drying it up for weaning. Applied on cotton to an exposed nerve-pulp, it mitigates, and may quite

remove, the *toothache*. Like powdered camphor, it may be used advantageously in *hospital gangrene* and in various *ulcers* of an indolent nature.

The dose of spirit of camphor is from 5 to 30 minims (Gm. 0.30–2).

SPIRITUS CHLOROFORMI, U. S., Br.—SPIRIT OF CHLOROFORM.

Alcoolat de chloroforme, Fr.; *Chloroformspiritus*, G.

Preparation.—Purified Chloroform 10 parts (1 oz. av.); Alcohol 90 parts (9 oz. av. or 10½ fluidounces); to make 100 parts (10 oz. av. or about 11 fluidounces). Mix them.—U. S.

Chloroform 1 fluidounce; rectified spirit 19 fluidounces; dissolve.—Br.

The preparation was formerly known as *chloric ether*. Compared with that of the U. S. P. 1870, the present spirit is about 4 per cent. stronger in chloroform; the latter has been slightly reduced by the addition of a little alcohol.

Medical Uses.—This is a convenient preparation for administering chloroform by the stomach. It may be prescribed in *colic*, whether flatulent, neuralgic, or biliary, and indeed in almost all painful abdominal disorders. *Dose*, from 20 to 60 minims (Gm. 1.20–4), or more properly diluted.

SPIRITUS CINNAMOMI, U. S., Br.—SPIRIT OF CINNAMON.

Alcoolat de cannelle, Fr.; *Zimmtspiritus*, G.

Preparation.—Oil of Cinnamon 10 parts (1 oz. av. or 7½ fluidrachms); Alcohol 90 parts (9 oz. av. or 10½ fluidounces); to make 100 parts (10 oz. av.). Mix them.—U. S.

Oil of (Ceylon) cinnamon 1 fluidounce; rectified spirit 49 fluidounces.—Br.

Medical Uses.—It may be prescribed pure, in the *dose* of from 10 to 20 drops (Gm. 0.60–1.30), in cases of *colic* with diarrhœa, and as a flavoring addition to various mixtures. But for the latter purpose cinnamon-water is more commonly used.

SPIRITUS FRUMENTI, U. S.—WHISKY.

Whiskey, E.; *Eau de vie de grains*, Fr.; *Kornbranntwein*, G.

Spirit obtained from fermented grain by distillation, and containing from 44 to 50 per cent. by weight or from 50 to 58 per cent. by volume of absolute alcohol.

Origin and Preparation.—The term “whisky” is supposed to be derived from *uisque*, the first two syllables of *uisquebaugh*, the original name in Ireland—itself from Irish *uisge* and *beatha*, “life,” *Uisge beatha*, *Aqua vitæ*, “Water of life” (Dunglison’s Dictionary). In Europe whisky is often made by fermenting potatoes, but likewise from different kinds of grain; in Great Britain principally from barley, oats, and rye. In the United States rye, maize, and wheat are mostly employed for the manufacture of whisky, either in the raw state or after having been previously malted, when it furnishes a product of better flavor. The fermenting mixture is called the *mash*. During the fermentation the starch is converted into sugar, and finally into alcohol and carbonic acid gas (see page 140). The mixture is now subjected to distillation, and the weak spirit, called *low wine*, is rectified, and thus obtained stronger and less charged with fusel oil, which comes over chiefly in the last portions of the distillate. The *raw whisky* is kept in barrels or tanks for several years, during which time it acquires mellowness and is improved in flavor, doubtless in consequence of the formation of various compound ethers.

Properties.—Whisky is a spirituous liquid, usually of a yellowish or amber color, due to coloring matter and to a trace of tannin derived from the tanks in which it has been kept, and to a trace of sugar which has probably been added in the form of caramel. The density of whisky depends on the percentage of alcohol, and is to a slight extent influenced by the amount of the coloring and extractive matters; it should be not above .930, nor below .917. The disagreeable odor of raw whisky is mainly owing to a small quantity of amylie alcohol, which on keeping is changed into an ether, and perhaps partly into valerianic acid; cœnanthylie and other allied acids are likewise present to a slight extent. Old whisky has a slight acid reaction, due to the formation of a minute quantity of acetic acid, according to Kappel (1859), of valerianic acid. For neutralizing the acidity of good whisky 20 Ccm. require usually between 0.8 and 1.0 Ccm. of $\frac{1}{10}$ normal solution of alkali, indicating between 0.113 and 0.142 Gm. of acetic acid or its equivalent. The acidity slowly increases with age up to a certain degree; in one case 2.25 Ccm. of $\frac{1}{10}$ normal alkali were required for 20 Ccm. of whisky. For medicinal use

whisky should be free from disagreeable odor and be not less than two years old.—*U. S.*

Tests.—On evaporating whisky by a moderate heat nearly to dryness, the residue which is left should have a slightly aromatic and rather insipid, but not an acrid, taste. The most convenient test for recognizing the origin of whisky is that proposed by Molnar. A small quantity of it is heated with a slight excess of caustic potassa until the alcohol has been completely evaporated; the compound ethers are thereby decomposed, and on adding an excess of sulphuric acid the volatile acids are liberated, and from their odor the source is recognized. *Apple whisky* distilled from cider gives off a decided fruit odor; the odors of whiskies of different kinds of grain are sufficiently distinct from one another, but to readily recognize them considerable experience is required. "If 100 Ccm. of whisky be very slowly evaporated in a weighed capsule on a water-bath, the last portions volatilized should not have a harsh or disagreeable odor (absence of more than traces of fusel oil from grain or potato spirit). The remaining residue, fully dried at 100° C. (212° F.), should weigh not more than 0.233 Gm., equivalent to 0.25 per cent. (absence of an undue amount of solids). This residue should have no sweet or distinctly spicy taste (absence of added sugar, glycerin, or spices). It should nearly all dissolve in 10 Ccm. of cold water, forming a solution which is colored light-green by a dilute solution of ferric chloride (traces of oak tannin from casks). 100 Ccm. of whisky should be rendered distinctly alkaline to litmus by 2 Ccm. of the volumetric test solution of soda (absence of an undue amount of free acid)."—*U. S.*

Medical Action and Uses.—Whisky has probably been made official because genuine brandy of good quality is not readily procured. It is one of the unfounded claims of science that bodies of apparently the same composition are identical in their action, for experience daily shows that physiological effects cannot be predicted upon chemical grounds alone. The action of whisky, both immediate and remote, differs in many respects from that of brandy, and the former liquor made from rye is not identical with that distilled from wheat, nor are potato brandy and grape brandy alike in their effects. Whisky, and also gin, besides being less palatable to all but the coarsest tastes than brandy, are much more apt than the latter to produce functional and then organic disease of the stomach, liver, and kidneys, and their immediate operation is less genial and exhilarating. In the absence of pure brandy, whisky is probably the best of the alcoholic distilled liquors, since its comparative cheapness in a great measure removes the temptation of dealers to adulterate it. The proper occasions and indications for its medicinal use, both internal and external, are described under ALCOHOL.

SPIRITUS GAULTHERIÆ, *U. S.*—SPIRIT OF GAULTHERIA.

Preparation.—Oil of Gaultheria 3 parts (90 grains or 80 minims); Alcohol 97 parts (2910 grains = 6½ oz. av. or 7¾ fluidounces); to make 100 parts (3000 grains or about 8 fluidounces). Mix them.—*U. S.*

"Essence of wintergreen" has been in use for a long time, but was prepared of varying strength. The pharmacopœial formula is intended to accomplish uniformity.

Medical Uses.—This preparation is more convenient than the oil of gaultheria for giving an agreeable flavor to medicinal preparations.

SPIRITUS JUNIPERI, *U. S., Br.*—SPIRIT OF JUNIPER.

Alcoolat (Esprit) de genévre, Fr.; Wachholdersspiritus, G.

Preparation.—Oil of Juniper 3 parts (90 grains or 110 minims); Alcohol 97 parts (2910 grains = 6½ oz. av. or 7¾ fluidounces); to make 100 parts (3000 grains or about 8 fluidounces). Mix them.—*U. S.*

Oil of juniper 1 fluidounce; rectified spirit 49 fluidounces; dissolve.—*Br.*

Macerate for 24 hours 5 parts of bruised juniper-berries with 15 parts each of alcohol and water, and distil 20 parts.—*P. G.*

The present spirit is one-third stronger than that of the *U. S. P.* 1870. If made from the volatile oil distilled from juniper-berries, it is much more agreeable than if the common oil of juniper is used. Age improves the flavor.

Off. Prep.—Mistura creasoti, *Br.*

Medical Action and Uses.—This preparation is carminative and diuretic, and is useful as an addition to infusions and mixtures employed in the treatment of *dropsy*. Its dose is from 30 to 60 minims (Gm. 2-4).

SPIRITUS JUNIPERI COMPOSITUS, U. S.—COMPOUND SPIRIT OF JUNIPER.

Preparation.—Oil of Juniper 10 parts (30 grains or 37 minims); Oil of Caraway 1 part (3 grains or 3 minims); Oil of Fennel 1 part (3 grains or 3 minims); Alcohol 3000 parts (9000 grains = 20½ oz. av. or 24½ fluidounces); Water a sufficient quantity; to make 5000 parts (15,000 grains). Dissolve the oils in the alcohol, and gradually add enough water to make the product weigh 5000 parts (15,000 grains = 34½ oz. av. or about 36 fluidounces).—*U. S.*

This spirit is an official substitute for *gin*, a spirit distilled in some parts of Europe from juniper-berries, to which sometimes other aromatics are added. It has the advantage of uniformity of composition over the commercial article, and if good volatile oils are used the flavor is agreeable and will improve by age.

Medical Action and Uses.—The addition of caraway and fennel oils to that of juniper in this compound increases the virtues it derives from the last-named ingredient, and especially gives it a carminative operation, which is often called for in abdominal *dropsy*; for in that disease the abdominal and intestinal walls lose their contractile power and become distended by the gases formed in the cavity of the bowel. It is commonly added to diuretic infusions. The *dose* is from 1 to 4 fluidrachms (Gm. 4–16).

SPIRITUS LAVANDULÆ, U. S., Br.—SPIRIT OF LAVENDER.

Alcoolat (Esprit, Eau) de lavande, Fr.; Lavendelspiritus, G.

Preparation.—Oil of Lavender-Flowers 3 parts (90 grains or 107 minims); Alcohol 97 parts (2910 grains = 6½ oz. av. or 7¾ fluidounces); to make 100 parts (3000 grains or about 8 fluidounces). Mix them.—*U. S.*

Oil of lavender 1 fluidounce; rectified spirit 49 fluidounces; dissolve.—*Br.*

Macerate for 24 ounces lavender-flowers 5 parts, with alcohol and water each 15 parts, and distil 20 parts.—*P. G.*

For use as a perfume a small quantity of oil of bergamot, tincture of musk, or tincture of ambergris is sometimes added, the addition of the tincture being made to the distilled spirit.

Off. Prep.—Mistura ferri comp., *U. S.*

Medical Action and Uses.—Spirit of lavender—or, as it is commonly called, lavender-water—is more generally used as an agreeable and refreshing perfume than as a medicine. It is popularly employed to bathe the forehead, etc. in cases of *headache*, *fever*, etc. It may be given internally in *doses* of from 30 to 60 minims (Gm. 2–4).

SPIRITUS LIMONIS, U. S.—SPIRIT OF LEMON.

Essence of lemon, E.—Alcoolat (Esprit) de citron, Fr.; Citronenessenz, G.

Preparation.—Oil of Lemon 6 parts (420 grains or 1 fluidounce and 40 minims); Lemon-Peel, freshly grated, 4 parts (280 grains or ¾ oz. av.); Alcohol a sufficient quantity; to make 100 parts (7000 grains or 16 oz. av.). Dissolve the oil of lemon in 90 parts (6300 grains = 14½ oz. av. or 16½ fluidounces) of alcohol, add the lemon-peel, and macerate for 24 hours; then filter through paper, adding through the filter enough alcohol to make the spirit weigh 100 parts (16 oz. av. or 18¾ fluidounces).—*U. S.*

Macerate for 2 days 500 parts of fresh rind of lemon with 3000 parts of 80 per cent. alcohol, and distil until all the alcohol has passed over.—*F. Cod.*

Off. Prep.—Syrupus acidi citrici, *U. S.*

Medical Uses.—This preparation is only used for flavoring simple syrup and medicinal mixtures.

SPIRITUS MENTHÆ PIPERITÆ, U. S., Br., P. G.—SPIRIT OF PEPPERMINT.

Essence of peppermint, E.; Alcoolat (Essence) de menthe poivrée, Fr.; Englische Pfefferminzessenz, G.

Preparation.—Oil of Peppermint 10 parts (600 grains or 12 fluidrachms and 38 minims); Peppermint, in coarse powder, 1 part (60 grains); Alcohol a sufficient quantity; to make 100 parts (6000 grains). Dissolve the oil of peppermint in 90 parts (5400 grains = 12½ oz. av. or 14½ fluidounces) of alcohol, add the peppermint, and macerate

for 24 hours; then filter through paper, adding through the filter enough alcohol to make the spirit weigh 100 parts (6000 grains = $13\frac{3}{4}$ oz. av. or 16 fluidounces).—*U. S.*

Oil of peppermint 1 fluidounce; rectified spirit 49 fluidounces; dissolve.—*Br.*

The U. S. P. 1870 ordered the oil and alcohol very nearly in the proportion of 7 : 100; the present formula yields a preparation fully 40 per cent. stronger. The formula of the P. G. agrees with the above, except that the spirit is not colored. The spirit of the Br. P. is one-fifth, but the essentia (see p. 592) is about double, the strength of the above.

Off. Prep.—Mistura rhei et sodæ, *U. S.*

Medical Uses.—This preparation is the most convenient form for the ordinary administration of peppermint. The *dose* of the American preparation is from 5 to 15 drops (Gm. 0.30–1), taken on loaf sugar or in sweetened water. The *dose* of the British spirit is from $\frac{1}{2}$ to 1 fluidrachm (Gm. 2–4).

SPIRITUS MENTHÆ VIRIDIS, *U. S.*—SPIRIT OF SPEARMINT.

Essence of spearmint, E.

Preparation.—Oil of Spearmint 10 parts (600 grains or 12 fluidrachms and 38 minims); Spearmint, in coarse powder, 1 part (60 grains); Alcohol a sufficient quantity; to make 100 parts (6000 grains). Dissolve the oil of spearmint in 90 parts (5400 grains = $12\frac{3}{4}$ oz. av. or $14\frac{1}{2}$ fluidounces) of alcohol, add the spearmint, and macerate for 24 hours; then filter through paper, adding through the filter enough alcohol to make the spirit weigh 100 parts (6000 grains = $13\frac{3}{4}$ oz. av. or 16 fluidounces).—*U. S.*

The strength of this spirit has been increased like that of the preceding one. The analogous preparation used in France is distilled from fresh crisped mint, and that used in Germany as *Englische Krauseminzessenz* is made by dissolving 1 part of oil of crisped mint in 9 parts (by weight) of alcohol.

Medical Uses.—This preparation is less energetic than that of peppermint. It may be given in the *dose* of from 20 to 40 minims (Gm. 1.30–2.60).

SPIRITUS MYRCIÆ, *U. S.*—SPIRIT OF MYRCIA.

Bay-rum, E.

Preparation.—Oil of Myrcia 16 parts (320 grains or $5\frac{1}{2}$ fluidrachms); Oil of Orange-Peel 1 part (20 grains or $2\frac{1}{4}$ minims); Oil of Pimento 1 part (20 grains or 20 minims); Alcohol 1000 parts (20,000 grains = 2 pounds $13\frac{3}{4}$ oz. av. or $53\frac{1}{2}$ fluidounces); Water 782 parts (15,640 grains = 2 pounds $3\frac{3}{4}$ oz. av. or $34\frac{1}{4}$ fluidounces); to make 1800 parts (36,000 grains = 5 pounds $2\frac{1}{2}$ oz. av. or $5\frac{1}{2}$ pints). Mix the oils with the alcohol, and gradually add the water to the solution. Set the mixture aside, in a well-stopped bottle, for 8 days; then filter through paper in a well-covered funnel.—*U. S.*

On diluting an alcoholic solution of volatile oils rapidly with water a milkiness is apt to be produced, which is subsequently not readily removed by agitation; it is therefore directed to add the water gradually, so that the appearance of a permanent milkiness may be avoided as much as possible. If after a week the spirit cannot be decanted or filtered clear, it may be treated with paper-pulp or other material (except cotton-fibres) usually used in the preparation of medicated waters.

Bay-rum is distilled in several of the West Indian islands from the fresh leaves of *Myrcia acris* (see p. 1072), to which a certain proportion of the fruit is added, St. Croix rum being used for the best quality; its flavor is affected by the employment of the leaves of different varieties of the plant, or probably of different closely-allied species of myrtles. (See paper by A. H. Riise in *Amer. Jour. Phar.*, 1882, p. 278.) However, most of the bay-rum consumed in the United States is now manufactured here, a small portion being distilled from the dried leaves. The pharmacopœial formula furnishes a preparation of agreeable fragrance and of a pale-yellowish color or nearly colorless.

Medical Uses.—Bay-rum, like lavender-water, is used exclusively as a perfume and as a refreshing application to the forehead in *headache* and to other parts irritated by heat or chafing.

SPIRITUS MYRISTICÆ, *U. S., Br.*—SPIRIT OF NUTMEG.

Alcoolat (Esprit) de muscade, Fr.; Muskatspirit, G.

Preparation.—Oil of Nutmeg 3 parts (90 grains or 104 minims); Alcohol 97 parts (2910 grains = $6\frac{1}{2}$ oz. av. or $7\frac{3}{4}$ fluidounces); to make 100 parts (3000 grains or about 8 fluidounces). Mix them.—*U. S.*

Take of volatile oil of nutmeg 1 fluidounce; rectified spirit 49 fluidounces; dissolve.—*Br.*

In France this spirit is prepared by macerating for 4 days 500 parts of bruised nutmeg with 4000 parts (by weight) of 80 per cent. alcohol, and distilling as long as alcohol passes over.

Off. Prep.—Mistura ferri comp., *Br.*

Medical Uses.—Spirit of nutmeg is used as a flavoring ingredient, but less commonly than other aromatics. Its *dose* is from $\frac{1}{2}$ to 1 fluidrachm (Gm. 2–4).

SPIRITUS ODORATUS, U. S.—PERFUMED SPIRIT.

Spiritus (Aqua) coloniensis. Alcoolatum fragrans.—*Cologne-water, E.; Eau de Cologne, Alcoolat de citrons composé, Fr.; Kölnisches Wasser, G.*

Preparation.—Oil of Bergamot 16 parts (2 oz. av. or $17\frac{1}{2}$ fluidrachms); Oil of Lemon 8 parts (1 oz. av. or 9 fluidrachms); Oil of Rosemary 8 parts (1 oz. av. or $8\frac{1}{2}$ fluidrachms); Oil of Lavender-Flowers 4 parts ($\frac{1}{2}$ oz. av. or $4\frac{1}{4}$ fluidrachms); Oil of Orange-Flowers 4 parts ($\frac{1}{2}$ oz. av. or $4\frac{1}{2}$ fluidrachms); Acetic Ether 2 parts ($\frac{1}{2}$ oz. av. or $2\frac{1}{4}$ fluidrachms); Water 158 parts (19 $\frac{3}{4}$ oz. av. or 19 fluidounces); Alcohol 800 parts (100 oz. av. or 7 pints 5 fluidounces); to make 1000 parts (125 oz. av. or $8\frac{1}{2}$ pints). Dissolve the oils and the acetic ether in the alcohol, and add the water. Set the mixture aside, in a well-closed bottle, for 8 days, then filter through paper in a well-covered funnel.—*U. S.*

The formula of the French Codex is similar. This spirit should be kept on hand for some time, when its fragrance will improve.

Medical Uses.—Cologne-water would seem to pertain to the perfumer rather than to the pharmacist or physician, and therefore to be quite misplaced in a pharmacopœia.

SPIRITUS ROSMARINI, *Br.*—SPIRIT OF ROSEMARY.

Spiritus anthos.—*Alcoolat (Esprit) de romarin, Fr.; Rosmarinspiritus, G.*

Preparation.—Take of Oil of Rosemary 1 fluidounce; Rectified Spirit 49 fluidounces; dissolve.—*Br.*

The preparation known in Europe, and formerly much employed, as *Aqua regina Hungarica* (Eau de la reine de Hongrie, *Fr.*), is a compound spirit of rosemary, usually containing a little lavender, sage, or other aromatic oil.

Medical Action and Uses.—This preparation is but little used in the United States. It is worthy of being more generally employed, not only for its perfume, which is very grateful to most persons, but as a stimulant in nervous and hysterical conditions, and locally for the relief of muscular and neuralgic pains. Like the oil of rosemary, it may be added to stimulating and anodyne liniments. Each fluidrachm (Gm. 4) of the spirit contains nearly 1 minim of the oil.

SPIRITUS TENUIOR, *Br.*—PROOF SPIRIT.

Preparation.—Take of Rectified Spirit 5 pints; Distilled Water 3 pints; mix.—*Br.* It has the specific gravity 0.920 (see page 142).

Medical Uses.—This form of alcohol is employed in medicine only as a lotion for contusions, rheumatic pains, etc.

SPIRITUS VINI GALLICI, U. S., *Br.*—BRANDY.

Spiritus vini Cognac, P. G.—*Spirit of French wine, E.; Eau de vie, Cognac, Fr.; Franzbranntwein, G.*

The spirit obtained from fermented grapes by distillation, and containing from 39 to 47 per cent. by weight or 46 to 55 per cent. by volume of absolute alcohol.

Origin and Preparation.—Brandy is made in France by distilling different kinds of wine. The colorless spirit (*white brandy*) thus obtained is kept for some time in new oak casks, where it gradually acquires a light-amber tint (*pale brandy*). The darker-colored varieties have their color deepened by the addition of caramel. The brandies obtained in different districts of France are not esteemed alike, those of Cognac and

Armagnac being deemed the best, owing to the agreeable mildness of their flavor; next in order are those from Bordeaux and Rochelle. The lees of wines and the marc of grapes are also distilled, and furnish a spirituous liquid called in France *eau de vie de marc*, which is highly charged with odorous principles, and is used as an addition to other brandies and for imitating brandy by mixing the liquid with pure rectified spirit. The odorous constituents separated from all or most of the alcohol are sometimes met with in commerce as *oil of grapes*. Large quantities of brandy are also distilled in Spain and Portugal, and of recent years in Germany.

Considerable brandy is now made in the United States, and is usually distinguished as Catawba and California brandy. *Catawba brandy* is made in the vine-growing districts of the Ohio and Mississippi Valley, according to E. S. Wayne (1855), from the lees and from the marc. That made from the lees is the best, and has the flavor of Catawba wine. When distilled from the marc it has an unpleasant taste, and contains a large amount of fusel oil, but is mellowed down by age. *California brandy* is made from the lees and marc, which are thrown together with poor wines and distilled, the distillate being tinged by the addition of caramel (*Proc. Amer. Phar. Assoc.*, 1866, p. 64).

The British Pharmacopœia recognizes only the spirit of French wine, while the U. S. and German Pharmacopœias admit all spirits obtained from fermented grapes or wine, without designating French wine.

Properties.—Brandy is a spirituous, amber-colored liquid having a peculiar flavor, which is improved by age; hence the U. S. P. directs it to be used only when at least four years old. The flavor depends upon the variety of grapes used, upon their ripeness, upon the care bestowed upon fermentation and distillation, and upon the age of the wine, an older wine yielding a more fragrant distillate. The specific gravity of brandy is required to be between .925 and .941 U. S. (between .920 and .924, corresponding to between 46 and 50 per cent. by weight of alcohol, *P. G.*). It has a slight acid reaction, which is, at least in part, due to the presence of acetic acid. The P. G. states that the distillate should not be acid; it has, however, a faint acid reaction, though not an acidulous taste. We have found good brandy to require for the neutralization of 20 Cem. from 1.3 to 1.7 Cem. of $\frac{1}{10}$ normal alkaline solution, indicating from .185 to .241 Gm. of free acetic acid in the pint. The odor is due to minute quantities of cœnanthic, acetic, and perhaps propylic and allied ethers; its quality is best ascertained by pouring some of the brandy into a wine-glass, then emptying the latter, and, without washing or wiping it, setting it aside; the peculiar fragrance becomes then more apparent, and is still noticeable after a day, while the odor of brandy which had been diluted with deodorized spirit becomes weak and disappears in the course of a few hours, during which time also the odor of whisky or similar spirits becomes apparent. Brandy assumes a dark-greenish color on the addition of ferric chloride, owing to the presence of tannin derived from the casks or from catechu, etc., purposely added. Sugar can usually be detected in the extract by Trommer's test, and is derived from caramel.

Tests.—The addition of grains of paradise, Cayenne pepper, and similar substances, sometimes used for imparting artificial strength to brandy, is detected by the sharp or burning taste of the extract left on evaporation. With sufficient practical experience the origin of brandy may be recognized by Molnar's method (see SPIRITUS FRUMENTI), but it is more difficult to distinguish, by their odors, the ethers and fusel oils of the French wines used for making brandy than the fusel oils of different kinds of grain. "If 100 Cem. of brandy be very slowly evaporated in a weighed capsule on a water-bath, the last portion volatilized should have an agreeable odor, free from harshness (absence of fusel oil from grain or potato spirit). The residue, dried at 100° C. (212° F.), should weigh not more than 0.235 Gm., equivalent to 0.25 per cent. (absence of an undue amount of solids). This residue should have no sweet or distinctly spicy taste (absence of added sugar, glycerin, or spices). It should nearly all dissolve in 10 Cem. of cold water, forming a solution which is colored light-green by a dilute solution of ferric chloride (traces of oak tannin from casks). 100 Cem. of brandy should be rendered distinctly alkaline to litmus by 3 Cem. of the volumetric solution of soda (absence of an undue amount of free acid)."—U. S.

Off. Prep.—Mistura spiritus vini gallici, *Br.*

Medical Action and Uses.—The virtues of brandy have been set forth in the article on ALCOHOL. It may be sufficient here to repeat that true brandy—that is, made from wine—has qualities peculiar to itself and unlike those belonging to other distilled spirits. It is not only more palatable, but more cordial to the stomach and produces a more grateful exhilaration.

SPONGIA.—SPONGE.

Eponge, Fr.; *Schwamm*, *Badeschwamm*, G.

Spongia officinalis, Linné.

Class Poriphera. Ord. Ceratospongiæ.

Origin and Description.—Sponges belong to the lowest animals which live in water, and are attached to rocks or other substances. They consist of a framework arising from a broad base and forming a ramifying and anastomosing tissue, which is traversed by numerous canals and pores and covered with a glairy or gelatinous substance. In some genera the skeleton is formed, to a greater or less extent, of siliceous or calcareous spicules; in others the whole body consists of a gelatinous substance. The sponges which are in common use belong to a few species, the skeleton of which is entirely or nearly free from spicules, and forms cup-shaped or convex, porous, and lacunose masses, with circular vents on the surface. They are collected by divers, who tear them from the rocks, or they are detached by means of a fork fastened to the end of a long pole. The gelatinous animal matter is removed by burying them for several days in sand, and afterward soaking, squeezing, and washing them.

The best variety of sponge comes from the Mediterranean, and is chiefly collected in the neighborhood of Greece and near the coast of Syria. It is known in commerce as *Mediterranean* and *Turkish sponge*, and comes in cup-shaped pieces of various sizes, having a soft, elastic, and compressible fibrous framework. The *Bahama* or *West Indian sponge* is collected near the Bahama Islands, and forms convex or oblong pieces, with somewhat projecting lobes and of a coarser texture than the preceding. As met with in commerce, sponge generally contains a large quantity of sand, from which it is freed by beating, and various calcareous matters, which are removed mechanically or by dissolving them with the aid of dilute hydrochloric acid. After it has been cleaned it is sometimes *bleached*, either by means of solution of sulphurous acid prepared from hyposulphite of sodium and hydrochloric acid or preferably by chlorine-water. A still better process is dipping the sponge for five or ten minutes into a 2 per cent. solution of potassium permanganate, and subsequently immersing it in a 2 per cent. solution of oxalic acid to which a little sulphuric acid has been added; the latter treatment removes the brown manganic oxide and leaves the sponge white, without affecting its durability.

Composition.—The organic matter of sponge is a proteid called *spongin*, which was formerly supposed to be closely allied to, or identical with, *fibroin* or *sericin* of silk, but was proven by Schlossberger (1858) and Staedeler (1859) to be entirely distinct, in being insoluble or very slowly soluble in ammoniacal solutions of the oxides of nickel and copper, and in the behavior to hot diluted sulphuric acid, with which it yields *leucin* and *glycocoll*, while sericin yields by this treatment tyrosin and serin, and is readily dissolved by solutions of nickel and copper in ammonia. Spongin is soluble in hot solution of caustic potassa and in hot mineral acids.

Derivatives and Allied Product.—SPONGIA USTA, *Burnt sponge*, is obtained by heating clean sponge, cut into small pieces, in a closed vessel until vapors cease to be given off. The residue amounts to about one-third the weight of the sponge, and consists of about 40 per cent. of charcoal, 25 to 30 per cent. of sulphate of calcium, 10 per cent. of silica, 9 per cent. of ferrous oxide, the remainder being magnesium carbonate, potassium chloride, and calcium phosphate, and about $\frac{1}{2}$ of 1 per cent. of sodium iodide (Herberger).

SPONGIE CERATÆ.—Sponge tent, *E.*: *Eponge préparée à la cire*, Fr.; *Wachsschwämme*, G.—Sponge is freed from foreign matters by heating and washing, then dried, cut into proper shape, dipped into yellow melted wax, pressed between hot iron plates, and when cold freed from the excess of wax.

SPONGIE COMPRESSÆ.—Compressed sponge, *E.*: *Eponge préparé à la ficelle*, Fr.; *Pressschwamm*, G.—Perfectly clean, fine sponge is cut into elongated pieces while moist, securely tied by means of twine into cylindrical pieces, and then dried.

VEGETABLE SPONGE, or GOURD TOWEL. The fibrous network of the fruit of *Luffa ægyptiaca*, Miller (Momordica luffa, Linné; nat. ord. Cucurbitaceæ), has been used to some extent, under these and similar names, like a sponge and flesh-brush. *Luffa Petola*, Seringe, and *L. foetida*, Cavanilles, yield similar products. The fleshy portion of these fruits is edible, though not very palatable; several other species are violently purgative and emetic.

Medical Action and Uses.—Before the discovery of iodine, roasted or so-called "burnt" sponge was generally used in the treatment of *goitre*, both internally and externally, and certainly with excellent results in appropriate cases; but it is now wholly superseded by the preparations of iodine. Sponge is familiarly employed for countless domestic purposes which require the use of a porous, compressible, and elastic substance

capable of holding liquids, and, amongst others, for partial or general baths, which are of such great hygienic importance. Its use in medicine and surgery for absorbing blood, pus, and other animal liquids is equally familiar, and not less so are the dangers to which it exposes the patients in hospitals by carrying from one to another the germs of infectious diseases. Sponges that have been used in surgical operations and dressings should never be dried before being thoroughly purified with boiling water. The elasticity of sponge renders it an efficient means of dilating wounds, sinuses, the natural apertures of the body, etc. For this purpose it should be introduced in a dry and compressed state, when, by absorbing the liquids of the part, it gradually expands with irresistible force. To promote its introduction into narrow canals, such as that of the neck of the uterus, compressed sponge, saturated or merely coated with wax, is of the greatest utility. (Compare A. Smith, *Med. News*, xl. 197.) It is used to dilate wounds, etc. in order to facilitate the extraction of foreign bodies or the discharge of secretions, as well as the introduction of probes, forceps, and other surgical instruments. In the cervix uteri it is employed to relieve *dysmenorrhœa* and also to induce *premature labor*. Sometimes the sponge, before being compressed and coated with wax, is saturated with a solution adapted to stimulate or otherwise modify the condition of the part.

STANNUM.—TIN.

Etain, Fr.; *Zinn*, G.

Symbol Sn. Atomicity bivalent and quadrivalent. Atomic weight 117.7.

Origin and Preparation.—Tin is rarely found in the metallic state. Its most important ore is a binoxide, SnO_2 , known as *tinstone*, which is usually imbedded in granite, quartz, or slate, and often associated with iron pyrites and with tungstate of iron and manganese, known as the mineral *wolfram*. It is rarely met with as silicate, and is present in *columbite*, *tantalite*, and allied minerals, and in minute proportions in the mineral waters of Saldschütz and other places. The most important tin-mines are in Devonshire and Cornwall in Great Britain and in Malacca and Banca, but tin is likewise obtained in Australia, Bohemia, Saxony and some parts of the United States. Australian tin sometimes contains gold. The tinstone is stamped into a coarse powder, freed from lighter minerals by washing with a stream of water, roasted to expel arsenic and sulphur, again washed with water, mixed with powdered coal and a little lime or fluor-spar for the purpose of forming a fusible slag, and then reduced on the hearth of a reverberatory furnace.

Properties.—Tin is a bluish-white metal of the specific gravity 7.3, softer than gold, but harder than lead, and when bent emitting a crackling sound. It may be rolled or hammered into *foil*, at 100°C . (212°F .) drawn into wire, and at 200°C . (392°F .) is so brittle that it may be readily reduced to powder. It melts near 230°C . (446°F .), and, according to Nies and Winkelmann (1882), on congealing increases in volume 0.7 per cent. While cooling it is readily converted into powder by trituration in a hot iron mortar; after sifting it constitutes *Stanni pulvis*, which was formerly employed. It is but superficially oxidized in moist air, and will effectually protect iron from rusting as long as the coating is perfect. Its alloy with lead forms *pewter*, *Britannia metal*, and *solder*; alloyed with copper it constitutes *gun-metal* and *bronze*; and by combining 4 parts of tin with 3 of cadmium, 8 of lead, and 15 of bismuth a fusible alloy is obtained melting at 60°C . (140°F .).

Metallic tin dissolves in hot strong sulphuric acid to stannic sulphate, evolving sulphurous acid gas. Strong hydrochloric acid dissolves it to stannous chloride, and nitromuriatic acid yields with it stannic chloride. *Stannous salts* are precipitated brown by sulphuretted hydrogen, the precipitate being soluble in ammonium sulphhydrate. Chloride of gold produces a deep-purple precipitate (*purple of Cassius*), and mercuric chloride is reduced either to calomel or to a gray powder of metallic mercury. This reaction explains the value of stannous chloride as a test for salts of mercury. *Stannic salts*, of which the chloride, SnCl_4 , is used by dyers, do not react with the chlorides of gold and mercury, but yield with sulphuretted hydrogen a yellow precipitate which is soluble in ammonium sulphhydrate. *Sodium stannate*, $\text{Na}_2\text{SnO}_3 \cdot 4\text{H}_2\text{O}$, is used by calico-printers as a mordant, and is prepared on the large scale by fusing tin ore with soda and sodium nitrate or by boiling it with caustic soda. Both stannous and stannic salts are precipitated white by caustic potassa; the precipitates are soluble in an excess of potassa, and the alkaline solution, when obtained from stannous salts, yields on boiling a black precipitate of stannous oxide. Of the sulphides, *stannic sulphide*, SnS_2 , is of interest; it is made by heat-

ing a mixture of tin amalgam, sulphur, and sal ammoniac, when it remains behind in golden-yellow scales, ammonium chloride and sulphide and chloride of mercury subliming; when ground, stannic sulphide is known as *mosaic gold* and *bronze powder*.

Medical Action and Uses.—Since the time of Paracelsus, at least, tin filings have been used as a remedy for *tapeworms*, and a list of eminent physicians might be given, including some of the most distinguished helminthologists, who vaunted their efficacy and recommended their use. Their testimony may certainly be taken to qualify the judgment of Küchenmeister when he writes: "Once for all, I protest against the administration of tin filings, and I believe that no one can have much pleasure in giving this remedy who has seen the ecchymotic irritation of the intestine after its administration to living animals, and heard them whining or seen them writhing about during life." Even if this criticism were admitted to be just, it would not affect the question of the efficacy of the powdered metal or of tin prepared by precipitation from its chloride. The eminent authority above mentioned admits it to be real. When tin filings were employed they were supposed to act mechanically, subjecting the worms to such rude attrition as to destroy them; but since the salts of tin have sometimes proved to be taniacide, and since precipitated tin has had a like effect, it is more probable that some inherent quality of the metal must be invoked to explain its operation. Moreover, it is stated upon good authority that in certain rural districts of France it is customary to use, as a vermifuge, sweetened wine that has been kept for 24 hours in a tin vessel. The activity of the salts of tin is illustrated by the experiments of White (*Archiv. f. Exp. Path. etc.*, xiii. 53). They were seen to act upon the digestive canal and upon the central nervous system, in the former producing the symptoms and lesions of irritant poisons, and in the latter paralysis. The urine was diminished and its specific gravity increased, and it contained albumen. The author assimilates tin with lead in its action on the animal economy.

Formerly, tin filings were administered in the *dose* of 20 grains, gradually increased to $\frac{1}{2}$ ounce (Gm. 1.30–16). Powder of tin may be prescribed in the *dose* of about 1 drachm (Gm. 4). These preparations should be given in a syrup or electuary, and after the bowels have been completely cleansed by a purgative. The bisulphuret of tin has also been used as a taniacide, in doses of from 2 to 4 drachms (Gm. 8–16), in the same manner as the metal. Chloride of tin has been employed for the same purpose, "as an anti-spasmodic in epilepsy, chorea, and other convulsive diseases, as a stimulant to paralyzed muscles in paraplegia, as an antidote in poisoning by corrosive sublimate, and as an internal application in chronic skin diseases" (Pereira). It was administered internally in the *dose* of $\frac{1}{16}$ to $\frac{1}{2}$ grain (Gm. 0.004–0.03), and in an aqueous solution prepared by dissolving $\frac{1}{6}$ grain in an ounce (Gm. 0.01 in Gm. 32) of water. It acts topically as an astringent, irritant, and caustic, and in poisonous doses causes convulsions and sometimes paralysis.

STAPHISAGRIA, U. S.—STAPHISAGRIA.

Staphisagriae semina, Br.; *Semen staphisagriae*, s. *staphidis agriae*, s. *pedicularis*.—*Stavesacre*, E.; *Staphisaigre*, Fr.; *Stephanskörner*, *Läusekörner*, G.

The seed of Delphinium Staphisagria, *Linné*, s. *Staphisagria macrocarpa*, *Spach*. Bentley and Trimen, *Med. Plants*, 4.

Nat. Ord.—Ranunculaceæ, Helleboreæ.

Origin.—This annual pubescent herb is indigenous to the countries bordering on the Mediterranean, and is cultivated in some parts of Southern Europe. It attains a height of about 40 inches (1 M.), and has alternate, long-petioled, palmately five- to nine-parted leaves, the lobes being lanceolate and entire or three-lobed. The pale-blue or purplish flowers are long-peduncled, arise from the axils of leafy bracts, have two of the petals spurred, both spurs being enclosed in that of the calyx, and produce three hairy follicles, each containing about twelve seeds. The unpleasantly odorous plant (and particularly the seeds) has been employed from an early period.

Description.—Stavesacre-seeds are from $\frac{1}{8}$ to $\frac{1}{4}$ inch (4–6 Mm.) long and $\frac{1}{8}$ to $\frac{1}{4}$ inch (3–5 Mm.) broad, acutely angled and irregularly flattish-tetrahedral, one side being somewhat convex. The brittle testa is at first of a brown or blackish-brown, afterward of a brownish-gray, color, wrinkled and pitted with flattish depressions, the intervening ridges forming net-like meshes. The nucleus is whitish, when old brownish, and consists of an oily albumen enclosing at its sharper end a small straight embryo. The seeds have a faint somewhat narcotic odor and a bitter, burning, and biting taste.

Constituents.—Marquis (1877) isolated four optically inactive alkaloids—delphinine,

$C_{22}H_{33}NO_6$; delphinoidine, $C_{42}H_{63}N_2O_7$; delphisine, $C_{27}H_{46}N_2O_4$; and staphisagrine, $C_{22}H_{33}NO_5$. *Delphisine* was discovered in 1819 by Lassaigne and Feneulle, and simultaneously by Brandes. It is nearly insoluble in water, dissolves at $20^\circ C.$ ($68^\circ F.$) in 21 parts of alcohol, 11 parts of ether, and 16 parts of chloroform, crystallizes in flat prisms, has a bitter taste, followed by persistent tingling, is precipitated by the group reagents, but gives no characteristic color reaction; it does not melt at $120^\circ C.$ Studer (1872) found it to melt at $90^\circ C.$ ($194^\circ F.$), and to dissolve with a reddish color in sulphuric acid containing a trace of iron. *Delphinoidine* is amorphous, melts between 110° and $120^\circ C.$ (230° and $248^\circ F.$), dissolves in 6500 parts of water, in 3 parts of ether, and is freely soluble in chloroform and alcohol. Its characteristic reactions are with sulphuric acid dark-brown, red-brown; with Fröhde's reagent, dark-brown, blood-red, cherry-red; with sugar and sulphuric acid, brown, green; with sulphuric acid and bromine-water, violet-red, cherry-red, blood-red. *Delphisine* resembles the preceding in solubility and behavior, but forms wart-like crystals and contains more nitrogen. *Staphisagrine* or *staphisatine* was first obtained by Couërbe (1833), and Dardel's *staphisine* (1864) seems to be identical with it. It melts at $90^\circ C.$ ($194^\circ F.$), dissolves at $15^\circ C.$ ($59^\circ F.$) in 200 parts of water, in 855 parts of ether, and is very freely soluble in alcohol and chloroform; its characteristic reactions are with sulphuric acid faintly cherry-red, violet; with Fröhde's reagent, brown-red, violet-brown; with sugar and sulphuric acid, dingy-brown; with sulphuric acid and bromine-water, transiently reddish; with fuming nitric acid, blood-red; with nitric acid sp. gr. 1.4, brownish resinous. The integuments of the seed appear to be the principal seat of the alkaloids, one of which yields a crystalline sparingly soluble salt with chromic acid (*Pharmacographia*).

The seeds contain from 25 to 30 per cent. of non-drying fixed oil, resins, coloring matter, and other constituents not investigated; they yield about 8 to 10 per cent. of ash.

Allied Plants.—*DELPHINIUM CONSOLIDA*, *Linne*.—Larkspur, Lark's claw, Knight's spur, *E.*: Pied d'alouette, *Fr.*; Rittersporn, Lerchenklau, Hornkimmel, *G.*—This glabrous annual herb, which is a common weed in the grain-fields of Central Europe, is often met with as an ornamental plant in gardens, and has been naturalized in some parts of the United States from Pennsylvania to Virginia. It has the leaves dissected into narrow linear lobes, and its purplish-blue (in cultivation sometimes whitish) flowers are upon rather filiform peduncles in loose terminal racemes. The five sepals are petal-like, the upper one produced into a spur longer than the calyx: the petals are united, with one spur enclosed in the calyx-spur: the pistil is single, and the smooth follicle many-seeded. The seeds are quite small, about $\frac{1}{16}$ inch (1.5 Mm.) in diameter, irregularly tetrahedral, pointed, rough, and pitted upon the surface, with a black testa and a whitish nucleus consisting of an oily albumen and a small straight embryo. All parts of the plant are inodorous and have a bitter, burning, and biting taste. The plant is said to have received its specific name from the supposed power of its flowers of healing or consolidating wounds. The *consoude* of the French is comfrey.

The leaves, flowers, and seeds have been employed in medicine, and were designated as *herba, flores, et semen consolide*, *s. consolide regalis*, *s. calcatrippe*: the seeds as *delphinium* (*C. S. P.* 1870). Thos. C. Hopkins (1839) obtained from the seeds an alkaloid which he regarded as identical with delphinine. Masing (1883) obtained from the dry herb 0.02 per cent. of *calcatripine*, which is soluble in alcohol, ether, and chloroform, and appears to be easily decomposed by chemicals. It is colored by sulphuric acid red-brown, violet-brown, gray-brown: by Fröhde's reagent, olive-green, gray-yellow; by sugar and sulphuric acid, red-brown, greenish-blue; by sulphuric acid and a nitrate, orange-red, golden-yellow.

DELPHINIUM AJACIS, *Linne*, of Southern Europe, is more frequently cultivated in gardens than the preceding species, has denser and longer racemes of flowers upon shorter and thick peduncles, and pubescent follicles, and possesses the same properties.

DELPHINIUM EXALTATUM, *Aiton*, is 4 or 5 feet (1.2–1.5 M.) high, and has the segments of the leaves narrow and cuneiform: the bright purplish-blue numerous flowers are in a narrow raceme and have a straight spur a little longer than the calyx. The plant grows in the Middle States.

DELPHINIUM AZERUM, *Michaux*, grows from Wisconsin to Arkansas and the Rocky Mountains, is 2 or 3 feet (60 or 90 Cm.) high, and has linear leaf-lobes and sky-blue or whitish flowers with a curved or ascending spur.

Medical Action and Uses.—The no longer officinal plant, or larkspur, of which the flowers, as well as the seeds, have been employed in medicine, and also the tall larkspur (*D. exaltatum*), appear to possess acid and irritant qualities, and in large doses to excite vomiting and purging. They have been used in the treatment of *dropsy* and *spasmodic asthma*, generally in the form of a tincture, which has also been much employed as a lotion or in an ointment for the cure of *itch* and the destruction of *lice*. It has of late been recommended for similar purposes (*Bull. de therap.*, civ. 480) and for ulcerated *buboes*. An infusion of the flowers in water or in vinegar, 3 parts in 100, has been used. Analogous qualities are ascribed to *D. Ajacis* by Benvenuti, who states that it hastens the cic-

trization of wounds, as *D. consolida* is also believed to do. These effects are due to the alkaloid *delphinine*, which has also been obtained from *D. staphisagria*. It has an acrid, hot taste, irritates the fauces, and is emetic and purgative. Given to dogs and cats in doses of $\frac{1}{4}$ to $\frac{2}{3}$ grain (Gm. 0.01–0.04), it causes depression, evidences of nausea, and a flow of saliva from the mouth, followed by violent vomiting, with signs of distress, and sometimes diarrhoea. Gradually the animal loses the power of voluntary movement, sensibility, and reflex excitability, but from time to time is affected with spasms, and in from 2 to 24 hours of a soporose condition perishes in a tetanic convulsion. Salivation continues during the entire attack, and respiration gradually grows slower and deeper until great dyspnoea occurs, with abrupt inspiration and labored and protracted expiration. In a word, death takes place by asphyxia. After death the heart is found in diastole. The gastro-intestinal mucous membrane is inflamed. In an ointment and rubbed upon the skin, delphinine causes a burning and prickling sensation and a transient redness, such as veratrine occasions. In the case of a man affected with torpor of the brain and abnormal excitability of the spinal cord Albers observed the following effects of doses of gr. $\frac{1}{3}$ (Gm. 0.015) repeated four times a day for several days: salivation, burning, redness, and swelling of the throat, nausea, retching, loss of appetite, straining at stool without evacuation, dysuria, prickling and itching of the skin, great restlessness, and a small but otherwise normal pulse. The intelligence was not further impaired, and the muscular power was rather augmented (Albers, *Prager Vierteljahrs.*, lxii.; *Analekt.*, p. 14). According to Boehm, staphisagrin (staphisaine) is a much less powerful poison to animals than delphinine, whose action, however, resembles its own in causing death by asphyxia. But it does not produce the energetic convulsions of delphinine, nor depress the pulse like that alkaloid; nor does it affect the cerebral functions, for the animals under its influence continue to react almost until death, and do not fall into a comatose condition.

Delphinine has been used with reputed success in the local treatment of *neuralgia* by applying it over the superficial sensitive points of the affected nerves. *Eurache* and *toothache* have also been relieved by it. The dose of delphinine is stated to be $\frac{1}{4}$ grain (Gm. 0.03) repeated at intervals of three or four hours. A solution of from 16 to 30 grains of the alkaloid in an ounce of alcohol (Gm. 1–2 in Gm. 32) may be used as a liniment, and an ointment may contain from 10 to 40 grains (Gm. 0.60–2.60) of delphinine to an ounce of lard.

STATICE.—MARSH ROSEMARY.

Inkroot, *Sea-lavender*, E.; *Romarin des marais*, *Lavande triste*, Fr.; *Strandmelke*, G.

The root of *Statice Limonium*, *Linné*, variety *caroliniana*, Gray (*Statice caroliniana*, Walter). Bentley and Trimen, *Med. Plants*, 166.

Nat. Ord.—Plumbaginaceæ.

Origin.—Marsh rosemary is a perennial acaulescent plant which grows near the seashore and in inland salt marshes of Southern and Western Europe. The variety *caroliniana* is an American plant, and grows in similar localities on the Atlantic coast. It has a tuft of spatulate-oblong or oblanceolate, bristly pointed, one-ribbed leaves, and produces in August a much-branched, panicleed scape, about 20 inches (25 Cm.) high, bearing numerous small lavender-colored or purplish-blue flowers; the fruit is a one-seeded utricle contained in the base of the calyx. The root should be collected in autumn.

Description.—The root of marsh rosemary is several-headed, from 1 to 2 feet (30–60 Cm.) long and an inch (25 Mm.) or more thick. The upper part is closely annulate, and the stout branches, after drying, are longitudinally wrinkled. The root has a deep brownish-purple color externally, is somewhat paler internally, fleshy in the fresh state, and after drying tough and compact. It breaks with a short fracture, exhibiting a rather thick bark, and in the medullium narrow pale-yellowish wood-wedges. The root is without odor and has a strongly astringent and slightly bitter taste. E. L. Reed (1879) stated that when collected from swampy localities the root is long and little branched, but when grown in a sandy soil it is short and considerably branched.

Constituents.—Edward Parrish (1842) found in the root 12.4 per cent. of tannin, a trace of volatile oil, a little caoutchouc-like matter, gum, and other common vegetable principles; among the inorganic constituents the sulphates and the chlorides of sodium and magnesium were found. H. K. Bowman (1869) estimated the tannin by means of gelatin, and determined the amount to be from 14 to 18 per cent. of the air-dry root. It reacts greenish-black with ferric salts.

Allied Drugs.—The roots of most other species of *Statice* have similar properties. *St. speciosa*, *Linné*, is used in Siberia; *St. latifolia*, *Smith*, in Southern Russia; and *St. brasiliensis* in Brazil, where it is known as *baycura* and *biacura*; the latter contains 12.5 per cent. of tannin and 1.3 per cent. of acrid pungent resin (Ch. Symes, 1878). F. A. Dalpe (1884) obtained from the air-dry root 9.7 per cent. of ash and an alkaloid, *baycurine*, which crystallizes from ether and chloroform in small white feathery needles and dissolves in sulphuric acid with a red color. *St. mucronata*, *Linné*, of Morocco, has a root with a whitish medullium, and is said to possess nervine properties.

Medical Action and Uses.—This plant was anciently renowned as a remedy for pulmonary and uterine hæmorrhage, and for *dysentery* and other fluxes. In recent times it has been used, like kino and other vegetable astringents, for similar purposes, and still oftener in gargles for the cure of ulcerated, aphthous, and other forms of *sore throat*. The emetic action ascribed to it is probably developed only when its dose is excessively large. It may be used in tincture, decoction, or infusion.

STILLINGIA, U. S.—STILLINGIA.

Queen's root, Queen's delight, Silver leaf, E.; *Stillingie*, Fr., G.

The root of *Stillingia sylvatica*, *Linné*, s. *Sapium sylvaticum*, *Torrey*. Bentley and Trimen, *Med. Plants*, 241.

Nat. Ord.—Euphorbiaceæ.

Origin.—A perennial laticiferous herb growing in dry and sandy soil in the Southern United States as far north as Eastern Virginia. The stems are erect, 2 or 3 feet (60–90 Cm.) high, and have nearly sessile, alternate, elliptic, or lance-oblong, finely serrate, smooth, and spreading leaves. The flowers are small, in dense catkin-like spikes, the upper ones with two stamens, the lower ones pistillate, fertile, and with three diverging stigmas on the thick style. The root should be collected late in autumn or early in spring.

Description.—*Stillingia*-root is about a foot (30 Cm.) long, nearly 2 inches (5 Cm.) in diameter above, tapering downward, little branched, but somewhat fibrous. It is crowned with the short remnants or scars of numerous stems, is fleshy when fresh, after drying compact and wrinkled longitudinally. Externally, it is of a light brown-gray color, and internally of a pinkish tint. The root is tough and tenacious and breaks with a fibrous fracture. On transverse section are seen a rather thick bark, the inner layer of which is pale pinkish-brown and dotted with numerous brown-yellow resin-cells, and a radially striate porous medullium containing resin-cells in the medullary rays. The odor of the fresh root is rather strong and disagreeable, but after drying is much weaker and less unpleasant; its taste is bitter and acrid, leaving a burning impression on the palate.

Constituents.—From some experiments made by Wm. Saunders (1868), it appears that, though the odor of the root may be diminished on drying and keeping, the pungency is scarcely lessened by exposure for a year to light and air. The pungency seems to be due to a resinous constituent which is readily soluble in alcohol. The so-called *oil of stillingia*, as found in the market, is intended to be the ethereal extract, but sometimes possesses scarcely any of the persistent acrimony of the root. *Stillingia* contains also starch, tannin, and, according to J. H. Harmanson (1882), another principle, which, like tannin, discharges the blue color of iodide of starch, and which is insoluble in alcohol and ether, but readily soluble in hot water, and is destroyed on being boiled with diluted acids.

Allied Species.—*STILLINGIA* (Excœcaria, *Müller*, *Croton*, *Linné*, *Sapium*, *Roxburgh*) SEBIFERA, *Michaux*. This is a medium-sized tree indigenous to China and somewhat cultivated in tropical countries. The ovate three-celled fruit contains three seeds imbedded in a solid inodorous fat, which consists principally of palmitin, with a little stearin, melts at 44.5° C. (112° F.), and is known as *Chinese tallow*. After separating the tallow by boiling water, the seeds yield by pressure a drying oil which melts at 35° C. (95° F.), and then remains liquid for a long time.

Off. Prep.—*Extractum stillingie fluidum*, U. S.

Medical Action and Uses.—The root, when chewed and the juice swallowed, causes heat in the mouth and fauces and along the œsophagus, increased salivation, and burning in the stomach, and in susceptible persons vomiting also. It loses these qualities by drying (Frost). *Stillingia* was originally introduced as an emetic and alterative, and has been more or less used, especially in the Southern States, for the cure of *scrofula*, *syphilis*, and *cutaneous* and *hepatic* disorders. The evidences of its power do not appear to be very convincing. Thus, it is credited with curing phagedenic chancres which

nothing else could arrest, but it appears that with each dose of a decoction of stillingia 4 drops of nitric acid were given. Now, nitric acid is reputed to cure syphilis. In 1846, Frost claimed for it curative virtues in scrofula and syphilis, but he associated with it sarsaparilla, guaiac, and sassafras (*Charleston Jour.*, i. 617). A similar estimate must be formed of the judgment expressed by Lopez (*New Orleans Med. and Surg. Jour.*, ii. 40), and by Cornell (*Boston Med. and Surg. Jour.*, Aug. 1857, p. 37). Stillingia is best given in a decoction made with an ounce of the bruised root in 1½ pints (Gm. 32 in Gm. 750) of water, gradually reduced to a pint. *Dose*, a wine-glassful two or three times a day. The *dose* of the powder is from 15 to 30 grains (Gm. 1-2).

STRAMONII FOLIA, U. S., P. G.—STRAMONIUM-LEAVES.

Herba stramonii.—*Thornapple-leaves*, E.; *Feuilles de stramoine*, Fr.; *Stechapfelblätter*, G.

STRAMONII SEMEN, U. S.—STRAMONIUM-SEED.

Stramonii semina, Br.; *Stramonium-seeds*, E.; *Semences (graines) de stramoine*, Fr.; *Stechapfelsamen*, G.

The leaves and seeds of *Datura Stramonium*, *Linné*. Woodville, t. 74; Bentley and Trimen, *Med. Plants*, 192.

Nat. Ord.—Solanaceæ.

Origin.—Stramonium is known in the United States as *Jamestown weed* and *Jimson weed*. It is very unequally distributed, being quite common in some localities and rare

FIG. 287.

Datura Stramonium, *Linné*: flowering branch.

in others, and grows in waste places and along roadsides throughout the greater part of the world, with the exception of the colder countries. Its native country is not certainly known, but it is now by most botanists believed to be indigenous to Asia. De Candolle refers it to the countries bordering on the Caspian Sea; others regard it as coming from Northern India. It is a coarse-looking annual weed, with a white, conical, branching root and an erect, nearly smooth, pale-green, and succulent stem,

FIG. 288.

Capsule, mature, and with two valves removed, showing partitions and position of seeds (reduced).

FIG. 289.

Stramonium-seed and section, magnified 3 diam.

attaining, with its repeatedly forking branches, a height varying from 2 to 5 feet (0.6-1.5 M.). The flowers are on short stalks singly in the forks, have a long tubular five-angled calyx with a short five-toothed limb, and a white, tubular, funnel-shaped, five-plaited, and five-pointed corolla about 4 inches (10 Cm.) long. The capsule is 2 to 3 inches (5-7 Cm.) long, surrounded below by the spreading base of the calyx, ovate in shape, obtusely quadrangular, covered with spines, in the lower portion four-celled, but only two-celled above, opens by four valves, and contains numerous seeds.

Datura Tatula, *Linné*, resembles the officinal plant very closely, is found in similar localities, and is distinguished by its purple-colored stem, the darker-green foliage with occasionally purplish petioles and nerves, and by the purple color of the flowers and anthers. Many botanists regard it merely as a variety of *Stramonium*, but there are evident hybrids between the two forms, and, according to Naudin (1852), the seedlings from

these are again either *D. Stramonium* or *D. Tatula*. De Candolle considers this species to be indigenous to South America, but it has spread over the greater part of the world.

Description.—1. **THE LEAVES.** These should be collected while the plant is in bloom, which commences early in summer. They are situated on the forks on long petioles, vary in length from 3 to 8 inches (7–20 Cm.) and in width from 2 to 5 inches (5–12 Cm.), are ovate in shape, and have an unequal base, one side being decurrent on the petiole. The apex is pointed and the margin coarsely and unequally sinuate-toothed. The leaves are rather fleshy when fresh, and have a disagreeable narcotic odor, but after drying are thin, brittle, and nearly inodorous. Young leaves are downy; older ones are smooth or slightly downy on the nerves beneath, and frequently perforated with nearly circular holes. Their taste is unpleasant, saline, and bitter.

2. **THE SEEDS.** When ripe the seeds are of a dull brownish-black color, about $\frac{1}{10}$ inch (4 Mm.) long, $\frac{1}{10}$ inch (2.5 Mm.) broad, and about $\frac{1}{25}$ inch (1 Mm.) thick; they are reniform, flattened, finely pitted, and somewhat coarsely reticulate, and have the hilum on the sinus. The testa is hard, and encloses a white oily albumen in which is imbedded the cylindrical embryo, curving parallel with the edges of the seed. The seeds are inodorous or nearly so, except after being bruised, when they emit a heavy unpleasant odor; their taste is oily and bitter.

Constituents.—The alkaloid *daturine* was discovered in the seeds by Geiger and Hesse (1833), and subsequently found in other parts of the plant. According to Brandes, the seeds contain it combined with malic acid. Von Planta (1850) pronounced this alkaloid to be identical with atropine in composition, solubility, and fusibility. But the physical experiments performed by Von Schroff (1852) demonstrated the two alkaloids, though acting qualitatively alike, to be very unequal in their effects, daturine being about twice as strong as atropine. Subsequently, Erhard (1866) observed also some of their salts to differ in their crystalline forms. These differences have been explained through the researches of Ladenburg (1880), according to which daturine is a mixture of *atropine* and *hyoscyamine* (see pp. 283 and 802), the latter usually predominating; but Ernst Schmidt (1881) obtained also daturine which consisted principally of atropine. The other constituents of the seeds are about 25 per cent. of a bland fixed oil, mucilaginous, resinous, and other common principles, and about 3 per cent. of ash. Trommsdorff isolated *stramonin* as a white tasteless powder, insoluble in water, readily soluble in fixed and volatile oils, soluble in ether, and sparingly soluble in alcohol; it does not appear to have been further investigated. The leaves contain only about .02 per cent. of alkaloid, besides mucilage, albumen, nitrate of potassium, etc.; they yield about 17 per cent. of ash.

Allied Drugs.—*Datura alba*, Nees, of India, has rather small subglobular and sharply spinous capsules and irregular triangular yellowish-brown, roughish seeds, which are used like those of the preceding species.

Datura metel, Linné, which grows in Africa and Southern Asia, has obliquely cordate, somewhat sinuate-toothed or nearly entire, soft-hairy leaves, and pendulous spiny capsules with brownish-yellow seeds.

Datura sanguinea, Ruiz et Pavon, a shrub or small tree of Peru, has oblong, pointed, and sinuate-toothed, on the lower side downy, leaves, and large flowers with a corolla, the lower half of which is yellow and the upper half blood-red.

Off. Prep.—*Of the seed*: Extract. stramonii fluidum, U. S.; Extract. stramonii, Tinet. stramonii, U. S., Br.

History.—It is almost certain that stramonium was unknown to the ancients; it was described by Gerard in the sixteenth century, but it was first introduced into medical practice by Stoerck in 1762. The dried leaves and seeds are said to have been brought from Asia into Europe in the Middle Ages by the gypsies, who employed their smoke to intoxicate and delude their dupes.

Physiological Action.—*On Animals*: Insects of the caterpillar tribe feed upon stramonium and goats devour it without injury. A decoction of the leaves applied to the skin of a young rat caused alternate debility and convulsive movements. Very large doses given to the horse have induced gaping, drowsiness, and even death.

On Man: Stramonium and belladonna and their respective alkaloids, daturine and atropine, are almost identical in their action upon man. Indeed, they are held to be quite identical by some of the highest authorities (*Archives gén.*, Jan. 1881, p. 12). The powdered leaves of stramonium in 2-grain (Gm. 0.12) doses slightly increase the fulness and frequency of the pulse, occasion a little giddiness, and render the skin warm and the hands and face moist. 5-grain (Gm. 0.30) doses cause dilatation of the pupils,

difficulty of speech, nausea, thirst, dryness of the throat, relaxation of the bowels, an increased flow of urine, and some feverishness. Poisonous doses produce a condition like that of high fever with delirium; the patient may talk volubly and laugh, or become violent, biting and striking furiously, and usually there is evidence of various, and sometimes grotesque, hallucinations; the movements may resemble those in chorea or in alcoholic intoxication; the head is dizzy, heavy, or light, and there is a tendency to faint; the face is flushed, and occasionally swollen, the eye bright, the conjunctiva injected, the pupil dilated, and the sight confused; the skin is sometimes covered with a bright-red eruption, which may be followed by a crop of minute vesicles, or the eruption may resemble erysipelas at first and measles afterward. In some cases hydrophobic phenomena occur, the sight of water or the attempt to drink producing a convulsive paroxysm. In rare fatal cases the phenomena of excitement sooner or later are succeeded by stupor, insensibility, relaxation, and even paralysis; the pupils are inordinately dilated, the pulse is rapid and thready, and the skin hot and perspiring. In no case is there any tendency to sleep, but, on the contrary, persistent insomnia. When recovery takes place there is no distinct recollection of what has occurred. Among the perversions of the senses it has been noticed that all black objects appear green. A fatal case in a healthy man of fifty is reported by Newton (*Med. Record*, xviii. 289), and recent cases of recovery have been published by Terry (*Boston Med. and Surg. Jour.*, Feb. 1882, p. 123), Rubio, etc. (*Phila. Med. Times*, xii. 458; xiii. 280). A curious illustration of stramonium intoxication is presented by the narrative of its use in Mecca for criminal purposes (*Jour. Am. Med. Assoc.*, i. 22). Daturine occasions phenomena essentially identical with the above and with those caused by atropine, but with more depression, failure of the pulse, and insensibility; according to some observers, it dilates the pupils more rapidly, although less persistently, than atropine. Other reporters, however, furnish a different result, asserting that as a mydriatic daturine is three times as strong as atropine and its action more prolonged. It is generally accepted, as being proved by the above phenomena, that stramonium and daturine expend their power mainly upon the vaso-motor nerves, in small doses contracting, but in large doses paralyzing, the capillaries. These actions are identical with those which experiment and observation have shown to be exerted by hyoscyamine. Regnault and Valmont concluded from their experiments that daturine is identical with atropine, and that hyoscyamine is often really impure atropine (*Archives gén.*, Jan. 1881, p. 16), and Oliver reached the same conclusion in regard to the action of daturine and hyoscyamine (*Amer. Jour. of Med. Sci.*, July, 1882, p. 102).

Medical Uses.—At one time stramonium was believed to be a valuable remedy in various forms of *insanity*, in *mania* as well as in *melancholia*, but experience has not confirmed the favorable judgment. Yet there are isolated cases in which phantasmal delirium appears to have been removed by this medicine. A similar statement may be made respecting its use in *epilepsy*, and there is at least every reason to regard it as not less efficacious than belladonna in that disease. The utility of stramonium in *spasmodic asthma* cannot rationally be called in question; the evidence in its favor is drawn from too many and too widely different sources to be gainsaid. The scepticism upon this point expressed by certain writers may fairly be attributed to their having failed to discriminate between pure asthma and asthma or dyspnoea connected with pulmonary or cardiac disease. In the latter category the medicine must usually fail, either partially or wholly, and may even aggravate the symptoms, while in pure nervous asthma there can be no doubt of its power to relieve the paroxysms. It should be used as follows: About 15 grains (Gm. 1) of dried stramonium-leaves or half that quantity of the fibres of the dried root may be smoked at once, mixed with sage-leaves or tobacco in a pipe or a cigarette. Or else tobacco steeped in a strong decoction of stramonium may be smoked in a pipe, or cigars impregnated with the same liquid may be used. If possible, the smoke should be drawn into the lungs. An atomized decoction of stramonium has been used, but is less efficient. Of other spasmodic affections more or less benefited by this medicine may be mentioned *whooping cough*, *dysmenorrhœa*, and *retention of urine* caused by spasm of the neck of the bladder. In the latter case bruised fresh stramonium-leaves may be used or stramonium ointment may be rubbed upon the perineum. The rectal tenesmus, burning pain, etc. due to *hemorrhoids*, *fissure*, and other affections of the anus and rectum may be greatly palliated by stramonium. A convenient formula for this purpose is the following: $\mathcal{R}$. Ung. stramon., Ung. gallæ, Cerat. plumbi subacet., āā q. s. —**M. S.**—Apply within the anus after defecation and washing.

The apparent identity of the physiological actions of stramonium and belladonna and of their respective alkaloids naturally suggested an identity in their therapeutic powers.

But it does not really exist. Their differences are most conspicuous in the treatment of *neuralgic* affections. In these belladonna is much more efficient than stramonium; indeed, while the former and atropine are among the most reliable of anti-neuralgic medicines, stramonium is comparatively inefficacious and daturine has been but little used. Moreover, stramonium is much more employed as a local anodyne in superficial neuralgia, while belladonna is even more active as an internal than as a topical remedy for these as well as the deeper-seated neuralgic affections. If stramonium is prescribed for them internally, it should be given in such repeated doses as will develop the specific action of the medicine.

In subacute and chronic articular and in muscular *rheumatism* bruised fresh stramonium-leaves produce an anodyne effect, and the ointment may be applied with some benefit, but the action of either is inferior to that of belladonna or of opium. There is some authority for attributing to stramonium in full and repeated doses a certain control over the course of acute articular rheumatism, but the evidence is too scanty and ambiguous to inspire much confidence.

In the absence of belladonna, stramonium may be used to produce *dilatation of the pupil*. It has this effect whether it is given internally or is topically applied. Daturine has been employed for the same purpose, and, as before stated, by some is held to be less irritating to the eye than atropine, while others make the opposite statement.

The average *dose* of the leaves or the root of stramonium is about 2 grains (Gm. 0.12), and of the seeds about 1 grain (Gm. 0.06), repeated at intervals of several hours and until it begins to dilate the pupil. The *dose* of daturine, hypodermically, is from $\frac{1}{10}$ to $\frac{1}{20}$ grain (Gm. 0.001–0.003).

The physiological and clinical antidote to stramonium is opium. Numerous cases are reported in which opium or its liquid preparations, and especially morphine hypodermically, have apparently saved the lives of persons poisoned by stramonium. In the case of an adult 15 grains (Gm. 1) of muriate of morphine were administered by the mouth before the safety of the patient was secured (Anderson, *Ranking's Abst.*, xxx. 276).

STRYCHNINA, U. S., Br., F. Cod.—STRYCHNINE.

Strychnia, Br., U. S. 1870; *Strychninum*.—*Strychnine*, Fr.; *Strychnin*, G.
Formula $C_{21}H_{22}N_2O_2$. Molecular weight 334.

Preparation.—Take of Nux Vomica 1 pound; Acetate of Lead 180 grains; Solution of Ammonia a sufficiency; Rectified Spirit a sufficiency; Distilled Water a sufficiency. Subject the nux vomica for 2 hours to steam in any convenient vessel; chop or slice it; dry it in a water-bath or hot-air chamber, and immediately grind it in a coffee-mill. Digest the powder at a gentle heat for 12 hours with 2 pints of the spirit and 1 of the water; strain through linen, express strongly, and repeat the process twice. Distil off the spirit from the mixed fluid, evaporate the watery residue to about 16 ounces, and filter when cold. Add now the acetate of lead, previously dissolved in distilled water, so long as it occasions any precipitate; filter; wash the precipitate with 10 ounces of cold water, adding the washings to the filtrate; evaporate the clear fluid to 8 ounces, and when it has cooled add the ammonia in slight excess, stirring thoroughly. Let the mixture stand at the ordinary temperature for 12 hours; collect the precipitate on a filter, wash it once with a few ounces of cold distilled water, dry it in a water-bath or hot-air chamber, and boil it with successive portions of rectified spirit till the fluid scarcely tastes bitter. Distil off most of the spirit, evaporate the residue to the bulk of about $\frac{1}{2}$ ounce, and set aside to cool. Cautiously pour off the yellowish mother-liquor (which contains the brucia of the seeds) from the white crust of strychnia which adheres to the vessel. Throw the crust on a paper filter, wash it with a mixture of 2 parts of rectified spirit and 1 of water till the washings cease to become red on the addition of nitric acid; finally, dissolve it by boiling it with an ounce of rectified spirit, and set it aside to crystallize. More crystals may be obtained by evaporating the mother-liquor.—*Br.*

This process is a modification of the one proposed by Wittstein. The tincture, prepared with about 55 per cent. alcohol, is concentrated, and the resinous and other insoluble matter separated by filtration. Acetate of lead precipitates from the filtrate igasuric acid and coloring matter, and leaves the alkaloids in solution as acetates. These are decomposed by ammonia, and the precipitated alkaloids treated with hot alcohol, from the concentrated solution of which strychnine crystallizes, and is entirely purified from brucine and coloring matter by washing with alcohol of about 55 per cent. and by recrystallization from strong alcohol.

O. Henry (1830) recommended the exhaustion of *nux vomica* by means of alcohol acidulated with sulphuric acid and the liberation of the alkaloids by lime. Duflos recommended a similar process, using acidulated water for exhausting the drug; and this is frequently followed when working on the large scale, and was adopted by the U. S. P. 1870. Powdered *nux vomica*, or the drug softened by steam and while hot crushed between rollers, is exhausted by boiling with very dilute hydrochloric or sulphuric acid; the decoction contains the alkaloids as hydrochlorates or sulphates, together with the liberated igasuric acid, mucilaginous compounds, coloring matter, and other principles. On the addition of slaked lime the salts of the alkaloids are decomposed, chloride or sulphate of calcium is formed, and strychnine and brucine are precipitated, together with the excess of lime employed, and with calcium sulphate. On washing this precipitate with water, the foreign principles are mostly removed, and by treatment with cold diluted alcohol the brucine is dissolved. The residue now consists essentially of lime and strychnine, the latter of which is taken up by boiling alcohol, and further purified by converting it into sulphate soluble in water, decolorizing with animal charcoal, and precipitating with an alkali; or, the washed and dried precipitate by lime is at once exhausted with boiling alcohol, and the mixed strychnine and brucine are purified by treatment with sulphuric acid, animal charcoal, and ammonia, and separated by dissolving in hot alcohol, when, on cooling, strychnine will crystallize and brucine remain in the mother-liquor.

Various other processes have been proposed, differing mainly in the manner in which the alkaloids are liberated and afterward separated from each other. Magnesia or carbonate of sodium may be substituted for the lime and ammonia in the above processes; and benzol was suggested by Boiraux and Léger (1875) for dissolving strychnine from the mixed alkaloids, brucine, it is stated, being completely insoluble in that menstruum.

Properties.—Strychnine is seen in commerce as a white crystalline powder or crystallized in colorless, short, quadrangular prisms or octahedrons of the rhombic system. It is permanent in the air, inodorous, has a very persistent bitter taste, which is still perceptible if strychnine is dissolved in 600,000 or 700,000 parts of liquid. The alkaloid has an alkaline reaction, melts below 300° C. (572° F.), is sublimable only when very minute quantities are carefully heated (Hellwig, 1864), and is decomposed at a higher heat. Pelletier and Caventou, who discovered this alkaloid in 1818, found it soluble in about 6700 parts of cold and 2500 parts of boiling water, and to be insoluble in absolute ether. It requires 120 parts of cold and 10 parts of boiling 80 per cent. alcohol for solution (Wittstein); but it is very sparingly soluble in absolute and in dilute alcohol; it dissolves in 110 parts of alcohol (U. S.); in 107 parts of 95 per cent. alcohol, 180 parts of amyl alcohol, 165 parts of benzol, and in 1250 parts of commercial ether (Dragendorff); in about 5 parts of chloroform (Pettenkofer); in 300 parts of glycerin (Cass and Garot); and is also soluble to some extent in volatile and fixed oils and in creasote. Its solubility in water is not increased by ammonia or caustic potassa, but dilute acids render it much more soluble, with the formation of neutral salts, which are mostly crystallizable and are precipitated by alkalies, alkali carbonates, chromates, and, after some time, by soluble bicarbonates. Lextrait (1881) obtained long needles of a compound consisting of 3 molecules of strychnine and 1 of iodoform; it becomes yellow at 90° C. (194° F.), is very sparingly soluble in alcohol, and dissolves freely in ether and chloroform, decomposing when kept in solution.

Strychnine and its salts dissolve in concentrated sulphuric acid without color, but on the addition of a little peroxide of lead a beautiful blue color is produced, passing into violet, red, and finally into yellow (Marchand). If a small crystal of potassium bichromate is used instead of the lead oxide, a deep-violet color is produced, or a blue color if strychnine is in excess (Otto). A similar color is obtained with sulphuric acid and ferri-cyanide of potassium (Davy); it passes like the preceding, though more slowly, through red into yellow, and finally fades. The solution of strychnine in sulphuric acid containing some nitric acid yields on the addition of binoxide of manganese a purplish-violet color (Mack, Erdmann), and a similar color, but rapidly fading to yellow, is produced with chloric, chlorous, and iodic acids and their salts, with manganic sulphate and potassium permanganate (Lefort). If much contaminated with organic matter, the alkaloid is best purified by dissolving it in a dilute acid, so as to free it from fatty and resinous matters, liberating it by ammonia, and dissolving it by agitation with chloroform; if necessary, the process is repeated, and the residue from the evaporation of chloroform is tested as above. If the above tests are carefully applied, a very minute quantity may be detected, according to Wenzell (1870), in a solution containing the $\frac{1}{999999}$ part of strychnine.

The composition of strychnine is expressed by the formula $C_{21}H_{22}N_2O_2$ (Regnault); according to Schützenberger (1858), it sometimes contains 22 or 20 C.; Claus (1881) observed a strychnine with 22C.

Tests.—The freedom from inorganic matters is readily proven by the absence of ash on incinerating a portion. Concentrated nitric acid should not produce a red color, or only a very faint one, showing the absence of more than traces of brucine.

Off. Prep.—Liquor strychninæ, Br.; Ferri et strychn. citras, Syrup. ferri quin. et strychn. phosphatum, U. S.

STRYCHNINÆ SULPHAS, U. S.—SULPHATE OF STRYCHNINE.

Strychninum sulfuricum.—Sulfate de strychnine, Fr.; Schwefelsaures Strychnin, G.
Formula $(C_{21}H_{22}N_2O_2)_2H_2SO_4 \cdot 6H_2O$. Molecular weight 874.

Preparation.—In preparing this salt it is best to use the strychnine in the form of powder, and add it in slight excess to warm dilute sulphuric acid; the filtrate from the undissolved strychnine will yield the salt on being evaporated spontaneously to dryness; on the cooling of the hot saturated solution a salt with $5H_2O$ crystallizes in long thin prisms.

Properties.—Sulphate of strychnine crystallizes in transparent and colorless quadratic octahedrons containing 12.36 per cent. water of crystallization, the whole of which is given off below $200^\circ C.$ (Rammelsberg, 1881); according to Regnault (1838), the loss at $135^\circ C.$ ($275^\circ F.$) is 13.08 per cent. The salt has a neutral reaction, is inodorous, and has the intensely bitter taste and the color reactions of strychnine salts. On exposure it becomes superficially opaque. It is stated to be soluble in 48 parts (Abl) and in less than 10 parts (Pelletier and Caventou) of water; according to the U. S. P., it is soluble in 10 parts of water and in 60 parts of alcohol at $15^\circ C.$ ($59^\circ F.$), in 2 parts of boiling water, and in 2 parts of boiling alcohol; also soluble in 26 parts of glycerin, but insoluble in ether. M. W. Coleman (1883) determined it to be soluble at $15^\circ C.$ in 42.76 parts of water, to contain $6H_2O$, to become anhydrous at $185^\circ C.$ ($365^\circ F.$), without previously melting, and to be decomposed at about $225^\circ C.$ ($437^\circ F.$). Lextrait (1882) recommends the salt with $5H_2O$, which is uniformly obtained by crystallizing from alcohol of more than 50 per cent. strength. The aqueous solution of the salt gives with barium chloride a white precipitate of barium sulphate, and with potassa or ammonia a white precipitate of strychnine which shows the reactions described above. When heated to redness the salt should leave no residue.

From the observations of Rammelsberg and of Lextrait it appears that in Europe the normal and acid sulphates are used indiscriminately; the former (pharmacopœial) salt contains 75.43 per cent. of strychnine, while the latter contains 71.36 per cent., its formula being $C_{21}H_{22}N_2O_2 \cdot H_2SO_4 \cdot 2H_2O$, and it becomes anhydrous at $150^\circ C.$ ($302^\circ F.$).

Other Salts of Strychnine.—STRYCHNINÆ ACETAS. The neutral salt crystallizes with difficulty, and on evaporating its solution loses a portion of the acid; it dissolves in 96 parts of water and in 15.1 parts of chloroform.

STRYCHNINÆ HYDRIODAS, $C_{21}H_{22}N_2O_2 \cdot HI$; molecular weight 461.6. It is sparingly soluble in cold water, but dissolves more freely in alcohol. It is prepared by adding solution of potassium iodide to the solution of a strychnine salt, dissolving the precipitate in alcohol, and crystallizing. It forms quadrangular needles or white scales, has a very bitter taste, and contains 72.3 per cent. of strychnine.

STRYCHNINÆ HYDROBROMAS, $C_{21}H_{22}N_2O_2 \cdot HBr$; molecular weight 414.8. Bullock (1875) recommended its preparation from 45 grains of sulphate of strychnine dissolved in a mixture of 1 fluidounce of water and 2 fluidrachms of alcohol. To this solution is added a solution of 11.7 grains of potassium bromide in 1 fluidrachm of water and 1 fluidounce of alcohol. The precipitated potassium sulphate is filtered off, the filtrate is mixed with a fluidounce of water, concentrated, and crystallized. It forms prismatic needles which are sparingly soluble in alcohol, more readily soluble in dilute alcohol, and require about 32 parts of cold water for solution. It contains 80 per cent. of strychnine.

STRYCHNINÆ HYDROCHLORAS, $(C_{21}H_{22}N_2O_2 \cdot HCl) \cdot 3H_2O$; molecular weight 794.8. It is best prepared by dissolving strychnine in warm dilute hydrochloric acid, and crystallizes in silky needles, which lose their water of crystallization at $120^\circ C.$ It dissolves in 50 parts of cold water, and contains 84 per cent. of strychnine.

STRYCHNINÆ NITRAS: Strychninum nitricum, P. G. On dissolving strychnine in warm very dilute nitric acid the solution yields, on cooling, colorless needles of a silky lustre and very bitter taste. The salt is soluble in 90 parts of cold and in 3 parts of boiling water, and in 70 parts of cold and 5 parts of boiling alcohol. It is less freely soluble in absolute alcohol and fixed oils, is insoluble in ether, but dissolves in 26 parts of glycerin. Its composition is $C_{21}H_{22}N_2O_2 \cdot HNO_3$; molecular weight 397. It contains 84 per cent of strychnine.

History.—It is singular that the history of any powerful and peculiar medicine should be so obscure as that of *nux vomica*, the original source of strychnine. The very name that it bears, *nux vomica*, is a misnomer, since vomiting is not a symptom which is often produced by it in any dose. It is, however, more apt to be caused by *nux vomica* than by strychnine. It was known to the Hindoos as a poison, and seems to have been introduced into Europe in the sixteenth century. It is very curious that during the sixteenth, seventeenth, and a part of the eighteenth centuries, although it was well known to be poisonous to animals, it was affirmed not to be so to man. So delusive is negative testimony!

Physiological Action.—*On Plants:* Very minute portions of strychnine in the soil will destroy the life of growing plants. The same effect follows its inoculation into their branches.

On Animals: It acts poisonously upon all animals, but in different degrees. Flies die in convulsions, and intestinal worms are destroyed by it. Fishes placed in water containing the $\frac{2.5}{1000}$ part of muriate of strychnine or of brucine die within 10 minutes, and in a solution containing about 1 part of strychnine to 150,000 parts of water a minnow died within 20 minutes in a state of lateral rigidity (Gray). It is alleged, on the other hand (Falk), that serpents and fish exhibit no tetanic phenomena, but disturbance of the breathing, trembling, and jerking of the muscles, exhaustion, insensibility, and death. The frog is generally considered to be so exceptionally sensitive to the action of strychnine as to be employed as a test of the presence of this alkaloid in solution; for if $\frac{1}{1000}$ of a grain be dissolved in a drop of water and applied to the skin of the animal's back, previously dried, tetanoid spasms occur in from a quarter of an hour to one hour. The same effect is produced by the subcutaneous injection of the $\frac{2}{1000}$ of a grain of the acetate of strychnine under the skin of a healthy frog, or by that of $\frac{1}{2000}$ of a grain in the case of a frog exhausted by drying its skin, so as to impede the natural elimination of the poison through the integument. It is claimed by some experimenters that, in proportion to its weight, the frog is really less susceptible to strychnine than various mammals, and that it requires four times the dose needed by dogs, cats, rabbits, etc. to produce an equal effect on frogs (Falk). Birds appear to be comparatively insusceptible to the poisonous action of this substance. Thus in one experiment *nux vomica* was given to a hen in progressively increasing doses, until it took $2\frac{1}{2}$ drachms of the poison every day. Ruminating animals are less easily affected than other quadrupeds, at least when the poison is given by the mouth; for while 10 grains thus administered may fail to kill a sheep, $\frac{1}{4}$ or $\frac{1}{2}$ grain of strychnine will be fatal if introduced hypodermically or injected into the pleural cavity or into the veins. A similar result of experiment on the goat has been observed. Dogs very readily manifest the power of this substance, but cats resist it singularly, whether it be administered by the mouth or veins or subcutaneously. Vulpian states that the hypodermic injection of 1 Mgm. (gr. $\frac{1}{64}$) of muriate of strychnine dissolved in water, is sufficient to kill a full-grown rabbit, and that from two and a half to three times this quantity will be fatal to a medium-sized dog. When strychnine has been employed in fulminating balls to kill whales, it has been observed that these mammals perish in spasms. Guinea-pigs and monkeys are said to be comparatively insusceptible to it. The phenomena in the various cases in which its specific operation is developed consist of tremors, twitchings, and startings of the voluntary muscles, followed by tetanoid spasms, during which the heart's action is accelerated, the temperature raised, and the respiration and consciousness suspended. Between the spasms the circulation generally becomes normal, the consciousness returns, and cutaneous hyperæsthesia is observed, but the spasms may be renewed by any excitation, as a touch, a loud sound, or a sudden impression on the eye. Death may occur through asphyxia from tonic spasm of the respiratory muscles, by syncope, or by exhaustion. The heart continues to pulsate after the respiratory movements have ceased. Of these modes of death, that during spasm is by far the most frequent in cases of strychnine-poisoning. No lesion is uniformly found after death; the heart may be distended with black blood or empty, and, although congestion and serous effusion within the meninges of the brain and spinal cord are usual, they are not uniformly met with, and in the substance of these organs no characteristic alterations have been observed.

The experiments of Dr. W. H. Klapp (1878) led him to conclusions which may thus be summarily expressed: 1. Strychnine produces no primary lesion of the nerve-substance proper. 2. Its convulsions are not cerebral. 3. It does not affect either the sensory or motor nerves at their periphery. 4. These nerves are unaffected by it in their course. 5. Its tetanizing effects depend upon its action on the gray matter of the spinal cord.

6. In small doses it excites the vaso-motor centre. 7. In large doses it paralyzes that centre. 8. It slows the pulse by an immediate action upon the excito-motor ganglia of the heart. 9. It does not act on the pneumogastries, but decreases the number of respiratory movements, at first from too little blood, and afterward from too much blood flowing to the respiratory centres. 10. Artificial respiration always moderates the spasms, not by a reflex stimulation of the pneumogastries, but by maintaining the oxygenation of the blood until the poison is eliminated.

It may, then, reasonably be believed—1, that strychnine does not act upon the muscles, the nervous extremities, or the nerve-trunks; 2, that it does act upon the nerve-centres in the medulla oblongata and medulla spinalis; and, 3, that it acts upon those centres first by stimulating them when given in small doses, and by exhausting them, and thereby exaggerating their reflex irritability, when poisonous doses are used, in this respect falling under the general law that the actions of small and of large doses of an active agent are antagonistic to one another. (Compare Poole, *Med. Record*, xix. 201.) The latter of the two effects are probably dependent, in part at least, upon the power of strychnine to contract the arteries and the heart and to slow the pulse. It is essentially through spasm, in so far as it throws the respiratory muscles into tonic contraction and by rendering the chest immovable, that it tends to produce asphyxia, with its usual symptoms of dark venous congestion of the eyes and interior of the mouth. This explanation renders clear the agency of artificial respiration in saving the life of animals in strychnine-poisoning (Richet, *Med. News, etc.*, Nov. 1880, p. 659), and the effect of keeping the frog's skin moist in preventing or delaying the fatal action of the poison upon this animal. In both cases the blood continues to be oxygenated until the poisonous excess of strychnine has been eliminated.

The antagonisms presented by strychnine relate chiefly to chloral hydrate, aconite, hydrocyanic acid, and nicotin, or the special heart-poisons. In regard to the first, it has been shown by J. Hughes Bennett—1, that after a lethal dose of strychnine life may be saved by bringing the animal under the influence of chloral hydrate; 2, that chloral hydrate is more likely to save life after a fatal dose of strychnine than strychnine is to save life after a fatal dose of chloral hydrate; 3, that after a dose of strychnine producing severe tetanic convulsions these convulsions may be much reduced, both in force and frequency, by the use of chloral hydrate; 4, that the extent of physiological antagonism between the two substances is so far limited that (*a*) a very large fatal dose of strychnine may kill before the chloral hydrate has had time to act, or (*b*) so large must the dose of chloral hydrate be to antagonize an excessive dose of strychnine that there is danger of death from the effects of the former; 5, chloral hydrate mitigates the effects of a fatal dose of strychnine by depressing the excess of reflex activity excited by that substance, while strychnine may mitigate the effects of a fatal dose of chloral hydrate by rousing the activity of the spinal cord, but it does not appear capable of removing the coma produced by the action of chloral hydrate on the brain. The experiments of Dr. J. Milner Fothergill appear to show that the antagonism of strychnine and aconitine is very marked, so far as the influence of the former upon lethal doses of the latter is concerned; those of Brunton and others give equivocal evidence of the antidotal power of hydrocyanic acid in poisoning with strychnine. The experiments of Dr. Francis L. Haynes led him to these conclusions: 1, strychnine and nicotin are in no degree antagonistic poisons; 2, strychnine increases the convulsive action, and does not diminish the motor paralysis, of nicotin; 3, nicotin (even in paralyzing doses) increases the convulsive action of strychnine; 4, both poisons cause death by paralyzing the respiratory apparatus: they may affect respiration in different ways, but the result is the same; 5, animals may be killed by injecting together doses of the two drugs which, singly, are not fatal.

On Man: Powdered nux vomica and also strychnine rubbed upon the skin persistently act as local irritants; this action is greatly intensified if they are applied to the raw cutis, and may be attended with specific general symptoms. In small doses, internally, they are tonics, increasing the appetite and the urinary secretion, and the fecal discharges also when these are infrequent, but diminishing the latter when their frequency is due to atony of the bowels. Like other bitter tonics, their prolonged and excessive use deranges the digestion. They appear to augment the biliary and pancreatic secretions. Strychnine is excreted with the urine, and occasions an increased frequency of urination, but in excess produces spasm of the neck of the bladder, and ultimately impaired contractile power in this organ. It probably excites uterine contraction, promotes menstruation, disposes to venery, and provokes erections of the penis. It exerts no perceptible action upon the brain, but seems to increase the func-

tional activity of the special senses. In medicinal doses it usually produces no definite and direct effects upon healthy persons, or only a slight formication of the skin and a transient rigidity of the lower jaw and limbs, but in recently paralyzed parts the same doses may excite spasm. Like many medicines which act upon the nervous system, strychnine readily induces tolerance, so that enormous doses of it may be taken without evidences of poisoning. But, on the other hand, extremely minute doses sometimes develop the toxic effects of the preparation.

As experiments upon animals demonstrate, strychnine is absorbed by the veins and the lymphatics and when introduced into the connective tissue or the serous cavities; it is said to be more readily absorbed from the rectum than from the stomach, and but little from the urinary bladder. By the stomach it is, like other soluble substances, much more readily absorbed when in solution than in the solid state. If taken mixed with the food or immediately after a meal, and especially a meal of fatty substances, its action may be greatly retarded, and hence even excessive doses may under such circumstances fail to act poisonously. In like manner, if the food contain a large proportion of tannin, an insoluble tannate of strychnine will be formed and the action of the poison mitigated or prevented. As a general rule, the more rudimentary or the more feeble the nervous system is, the more readily it is acted upon by strychnine; thus females and children are disproportionately affected by it, notwithstanding the rapidity with which it is eliminated with the urine of the latter. On the other hand, old persons are very susceptible to the action of small doses, perhaps because the medicine is in them slowly excreted by the kidneys. It would appear that sleep retards the poisonous action of the medicine; it, at all events, restrains an open manifestation of it by spasm, etc., just as perfect repose in man or animals under the toxic operations of the drug tends to prevent spasm, while excitement is apt to develop or to aggravate it. Active disease of the central portions of the brain or of the spinal cord induces an exaggerated morbid action under the administration of strychnine, but old paralytic disorders are not affected by it. It aggravates the functional disturbances of tetanus.

When strychnine acts poisonously but gradually, owing to the moderate dose taken or to its slow absorption from the stomach, the patient complains first of general uneasiness, restlessness, soreness and heaviness of the limbs, and stiffness of the joints and muscles, particularly of those of the chest and lower jaw; and these effects are succeeded by spasmodic symptoms. When the dose has been large and the conditions are favorable to its rapid absorption, the phenomena may be clonic convulsions or violent muscular twitchings, which, with the accompanying sensation, have been compared to the effects of an electric shock. Whether rapid or slow in their access, these phenomena are excited and intensified by all external stimuli. They are succeeded by tetanic muscular spasms, during which the arms are rigidly bent and the legs extended, the hands being clenched and the feet extended and arched, the lower jaw firmly fixed against the upper, and the body arched forward. The rigid contraction of the respiratory muscles renders breathing laborious or even temporarily suspends it, and, as a consequence of the immobility of the chest, the blood accumulates in the veins and gives a livid color to the skin. The pulse is rapid and unequal both in volume and force, and the heart-beat is also rapid and fluttering. The retracted corners of the mouth disclose the set teeth, and foam issues from between them, while the staring eyes with dilated pupils and the contracted brows give to the countenance an expression of anguish mingled with fright. The mind generally remains unaffected, and pain is not often complained of. The convulsions may be altogether tonic, and so continue without interruption until death, but more usually they are clonic also, and are interrupted by intervals of calm, or rather of exhaustion. But during such intervals the slightest stimulus may suddenly renew them, but superficial contact rather than firm pressure. Generally the spasms grow less violent, but not so the disorder of the circulation and the exhaustion of muscular power; they become more and more marked until death, which may be due immediately to asphyxia or to asthenia, according as life terminates during a paroxysm or not.

In fatal poisoning by strychnine death may take place within five minutes, and is hardly ever delayed more than five or six hours. Even when poisonous doses are not followed by death, their effects may continue to be observed in extreme fatigue and exhaustion, paralysis of the bladder, and sometimes muscular stiffness and neuralgic pains of several days' duration.

The smallest fatal dose of nux vomica on record is said to have been 3 grains of the alcoholic extract and of strychnine taken by an adult $\frac{1}{12}$ grain (Husemann). Taylor, however, says: "A fatal dose of strychnine for an adult may be assigned at from $\frac{1}{2}$ grain

to 2 grains." A child between two and three years of age died in four hours from taking $\frac{1}{16}$ grain of strychnine. On the other hand, recovery has taken place after the ingestion of 3, 4, and even 7 or 8 grains, and in one case 8 grains of nitrate of strychnine and 12 grains of the pure alkaloid were taken without fatal effect. In the last instance the poison was suspended in bitter-almond water holding in solution 10 grains of acetate of morphine, and swallowed after a meal consisting of porridge and cranberries; chloroform also was inhaled. The natural effects of the strychnine seem to have been prevented by the mass of food in the stomach, by the precipitation of the strychnine as an insoluble tannate formed with it by the tannic acid of the cranberries, and finally by the antagonistic action of the hydrocyanic acid and the morphine (Tschepke, *Deutsche Klinik*, No. 10, 1861). The mode of access and the course of the symptoms are not always the same; e. g. muscular rigidity may first be felt in the spine and attended with neuralgic pains of the trunk or limbs, or the attack may commence abruptly with shrieks as of pain or alarm, or it may set in with giddiness, insensibility, or clonic convulsions, or, again, among the earliest symptoms vomiting may occur.

After death caused by strychnine cadaveric rigidity is usually marked with opisthotonos, clenching of the hands, and flexion of the arms across the chest. The face is usually pale, but sometimes livid. The muscles are rigid, and all the internal organs are gorged with dark blood, the cerebral and spinal membranes not more so nor more uniformly than the rest; the latter may contain a serous effusion; the heart may either be contracted, dilated, or natural. The urinary bladder is generally contracted. It is remarkable that the muscular rigidity may persist for months after death. These lesions indicate the effects rather than the mechanism of strychnine-poisoning. But they agree with the symptoms in showing that the cause of death by this poison is primarily asphyxia produced by rigidity of the muscles of respiration. This view does not exclude, as a possible factor in producing the result, exhaustion of the heart or spasm of that organ.

Medical Uses.—Strychnine was first employed medicinally in the treatment of *paralysis*, and continues to be used for this affection more than for any other. But it is not equally beneficial in all forms of the disease. As already stated, it is apt to aggravate those paralyzes which depend upon a recent central lesion, but it is appropriate in the same cases when the acute stage has passed and the symptoms remain stationary. In such cases the paralyzed muscles are the first to exhibit the specific action of the medicine. It is now demonstrated, as it was long ago observed, that strychnine is most efficient in the cure of functional paralyzes, whether depending directly upon anemia of the spinal cord or upon general exhaustion. Such are cases due to venereal excesses, hysteria, intense mental emotion, concussion of the spinal marrow, abuse of opium or alcohol, lead-poisoning, gout, rheumatism, etc. It is claimed by some (Jewell, *Practitioner*, xxvii. 377) that even in advanced *myelitis* this medicine will cause improvement after the failure of other remedies. Contrary to what would have been expected on theoretical grounds, the efficient doses were large. *Diphtherial paralysis* is, more than any other form, benefited by strychnine, whose special stimulus co-operates with that of electricity, mechanical excitants, tonics, nutrients, etc. The semi-paralytic condition sometimes induced by the *bromides* is benefited by this medicine. It is less necessary, yet of very great utility, in *paralysis from lead*. An *ecbolic* action has been ascribed to strychnine on the ground of its having seemed to produce tonic contractions of the uterus and premature delivery of a woman in the eighth month of pregnancy (Lewis Smith, *Med. Record*, xviii. 578).

Although physiological experiments do not lead to the suggestion that strychnine acts upon the peripheral ends of nerves, clinical observation, as in so many other cases, is supposed to have demonstrated what the former method has failed to show. For more than forty years strychnine has been well known to be efficacious in cases of *amaurosis* when applied endermically around the orbit; more recently it has been used by friction and hypodermically, by the instillation of dissolved strychnine in the eye, and also internally. These methods have greatly ameliorated and often cured the disease, not only in cases of purely functional disorder, but of a greater or less alteration of the retina as revealed by the ophthalmoscope. Inflammatory affections of the eye in their active stage are unsuitable for this medication, and so is impairment of vision depending upon intracranial causes, but it is often useful in disorders of accommodation. The greater number of ophthalmic surgeons insist upon the application of the medicine to the neighborhood of the eye, but others admit that it is equally efficacious wherever introduced. The latter are probably right. It has been employed with marked success in *night-blindness*.

Nux vomica and also strychnine have been used with unquestionably good results for

the cure of *prolapsus of the rectum* by enema, by hypodermic injection (Weber, *Med. Record*, xviii. 682), and by their application to the blistered skin. *Paralysis of the bladder*, occasioning either retention or incontinence of urine, and the latter affection in the form of *nocturnal incontinence* in children, has frequently been cured by the use of strychnine by the mouth, sometimes by injecting a solution of it into the bladder, and again by the hypodermic injection of nitrate of strychnine. *Sexual impotence* is often diminished or even cured by this medicine when it depends upon asthenia of the spinal cord or upon general debility. Generally, however, it should form only one element of a complex treatment adapted to the peculiarities of each case. *Saccharine diabetes* is alleged to have been cured by *nux vomica* (*Practitioner*, xxiii. 51); and Brunton claims that it will control the *night-sweats* of phthisis (*St. Bart's Rep.*, xv. 119).

Among spasmodic diseases *tetanus* has been cured by strychnine, contrary to all expectations founded upon the accepted mode of action of the medicine; nevertheless, the method has found few imitators. The same remark is nearly as applicable to *chorea*, and also to *epilepsy*; but in regard to both diseases it may be observed that where the patients are extremely feeble, excitable, and timid, this medicine may well form part of the general plan of tonic treatment which is then indicated, and which includes the administration of quinine and iron. A like statement may also be made respecting various local *spasms*, as that of the *œsophagus*, *facial tic*, etc. It is said that *writer's cramp* has been cured by the hypodermic use of strychnine, and the *vomiting of pregnancy* by its internal use. It is alleged that the medicine has the power of arresting the development and preventing the usual effects of *alcoholic intoxication* (Luton, *Bull. de thérap.*, xcix. 241 : cii. 473; Dujardin-Beaumetz, *Ibid.*, cvi. 1). These physicians have not feared to use hypodermic injections of 5 Mgm. or gr. $\frac{1}{12}$ in cases of *delirium tremens* and *mania-a-potu*, without adverting to the fact that the affections in question terminate spontaneously in cure in nearly all uncomplicated instances if treated with exercise and well-seasoned food. It is one of the numerous remedies which have seemed to moderate *hay fever*. It has been known to cure *facial neuralgia*, *lead colic*, *dysmenorrhœa*, etc., but its efficacy is too inconstant to inspire confidence. There is one form of neuralgia, *gastralgia*, in which it is often of signal benefit, doubtless more by its power as a bitter tonic than as a nervine. The cases in which it is most useful are those in which the *gastralgia* is associated with *gastrodynia* attended by flatulent dyspepsia, eructations, and sometimes vomiting of food, along with habitual constipation. In some of these cases strychnine, or still better, *nux vomica*, should be combined with antacids and stimulant carminatives. It is, on the whole, best suited to combat the element gastric debility, with whatever symptoms that condition may be associated. Its tonic action upon the intestine renders *nux vomica* and strychnine appropriate remedies for *constipation* depending upon atony of the bowel. But for this purpose it should be prescribed in small doses taken immediately after meals, or should be associated with aloes, rhubarb, and soap, or with the first only, in a pill, which is most conveniently taken at bedtime. A similar mode of action makes it one of the best remedies for the so-called *spasmodic obstruction* of the bowel, which is really, in most cases, constipation with fecal accumulations at one part of the intestine and flatulent distension at another. *Tympanites* from intestinal debility is favorably influenced by this medicine, especially if associated with lime-water or some anti-fermentative, as salicylic acid. On the other hand, *chronic diarrhœa* and *dysentery*, affections in which the discharges are apt to be prolonged by the exhausted state of the bowel, are often benefited by *nux vomica* or strychnine. The latter is alleged to have been found useful in *epidemic cholera*. It is also reported to act as a *vermifuge*. Finally, it has been used with alleged benefit in various forms of *dyspnoea* depending upon pulmonary and cardiac obstruction, including *emphysema*, *bronchitis*, and, along with digitalis, in cases of *fatty heart* (Fothergill).

Administration.—The first dose of strychnine should not be greater than from $\frac{1}{20}$ to $\frac{1}{12}$ grain (Gm. 0.003–0.005); as a general rule, it is better to begin with $\frac{1}{30}$ grain (Gm. 0.002), and cautiously increase the dose until a slight manifestation of its specific effects occurs or until the object of its administration is attained. It is usually prescribed in pills of bread-crumbs or of confection of roses, care being taken to mix the mass thoroughly and divide it accurately. A convenient form, which its bitterness alone renders objectionable, is to dissolve 1 grain of strychnine in 2 fluidrachms (Gm. 0.06 in Gm. 8) of rectified spirit with the aid of 2 minims of sulphuric, acetic, or muriatic acid, so that every 10 minims of the solution shall contain gr. $\frac{1}{12}$ (Gm. 0.005) of the salt of strychnine. For hypodermic injection a solution of 4 grains of sulphate or muriate of strychnine in a fluidounce of water is used (Gm. 0.26 in Gm. 32). Each minim contains

the $\frac{1}{120}$ grain (Gm. 0.0005) of the salt. 2 minims or $\frac{1}{60}$ grain (Gm. 0.001) of strychnine may be used as a primary dose. In all cases in which strychnine is used the modifying operation of idiosyncrasies and of the existing disease must be regarded.

Treatment of Poisoning by Strychnine: As in the case of other poisons taken into the stomach, so in poisoning by strychnine, free vomiting should be produced by mustard and warm water, or, as has been found successful in one case, by the hypodermic injection of $\frac{1}{4}$ grain (Gm. 0.02) of apomorphine, after which the bowels should be purged with castor oil, croton oil, or a saline laxative. When asphyxia threatens, artificial respiration should be resorted to. As mechanical antidotes which retard the absorption of the poison, lard, sweet oil, and milk have been used with apparent success immediately after the poison was taken and before its spasmodic action had been developed. Animal charcoal, and also tannin, have been used with the same view. Of the other alleged antidotes, all are more or less sedatives of the nervous system, and therefore antagonists of the spasm produced by the poison. The first of these is the medicine which has been so much employed in the treatment of tetanus, *opium*, or *morphine*, and from which, *a priori*, so much was to be expected. But experimentally and clinically the expectation has proved to be unfounded. Opium and its salts are useless in strychnine-poisoning, however efficient they may be in relieving the symptoms produced by the alkaloid when its medicinal operation is but slightly exceeded, or in delaying the absorption of the poison, and therefore the manifestation of its symptoms. *Aconitine* and *woorara* are also regarded as physiological antidotes to strychnine, but we are unacquainted with any instances of their use as such in human poisoning. The same remark applies to *prussic acid*. Moreover, the physiological antagonism of woorara and strychnine has been denied by Vulpian, Brown-Séquard, and others. *Camphor*, internally, is said to have arrested the toxic symptoms. There is more evidence in favor of *chloroform*, which unquestionably has in several cases controlled the spasm and apparently prevented death, while in others it has rendered the phenomena of death less distressing. The antagonism shown by experiments upon animals to exist between *chloral* and strychnine is more or less exhibited in cases of poisoning by the latter. Chloral counteracts the spasmodic effects of strychnine, and thus conserves force, while it gains time for the elimination of the poison. In the case of a woman who had taken 40 Gm. of strychnine (gr. vi.) recovery ultimately took place, and was evidently due to the administration of chloral by the mouth and rectum and hypodermically (Faucon, *Archives gén.*, Jan. 1883, p. 74). Another case, in which the estimated dose of the poison was 5 grains, recovered after the use of chloral hydrate, but apparently in doses quite inadequate to control the action of the strychnine (*Boston Med. and Surg. Jour.*, July, 1881, p. 8). Two cases are reported by Moore (*Med. News*, xli. 566), the one illustrating the virtues of strychnine in chloral-poisoning, and the other (in a dog) of chloral in poisoning by strychnine. (On the relations between the two agents see Husemann, etc., *Amer. Jour. of Med. Sci.*, Apr. 1882, p. 608.) *Nitrite of amyl*, which appears to be more or less antidotal to strychnine in dogs and frogs, does not seem to have been sufficiently tested in poisoning by this substance in man. *Bromide of potassium* is credited with several striking cures of strychnine-poisoning. In three of them the doses of strychnine were very large and the effects characteristic; but repeated doses of the bromide, varying in their totality from 80 grains to $\frac{1}{2}$ ounce (Gm. 5–16), saved the patients. Experiments on animals demonstrate the power of the bromide to prevent or mitigate strychnine spasms. In several cases the bromide has been associated with chloral (*Med. Record*, xix. 208), but the experiments of Husemann (1880) seem to show that the former medicine was superfluous (*Bull. de théor.*, xcix. 429). *Calabar bean* and strychnine appear to be truly antagonistic, in that the one counteracts the operation of the other, provided that their doses and the time of their administration be duly adjusted. But there is great danger that death by asphyxia may be escaped only by encountering the risk of death from exhaustion. In two cases which terminated favorably this untoward result was prevented by the use of stimulants internally and externally. In one of these cases $\frac{3}{4}$ grain (Gm. 0.05) of the extract of physostigma was exhibited three times within an hour, and in the other case 1 grain (Gm. 0.06) in a single dose. These conclusions concerning the efficiency of chloroform, chloral, bromide of potassium, and physostigma have been experimentally confirmed by Husemann (1878). *Tobacco* and *nicotine* have been employed experimentally as antidotes to strychnine, and, on the whole, with not unfavorable results. Whether or not they may be so regarded in a physiological sense, matters little, provided that they save lives which would otherwise be lost. That tobacco has done so is proved by at least four recorded cases. Possibly it may have

acted in part by hastening the elimination of the poison with the urine. The uncertainty and possible danger of these antidotes should exclude them when chloral can be obtained. *Belladonna* and *atropine* have also been suggested as antidotes to strychnine, and a case is recorded in which, atropine having been injected subcutaneously, the patient recovered. $\frac{1}{4}$ grain (Gm. 0.01) was thus used three times at intervals of ten minutes. In two more recent cases recovery was attributed to the administration of atropine (*Phila. Med. Times*, x. 323).

STYRAX, U. S.—STORAX.

Styrax præparatus, Br.; *Styrax liquidus*, P. G.; *Balsamum styracis*.—*Liquid storax*, E.; *Styrax liquide*, Fr.; *Flüssiger Storax*, G.

A balsam prepared from the bark of *Liquidambar orientalis*, Miller, s. *L. imberbe*, Aiton. Bentley and Trimen, *Med. Plants*, 107.

Nat. Ord.—Hamamelaceæ, Balsamifluæ.

Origin.—The tree yielding liquid storax closely resembles the sweet-gum tree of North America (see p. 890), from which it differs in having smooth leaves with obtuse, often three-lobed, and finely serrulate lobes, and in producing smaller heads of fruit. It has been found only in the south-western part of Asia Minor, where it forms forests.

Production.—The extraction of liquid storax was described by Hanbury (1857) from accounts received from S. H. Maltass and Lieut. Robert Campbell. The outer bark is stripped off on one side of the tree, made into bundles, and reserved for the purpose of fumigation. The inner bark is then scraped off with a semicircular or sickle-shaped knife, and thrown into pits until a sufficient quantity has been collected. It is then boiled in water, upon which the resinous matter comes to the surface, and is skimmed off. The boiled bark is next put into hair-sacks and pressed, boiling water being added to assist in the extraction of the resin, or, as it is termed, *yagh*—i. e. oil. According to Maltass, the fresh bark is pressed in strong horsehair bags by means of a wooden lever press, hot water being afterward thrown over the bags, and these subjected to pressure a second time. Dr. McGrath states that the storax is chiefly collected by a tribe of wandering Turcomans called *Yuraks*, and that the liquid resin, separated from the bark by boiling and pressure, is run into barrels.

Description.—Liquid storax has the consistence of thick honey, and is sticky, opaque, and of a gray color, caused by the water which is diffused through it. By long standing it separates a heavier dark-brown (in thin layers transparent) stratum. When heated it becomes thinner and more transparent, the water separating slowly, and when ignited it burns with a bright sooty flame. It becomes harder by age and on exposure, is heavier than water, and has a strong agreeable odor, somewhat resembling that of vanilla. Its taste is pungently balsamic. With the exception of the water and the impurities contained in it, storax dissolves in alcohol, ether, chloroform, and most of the volatile oils. With an equal weight of warm alcohol it yields a turbid gray-brown solution having an acid reaction; when cooled and filtered the solution, on evaporation, yields not less than 70 per cent. of the weight of the balsam in the form of a brown semi-liquid residue, which deposits crystals only after a long time, and which, with the exception of a few floccules, is completely soluble in ether and in carbon disulphide (*U. S., P. G.*). It is insoluble in cold petroleum benzin, but dissolves partly in it while hot, the colorless solution depositing crystals of cinnamic acid and styraein on cooling. Examined under the microscope, storax is seen to consist of minute globules, intermixed with larger drops of water and with tubular crystals of cinnamic acid, and when left on the object-glass feathery crystals of styraein make their appearance.

STYRAX PRÆPARATUS, Br., is storax purified by melting and straining (*F. Cod.*), or by dissolving in rectified spirit (benzol, *P. G.*), filtering, and evaporating the solvent. It has a brown-yellow color, is semi-transparent or transparent in thin layers, and otherwise resembles the crude balsam.

Constituents.—E. Simon (1839) obtained from this balsam styrol, cinnamic acid, styraein, and two resins. In addition to these, W. von Miller (1876–77) found a little benzoic acid, cinnamic ethyl, and a fragrant compound melting at 65° C. (149° F.), probably ethyl vanillin; in larger proportion were found the alcohol storesin in two modifications—the cinnamic ether of this alcohol and cinnamate of phenylpropyl. *Styrol* or *cinnamene* has the composition $C_{10}H_{8}$, and is obtained by distilling storax with water. The yield is very variable. It is a colorless, thin liquid, very refractive to light, and of a very fragrant odor and burning taste. It has been artificially obtained by heating acetylene gas, and from ethyl-benzol bromide by heating it with baryta. Its specific gravity is

0.924, and it boils at 146°C . (294.8°F .); but when heated to 200°C . (392°F .) it is rapidly converted into a polymeric compound, *metacinnamene*, which is a colorless, amorphous, tough solid of the specific gravity 1.054, insoluble in alcohol and ether, and reconverted into styrol when distilled. *Cinnamic acid* (see page 1055) may be obtained by treating storax with a solution of sodium carbonate and precipitating the acid by means of hydrochloric acid. The ethers are obtained from storax previously deprived of cinnamic acid by treating it with hot petroleum benzin, on the cooling of which white or colorless needles are deposited which require repeated treatment with hot benzin. *Styracin* melts at 38°C . (100.4°F .), and after prolonged heating congeals to a transparent mass, in which crystals are formed very slowly. It is *styryl (cinnamyl) cinnamate*, $\text{C}_9\text{H}_7\cdot\text{C}_9\text{H}_7\text{O}_2$, and when in alcoholic solution treated with caustic soda, or when heated with an aqueous solution of soda, is converted into cinnamate of sodium and *cinnam-alcohol*, also known as *styryl alcohol* and *styrone*, $\text{C}_9\text{H}_{10}\text{O}$. This crystallizes in colorless silky needles, has an agreeable hyacinthine odor, melts at 33°C . (91.4°F .), and boils at 250°C . (482°F .). Styracin and cinnamic acid yield with oxidizing agents oil of bitter almonds and benzoic acid, and when styrol is treated with chromic acid and then boiled with water benzoic acid is obtained. After saponifying storax with an alkali, and subjecting the alcohols to fractional distillation, Laubenheimer (1872) obtained a distillate having the properties of *benzyl alcohol*; this is a colorless liquid of a weak but fragrant odor, having the specific gravity 1.06 and the composition $\text{C}_7\text{H}_8\text{O}$. *Storesin*, $\text{C}_{26}\text{H}_{34}\text{O}_3$, is amorphous, melts at 168°C . (β storesin at 145°C .), and dissolves readily in alcohol, ether, petroleum benzin, and potassa, forming with the latter a crystalline compound. Mylius (1882) prepared *styrogenin*, $\text{C}_{26}\text{H}_{34}\text{O}_3$, from that portion of storax which is soluble in boiling benzin; after treating it with an equal weight of sulphuric acid, boiling with water, and washing with ether, white crystals are left which are easily soluble in chloroform, melt at 350°C ., dissolve in cold sulphuric acid, being reprecipitated by water, and yield with warm sulphuric acid a yellowish-red solution, which with water precipitates uncrystallizable resin.

Commercial storax contains from 10 to 20 per cent. of water and from 13 to 18 per cent. of fragments of bark and inorganic impurities (*Pharmacographia*).

Adulterations.—Storax is said to be sometimes adulterated with turpentine. Hager (1874) proposed to detect the adulteration by dissolving the storax in a little warm alcohol and exhausting it with petroleum benzin by agitation. On evaporating the benzin solution the residue should have a bluish opalescence and an agreeable odor, while if turpentine be present the color will be yellowish and the odor of turpentine will be apparent.

Allied Products.—*Cortex thymiamatis*. This is the bark from which storax has been obtained. It is in brown foliaceous cakes, consisting of thin pieces of bark and having the odor of storax.

STYRAX CALAMITA. As now found in the market, it consists of sawdust mixed with liquid storax, and contains numerous minute crystals of styracin. The drug known by this name in ancient times and during the last century was a solid balsamic resin, most likely obtained from *Styrax officinale*, *Linne*, which is indigenous to Western Asia and South-eastern Europe. This is no longer an article of commerce.

Off. Prep.—Tinct. benzoini comp., *U. S., Br.*

History.—The tree from which storax is derived being indigenous to the countries bordering on the Levant, its juice attracted attention from an early period. The storax of Celsus, Pliny, Galen, and Paulus Aegineta is taken to be a solid resin; it was classed by them with the aromatics and balsams, particularly with myrrh, frankincense, and galbanum, and they attributed to it stimulant, cleansing, astringent, and discutient properties, and stated that it was used medicinally in the treatment of coughs, catarrhs, defluxions, and menstrual disorders. But Dioscorides, who was a contemporary of Celsus, states expressly that one variety of storax was liquid, although it is not clear that it was so in its natural condition. The true styrax, or liquidambar, is said to have been first described by Aëtius and by Paulus Aegineta in the sixth and seventh centuries respectively. In the thirteenth century Ibn Baithar stated, on the authority of Hobaisch, that storax is useful for pains in the chest and coughs and for catarrhs, that it controls diarrhoea and flatulence, that externally it is of special service in the treatment of ulcers, and that when mixed with oil it cures the itch and both moist and dry eruptions of the skin.

Medical Action and Uses.—The medicinal action and uses of this substance are almost identical with those of copaiba, like which it was formerly employed in the treatment of chronic catarrhs, particularly of the lungs, but also to some extent in similar affections of the digestive and urinary organs, and especially in *gonorrhœa*. It has

been highly recommended as a dressing for ulcers following *frost-bite*. Within a few years its use as a remedy for *scabies* has been revived. As of old, it is mixed with olive oil for this purpose; a mixture of 1 part of storax with 2 or 3 parts of oil is rubbed diligently into the affected parts, and in the course of 12 hours a warm bath with soap is used, after which the skin is again covered with the liniment. This treatment generally suffices for a cure in nearly all of the cases. It is convenient for its cheapness, as well as for its acceptableness, particularly when balsam of Peru is added to the storax in the proportion of about one-fourth. The latter ingredient improves the odor of the mixture. Of 124 cases of itch treated by Unna with styrax frictions, nine are said to have had albuminous urine during or immediately after the treatment, the albumen varying in proportion from one-tenth to one-half. On the successive application of heat and nitric acid the precipitate was apparently albuminous; but the counter-proof of attempting its solution with alcohol, which would have dissolved a possible resinous deposit, does not seem to have been tried. (Compare *Virchow's Archiv.*, lxxiv. 424, and Lassar, *ibid.*, lxxvii. 558.) The following formula is recommended as more efficient than the mixture described above: ℞. Liquid storax ʒij; Alcohol fʒij; Olive oil fʒj.—M. S.—For two frictions. The dose of storax internally is from 10 to 20 grains (Gm. 0.60–1.30).

Styracin, or *styrone*, is said to be an antiseptic and deodorizer. When pure it is slightly irritating to raw surfaces, but dissolved in 6 parts of oil or water it is no longer so. 1 part in 12 forms a convenient solution for an antiseptic dressing (*Boston Med. and Surg. Jour.*, Mar. 1880, p. 249).

SUCCI.—JUICES.

Sucs végétaux, Fr.; *Pflanzensäfte*, G.

These preparations are made by bruising the fresh drugs, expressing them forcibly, and mixing the expressed juices with a definite proportion of alcohol for preservation. They must necessarily vary in the amount of their active constituents, and perhaps more so than the dried and carefully-preserved drugs. They have been dismissed from the U. S. P., and tinctures of fresh herbs admitted in place thereof. (See TINCTURÆ HERBARUM RECENTIUM.)

SUCCUS BELLADONNÆ, Br.—JUICE OF BELLADONNA.

Suc de belladone, Fr.; *Belladonnasaft*, G.

Preparation.—Take of fresh leaves and young branches of *Belladonna* 7 pounds; Rectified Spirit a sufficiency. Bruise the belladonna in a stone mortar, press out the juice, and to every 3 measures of juice add 1 of the spirit. Set aside for 7 days, and filter. Keep it in a cool place.—Br.

Medical Uses.—The dose of this preparation is from 5 to 15 minims (Gm. 0.30–1).

SUCCUS CONII, Br.—JUICE OF CONIUM.

Juice of hemlock, E.; *Suc de grande ciguë*, Fr.; *Schierlingsaft*, G.

Preparation.—Bruise fresh *Conium*-Leaves, press out the juice, and to every 3 measures of juice add 1 of spirit. Set aside the liquid for 7 days, and filter. Keep it in a cool place.—Br.

Medical Uses.—The dose of juice of hemlock is stated at from $\frac{1}{2}$ to 1 fluid-drachm (Gm. 2–4), but the characteristic effects of the drug are not manifested in the slightest degree by doses of less than 2 drachms (Gm. 8), and ordinarily they are not well marked by less doses than $\frac{1}{2}$ ounce (Gm. 16). Doses of 1, 2, or even 4 ounces (Gm. 64–128), have been given without occasioning alarming symptoms. But in whatever dose the medicine is administered, it should not be increased beyond the point at which it begins to render deglutition and voluntary movement imperfect. This preparation is relatively less powerful in children than in adults.

SUCCUS HYOSCYAMI, Br.—JUICE OF HYOSCYAMUS.

Suc de jusquiame, Fr.; *Bilsensaft*, G.

Preparation.—Bruise fresh leaves and young branches of *Hyoscyamus* in a stone

mortar, press out the juice, and to every 3 measures of juice add 1 of spirit. Set aside for 7 days, and filter. Keep it in a cool place.—*Br.*

Medical Uses.—The *dose* is from $\frac{1}{2}$ to 1 fluidrachm (Gm. 2-4).

SUCCUS SCOPARII, *Br.*—JUICE OF BROOM.

Suc de genêt à balais, Fr.; Besenginstersaft, G.

Preparation.—Bruise fresh Broom-Tops in a stone mortar, press out the juice, and to every 3 measures of juice add 1 of spirit. Set aside for 7 days, and filter. Keep in a cool place.—*Br.*

Medical Uses.—This juice may be prescribed in *doses* of 1 or 2 fluidrachms (Gm. 4-8).

SUCCUS TARAXACI, *Br.*—JUICE OF DANDELION.

Suc de pissenlit, Fr.; Löwenzahnsaft, G.

Preparation.—Bruise fresh Dandelion in a stone mortar, press out the juice, and to every 3 measures of juice add 1 of spirit. Set aside the liquid for 7 days, and filter. Keep it in a cool place.—*Br.*

Medical Uses.—This preparation is a convenient form for the administration of dandelion, but it may be surmised that even the small proportion of alcohol which it contains may impair its virtues in those hepatic derangements for which dandelion is a reputed remedy. The *dose* is from 2 to 4 fluidrachms (Gm. 8-16).

SULPHUR, *U. S., Br., P. G.*—SULPHUR.

Soufre, Fr.; Schwefel, G.

Symbol S. Atomicity bivalent, quadrivalent, and sexivalent. Atomic weight 32.

Official Forms of Sulphur.—1. SULPHUR (SULFUR) SUBLIMATUM, *U. S., Br., P. G.*; Flores sulphuris.—Sublimed sulphur, Flowers of sulphur, *E.*; Soufre sublimé, Fleur (Crème) de soufre, *Fr.*; Schwefelblumen, Schwefelblüthe, *G.*—Sulphur sublimed and condensed in powder.

2. SULPHUR LOTUM, *U. S.*; Sulfur depuratum, s. Flores sulfuris loti, *P. G.*—Washed sulphur, *E.*; Soufre lavé, *Fr.*; Gereinigter Schwefel, *G.*—Sublimed sulphur thoroughly washed with water.

3. SULPHUR (SULFUR) PRÆCIPITATUM, *U. S., Br., P. G.*; Lac (Magisterium) sulphuris.—Precipitated sulphur, Milk of sulphur, *E.*; Soufre précipité, Magistère (Lait) de soufre, *Fr.*; Schwefelmilch, *G.*

Origin.—Sulphur is a constituent of the volatile oils of mustard, garlic, and asafetida, and of albumen and other proteids. It is found in many mineral waters as sulphuretted hydrogen and in the form of sulphates, and is widely distributed in the mineral kingdom in combination with metals, forming iron pyrites, FeS_2 , galena, PbS , blende, ZnS , black antimony, Sb_2S_3 , cinnabar, HgS , and other sulphides, and as sulphate in gypsum, heavy spar, and many other minerals. But sulphur is most abundantly obtained from *native sulphur*, which is found in volcanic countries. Beds of native sulphur have been discovered in California, Nevada, Utah, and other parts of the Western United States, in Mexico, the West Indies, etc.; the chief supply of sulphur, however, comes from Italy, where extensive beds are worked near Latera and Scrofano, and from the provinces of Girgenti, Caltanissetta, Catania, and Palermo in the island of Sicily. Sulphur-beds on the surface of the earth are called *solfatare*, and when they are found underground are known as *solfifere*. The latter are the most important, and yield nearly the whole of the commercial sulphur.

Extraction and Purification.—Sulphur is obtained in Sicily by melting it from the mineral in semicircular pits called *calearoni*, which have a diameter of about 30 feet and a depth of about 8 feet, and are internally covered with a layer of gypsum. The bottom is inclined toward one side, which has an opening, closed during the operation with a thin wall of gypsum. The pit is filled with the mineral, and this is heaped up above so as to form an obtuse cone, the whole being covered first with a layer of powdered sulphur ore, and finally with a stratum of spent ore in powder. Fire is now applied to the heap, and after an hour all openings are closed until, after about nine days, the melted sulphur begins to collect on the floor of the pit. Through a small opening made into the gypsum wall the melted sulphur is removed two or three times a day and run into moistened

moulds made of poplar wood, where it solidifies in the form of blunt pyramids, in which condition it enters commerce. The *rough sulphur* thus obtained contains from 3 to 4 parts of earthy impurities, which are removed by distilling the sulphur from iron retorts and conducting the vapors into large brick chambers, where they condense in the form of a fine powder, which is from time to time removed before the condensing-chamber becomes too hot, and constitutes *sublimed sulphur*. If, however, the operation is not interrupted, the brick walls of the chamber become hot enough to melt the sulphur, which is run into wooden moulds. The cylindrical pieces thus obtained enter commerce as *brimstone* or *roll sulphur*.

In Nevada the sulphur ore is placed in upright cast-iron retorts, in shape resembling a blast-furnace; superheated steam is admitted and the pressure raised to about 70 pounds to the square inch; the pressure is slowly reduced to 50 pounds as the melted sulphur flows through a grate into a receiving-pan, where mechanical impurities are allowed to subside, the sulphur being run into large cylindrical moulds, and after cooling broken into irregular lumps before it is refined.

Sulphur is also obtained from pyrites by a process of roasting in heaps or in suitable furnaces built for the purpose, a portion of the sulphur being burned in the operation.

In 1877 the United States imported 96,236,448 pounds of crude sulphur, 2,622,600 pounds of roll sulphur, and 260,600 pounds of sublimed sulphur; and in 1883 respectively 211,769,600 pounds, 258,340 pounds, and 177,250 pounds.

Preparation.—**SUBLIMED SULPHUR.** The process by which this is procured has been described above. The other official forms of sulphur are prepared as follows:

WASHED SULPHUR. Sublimed sulphur 12 parts (24 oz. av.); water of ammonia 1 part (2 oz. av. or 2 fluidounces); water a sufficient quantity. Add the sulphur to 12 parts (24 oz. av. or 23 fluidounces) of water previously mixed with the water of ammonia, and digest for 3 days, agitating occasionally. Then add 12 parts (24 oz. av.) of water, transfer the mixture to a muslin strainer, and wash the sulphur with water until the liquid running from the strainer ceases to produce a precipitate in test solution of chloride of barium. Then allow it to drain, press the residue strongly, dry it at a very gentle heat, and pass it through a No. 30 sieve.—*U. S.* The P. G. orders for 10 parts of sublimed sulphur 7 parts of water and 1 part of ammonia-water, the mixture to be macerated for a day. Prolonged digestion is unnecessary for the removal of the free acid, but it is important that after thorough washing the sulphur be well dried to prevent its slow oxidation.

PRECIPITATED SULPHUR. Sublimed sulphur 100 parts (2 pounds av.); lime 50 parts (1 pound av.); hydrochloric acid, water, each a sufficient quantity. Slake the lime, and make it into a uniform mixture with 500 parts (10 pounds or 9½ pints) of water. Add the sulphur, previously well dried and sifted, mix well, add 1000 parts (20 pounds or 19 pints) of water, and heat the mixture to boiling over a fire for 1 hour, stirring constantly and replacing the water lost by evaporation. Then cover the vessel, allow the contents to cool, pour off the clear solution, filter the remainder, and to the united liquids add, gradually, hydrochloric acid previously diluted with an equal volume of water, until the liquid is nearly neutralized, still retaining, however, an alkaline reaction. Collect the precipitate on a strainer, and wash it with water until the washings are tasteless. Then dry it with a gentle heat.—*U. S.*

The British Pharmacopœia uses 5 oz. of sulphur and 3 oz. of slaked lime, but directs the decanted and filtered solution to be mixed with hydrochloric acid until the mixture acquires an acid reaction.

In the processes described hyposulphite and sulphide of calcium are first produced, from which, on the addition of an acid, sulphur is precipitated. Both formulas direct too large a quantity of lime, resulting in a corresponding waste of hydrochloric acid, but the second formula employs nearly the theoretical quantity of sulphur. In order to obtain good results it is advisable to dissolve in the lime as much sulphur as can be taken up, the reaction taking place as follows: $3\text{CaH}_2\text{O}_2 + 6\text{S}_2$ yields $2\text{CaS}_3 + \text{CaS}_4\text{O}_3 + 3\text{H}_2\text{O}$. Therefore, 168 parts of burned lime or 222 parts of slaked lime require 384 parts of sulphur, or 50 parts of the calcium compounds need respectively 115 and 87 parts of sulphur. It is, however, advisable to employ an excess of sulphur, the undissolved portion of which may be utilized in a subsequent operation; for 1 pound of lime 2½ or 2¾ pounds, and for 1 pound of slaked lime 1¾ pounds, of sulphur should be used. The resulting liquid has a dark orange-red color. Diluted hydrochloric acid should now be added in a thin stream and with continued stirring, when the calcium pentasulphide will be decomposed, calcium chloride remaining in solution, while sulphur is precipitated and hydrosulphuric

acid is liberated, which should be carried off through a chimney. This reaction occurs according to the equation $2\text{CaS}_5 + 4\text{HCl} = 2\text{CaCl}_2 + 4\text{S}_2 + 2\text{H}_2\text{S}$. If the acid be added with the precaution that the liquid retains its alkaline reaction, calcium sulphhydrate, $\text{Ca}(\text{HS})_2$, will remain in solution, and with it any arsenic which may have been present in the sulphur or in the acid; but in the presence of iron black ferrous sulphide will be precipitated with the sulphur, and impart to it a dark-gray color. The latter impurity may be easily removed by washing first with water, followed by dilute hydrochloric acid, and this again by water.

Operating in this manner, as directed by the U. S. P., the solution will become colorless, but the calcium hyposulphite will not be decomposed. The further addition of acid will decompose this compound, sulphur being liberated, together with sulphur dioxide (sulphurous acid), and the latter, by reacting with the sulphydric acid, will liberate an additional quantity of sulphur, with the formation of water. The result of the entire complicated reaction is expressed by the equation $2\text{CaS}_5 + \text{CaS}_2\text{O}_3 + 6\text{HCl} = 6\text{S}_2 + 3\text{CaCl}_2 + 3\text{H}_2\text{O}$. It will be observed that by acidulating the solution of lime and sulphur, as directed by the British Pharmacopœia, a larger amount of precipitated sulphur is obtained; but it was shown by Fordos and Gélis (1851), and by Berthelot, that that resulting from the hyposulphite is soft and only partially soluble in carbon disulphide. Arsenic, if present in the lime solution, will separate as yellow sulphide of arsenic. If the hydrochloric acid is replaced by sulphuric acid, the precipitated sulphur is contaminated with calcium sulphate; it has been proposed to restrict the appellation *læc sulphuris* to this preparation, which is often demanded in Great Britain as milk of sulphur.

Properties.—Sulphur exists in several modifications, and is either *crystalline* and soluble in carbon disulphide, *amorphous* and insoluble in the same liquid, or *soft* or *oily* at common temperatures, and either soluble or insoluble in this menstruum. When sulphur is fused and kept near the temperature of 90°C . (194°F .), octahedral or rhombic crystals are formed, fusing at 115°C . (239°F .); but if the crust which forms on cooling is broken and the liquid sulphur poured out, the vessel will afterward be filled with long oblique prisms, which melt to a yellowish liquid at 120°C . (248°F .). On gradually increasing the heat to near 180°C . (356°F .) sulphur becomes brown, and ultimately black, opaque, and very viscid. If the heat be continued, the mass liquefies again at 260°C . (500°F .), and at about 450°C . (842°F .) is converted into orange-brown vapors. On agitating sublimed sulphur with carbon disulphide about two-thirds of it are dissolved, while the remainder is amorphous and remains undissolved. The different varieties of sulphur differ also in specific gravity, that of amorphous and soft sulphur being 1.96, of prismatic sulphur 1.98, and of octahedral sulphur 2.05; this last variety is more stable than the other two, which are under various circumstances converted into it. Heated in the air, sulphur ignites at about 150°C . (302°F .), and burns with a blue flame to sulphurous anhydride or sulphur dioxide, SO_2 . This gas always contains a small quantity of the trioxide or sulphuric anhydride, SO_3 , according to Lunge and Salathé (1883), if the combustion takes place in dry air, the amount being 2.5 or 2.8 per cent., and the quantity being increased in the presence of ferric oxide. The two oxides named are the only oxygen compounds which have been obtained in the isolated state, though several others are known in combination, of which the most important is hyposulphurous (thio-sulphuric) acid. (See SODII HYPOSULPHIS.) The other oxygen compounds of sulphur are as yet only of scientific interest; they are *hydrosulphurous* (H_2SO_2), *dithionic*, *trithionic*, *tetrathionic*, and *pentathionic acids*, and the last four contain, in combination with a bivalent basylous radical, 6 atoms of oxygen, and respectively 2, 3, 4, and 5 atoms of sulphur. These four acids, when liberated from their salts, are readily decomposed into sulphuric and sulphurous acids, the last three separating also sulphur.

Sulphur combines also with most of the non-metallic and metallic elements, forming sulphides, the most important of which to the pharmacist are the sulphides of antimony, mercury, iron, potassium, ammonium, and hydrogen. When treated at an elevated temperature with volatile and fixed oils, it dissolves, and forms with the fats compounds which were formerly known as *balsams of sulphur*. Sulphur is insoluble in water, but dissolves in hot solutions of the fixed alkalies and alkaline earths, forming sulphides, and is somewhat soluble in hot absolute alcohol, ether, chloroform, and benzol, being deposited on cooling in crystals.

SUBLIMED SULPHUR is a yellow or somewhat greenish-yellow, slightly gritty powder, which is free from odor and taste, or generally has a slight sulphurous odor and a faint acidulous taste, and has a slight acid reaction to litmus. To heat and solvents it shows the behavior described above.

WASHED SULPHUR has the same appearance and behavior as the preceding, except that it is entirely inodorous and nearly tasteless, and does not change the color of litmus-paper, which properties are demanded by the Br. P. for its sulphur sublimatum.

PRECIPITATED SULPHUR is a yellowish-white or grayish, very fine powder, free from grittiness and from the odor of sulphuretted hydrogen, and nearly tasteless. When examined under the microscope it is seen to consist of opaque globules which are free from crystalline matter. It is not altered on exposure to air when kept dry, and on fusion it is converted into ordinary sulphur.

Tests.—Water agitated with washed or sublimed sulphur (*U. S.*), or these varieties of sulphur moistened with water (*P. G.*), should not redden blue litmus-paper; the last is the more delicate test. Pure sulphur should completely evaporate by heat, and when ignited in the air should burn without leaving any fixed residue (clay, gypsum, etc.). The pharmacopœias permit a trace of fixed residue for sublimed and washed, but none for precipitated, sulphur. The latter, if precipitated by sulphuric acid, is more readily miscible with water than pure precipitated sulphur, and leaves on ignition a large amount of fixed residue. For the detection of this and other fixed impurities the *U. S. P.* gives the following additional but unnecessary tests: "If precipitated sulphur be boiled with diluted hydrochloric acid, the liquid filtered, and the filtrate divided into two portions, one portion should not be precipitated by test solution of chloride of barium, and the other portion should not be rendered more than slightly turbid by test solution of carbonate of ammonium with excess of water of ammonia (absence of sulphate of calcium). When digested successively with water, hydrochloric acid, and water of ammonia, these liquids, after filtration, should leave no residue on evaporation (absence of alkalies, alkaline earths, or sulphide)." Sulphur obtained from pyrites usually contains arsenic, which is most conveniently detected, unless present in very minute quantities, by digesting it with 2 parts (*U. S.*) (20 parts, *P. G.*) of ammonia-water, filtering, and adding hydrochloric acid, when yellow sulphide of arsenic will be precipitated; on the further addition of sulphydric acid, arsenious acid, if present, will yield a yellow precipitate of sulphide of arsenic. While arsenious acid may be present in sublimed and in washed sulphur, it is obvious from the above explanation of the process that precipitated sulphur may be contaminated with sulphide, but not with the oxide of arsenic. Very minute quantities of this metal are best detected by Marsh's test. Selenium, which is sometimes present in sulphur, is detected by heating a sample with nitro-muriatic acid, diluting with water, filtering, and concentrating the filtrate, which contains selenious acid, and yields, on the addition of sulphite of sodium, a bright-red or reddish-black precipitate of selenium. Precipitated sulphur frequently has a slight odor of sulphuretted hydrogen, which is more apparent on being warmed; such sulphur acquires a more or less black color when agitated with a solution of acetate of lead; the pharmacopœias give no chemical test, almost complete freedom from odor being sufficient.

Off. Prep.—1. Of sublimed sulphur: Empl. hydrargyri, *Br.*; Emplast. ammoniaci cum hydrargyro, Potassa (sulphurata), Sulphur præcip., Sulphuris iodidum, Ung. sulphuris, *U. S., Br.*

2. Of washed sulphur: Confectio sulphuris, *Br.*; Puly. glycyrrh. comp., Sulphuris iodidum, Unguent. sulphuris alkalinum, *U. S.*

History.—The word "sulphur" is derived, according to some, from *sal*, salt, and *zup*, fire; and according to others, from *solum*, earth, and *zup*, fire. Brimstone is from A.-S. *lyrne*, burning, and *stoun*, stone. Its fumes were very anciently employed to purify bodies, clothing, and dwellings; Hippocrates refers to it in his treatise on the diseases of females; Pliny attributed to it a heating and restorative quality, states that it discusses swellings, and for that purpose may be used in plasters and poultices; that it relieves lumbago when rubbed upon the loins in an ointment; that in combination with resins it removes lichenous and leprous eruptions, and as an electuary moderates dyspnoea and cough with purulent expectoration. Dioscorides, and later Paulus Ægineta, spoke of its virtues in itch. The value of sulphurous mineral waters was well known.

Physiological Action.—*On Vegetables and Animals:* The use of powdered sulphur for limiting fermentation has come down from a remote period, and it has also long been used for destroying parasitic fungi upon plants, as well as parasitic insects upon plants and animals. Recent experiments appear to show that these effects, as well as others which are usually attributed to sulphur, are in reality due to the sulphurous and sulphuric acids with which it is nearly always impregnated or which form by the action of the oxygen of the air upon it. If this view be correct, the therapeutic applications of sulphur will need revision. More than a century ago (1745) Langrish showed that

when the body of a dog was exposed to the fumes of burning sulphur the animal suffered no inconvenience, but all the fleas that infested it were killed. Powdered sulphur given to animals in moderate but repeated doses impregnates the perspiration, the eructations, the feces, and sometimes the expired breath with sulphuretted hydrogen. Larger doses operate as laxatives, and, if continued, occasion diarrhoea, but do not materially affect the intestinal membrane. The flesh of sheep that have eaten food mixed with sulphur tastes and smells of sulphuretted hydrogen.

On Man: In doses of from 20 to 40 grains sulphur occasions soft stools, generally without colic, and the flatus discharged has the odor of sulphuretted hydrogen. The greater part of the sulphur passes unchanged. When small doses are repeated day after day, the exhalations of the lungs and skin have a sulphurous smell, the linen is sometimes stained yellow by the perspiration, and silver articles worn near the skin are blackened by the formation of sulphide of silver. The expired air also, the urine, and the milk contain combinations of sulphur. It has happened, when a course of mercury followed the administration of sulphur, that parts of the skin have been discolored by sulphide of mercury. Sulphur may continue to be used for a long time and in full doses without untoward effects, but, on the other hand, a case has been recorded of a person who took 120 grains of sulphur in wine four or five times a day, and who on the sixth day was seized with nausea, bloody diarrhoea, cramps in the legs, fever, dysury, etc., and for several years suffered from irritable stomach. There can be little doubt that these peculiar symptoms were occasioned by a great excess of free acids in the sulphur, for those acids have been found to be present in the proportion of from 10 to 30 parts in 10,000 parts of ordinary sublimed sulphur. They are the chief source of the increased proportion of sulphates found in the urine of those who use sulphur medicinally. The proportion of uric acid and of urea in this secretion is also said to be increased.

So long as the stomach contains only its normal acid secretions, sulphur undergoes no changes in that organ, but if the gastric liquids are rendered alkaline by disease, sulphuretted hydrogen may be evolved, as it normally is, in the intestinal canal by a reaction between a portion of the sulphur in the food and the alkaline secretions of the liver and pancreas. That such is the case is proved by the odor of the dejections, and, when the medicine has been for some time employed, by that of the cutaneous and pulmonary exhalations also. Even the skin appears to absorb it in some degree, since those who are subjected to frictions with sulphur ointment discharge fetid gas from the bowels. This may, however, possibly arise from the inhalation of the sulphur, which is volatilized at the temperature of the body. Dolan, however, states that he has found sulphur in the milk, sweat, and urine of persons taking it, and that it acts as a mild purgative on nursing infants through the mother's milk (*Practitioner*, xxvii. 170). The laxative action of the medicine can only be explained by its forming compounds with the aforesaid alkaline secretions. Its irritant and laxative operation is doubtless hindered by the coating of undissolved sulphur which lines the bowel. The alkaline compounds of sulphur in the blood appear to be partially converted into sulphates and to be discharged with the urine. The remainder are secreted chiefly in the form of sulphuretted hydrogen by the lungs and the skin. The extreme depression of the circulatory and nervous systems that has occasionally followed the use of sulphur may be attributed to the same compound absorbed from the digestive canal.

Medical Uses.—The most important therapeutic application of sulphur is to the cure of *scabies*. As already stated, it was used for this purpose in ancient times. With in the last generation its efficacy has been greatly enhanced by softening the patient's skin by means of warm baths before the sulphur is applied, and by associating the latter with some substance which, with the aid of friction, mechanically breaks up the burrows of the acari and brings the insects under the poisonous influence of the sulphur. Some writers, even among the most recent, distinctly assert that sulphur is not efficient *per se*, and can cure the itch only when the presence of a free or carbonated alkali favors the formation of a sulphide, which is the true agent of the cure, and hence that all sulphurous itch ointments should contain such an alkaline ingredient. Others affirm that the sulphur in an ointment only acts mechanically, by breaking up the burrows of the itch insect, while the sulphides destroy its life. These writers appear to have overlooked the presence and potency of sulphurous acid in sulphur ointment, as well as to have forgotten the long period in which simple sulphur ointment continued to be an efficient cure for the itch. The greatest dermatologist of the age was not, apparently, of their opinion. Hebra, after referring to the comparative value of several insecticide agents, says of sulphur: "It was found to be equally effectual whether it was used alone or in combination

with potassa, soda, or lime." He also distinctly points out the advantage of there being mixed with the sulphur some coarse and insoluble substance to mechanically rupture the burrows of the acarus and permit the true insecticide to reach at once the insect and its eggs. But as many of the substances used for that purpose irritate the skin, causing artificial vesicular and pustular eruptions, those remedies only should be employed which, without irritating the skin, will destroy the itch insect and its ova. In hospitals this precaution may be less imperative than in private practice, but in all cases irritating ointments should be applied to those parts only, and especially the hands and the feet, which are distinctly the seat of the parasitic eruption.

The first compound sulphur ointment was that of Helmerich (1812-13), and consisted of 2 parts of sulphur, 1 of carbonate of potash, and 8 of lard, which was said to cure the itch in 18 hours when applied by vigorous and repeated friction, aided by warm baths. The method was revived in 1844 by Hebra, whose perfected formula was as follows: $\mathcal{R}$. Flor. sulphuris. Ol. fagi vel cadini. āā ʒvj ; Saponis viridis. Adipis, āā Oj ; Cretæ ʒiv .—M. He, however, employed successfully a much simpler preparation, made of equal parts of flowers of sulphur and powdered soap, reduced to a semi-fluid mass with water. These agents effect a cure in two or three days when duly supplemented by warm baths. Hardy reduced the time of treatment to two hours. The patient was first rubbed for half an hour with soft soap, and placed in a warm bath for half an hour, the skin being again thoroughly rubbed, after which he was vigorously anointed with Helmerich's ointment or with one composed of 1 part of carbonate of potassium, 2 parts of sublimed sulphur, and 12 parts of lard. The method variously ascribed to Bourguignon and to Vlemingx consisted in the use of the following lotion: $\mathcal{R}$. Calcis vivæ lb. j ; Sulphuris citrini lb. ij . Boil with 20 pints of water until reduction to 12 pints. When cold, filter. The patient is immersed in a warm bath, and for half an hour rubbed with flannel cloths and potash soap, and is allowed to remain for another half hour in the bath. During the third half hour he is again rubbed vigorously with flannel dipped in the solution of sulphuret of calcium, and passes the fourth half hour in the bath. Any particles of sulphur adhering to the skin may be washed off with cold water. This completes the cure. The objection to these methods consists in the harshness of the application and the artificial eruptions they excite.

Sulphur is useful in other diseases of the skin, and especially in *acne*, *alopecia*, *pityriasis*, *syphilis*, and *tinea versicolor*, and in certain cases of *psoriasis*. In the last-named affection, unless very circumscribed, all sulphurous applications are painful and often aggravate the disease. In *tinea versicolor* sulphur baths and the internal use of sulphur waters should be conjoined. In the different forms of *acne* the seat of the eruption should every night be bathed with warm water to soften the skin, after which a paste made with flowers of sulphur and water, or an ointment prepared with equal parts of sulphur, carbonate of potassium, and simple ointment, should be smeared over the affected part and allowed to remain all night. In the morning it should be thoroughly washed off with soft water, with the addition, if necessary, of bran or Indian corn meal, but without soap. A simpler but very efficient plan consists in dusting the skin with pure precipitated sulphur every night, after washing it with soft water. *Tinea tonsurans*, or *trichophyton*, is curable by sulphur ointment after the hair has been closely cropped. *Chloasma*, or *tinea versicolor*, is sometimes cured by drinking sulphurous mineral waters and by baths of the same, but whether by their local or by their indirect action is not easily determined.

The fumes of burning sulphur, conveyed into a wooden chest enclosing all of the patient but his head, have sometimes been used in the treatment, especially of inveterate cases, of cutaneous diseases, such as *eczema*, *psoriasis*, *impetigo*, and *prurigo*, and also for the cure of *rheumatic* and *scrofulous* affections, *paralysis*, *amenorrhæa*, etc. The method, however, sometimes gave rise to great cutaneous irritation, syncope, etc., and is now seldom if ever employed. Sulphurous baths, both natural and artificial, have always enjoyed a great vogue, especially in the treatment of *rheumatism* and *gout* and of some *cutaneous affections*. For the former thermal waters are to be preferred, and for the latter partial douche baths are more efficacious than general baths, and are more useful in limited than in extensive eruptions. Sulphurous mineral waters generally contain earthy and alkaline sulphates, which render them, when taken internally, more or less laxative and diuretic, and therefore depurative, while the sulphurous acid disengaged from them in the body promotes diaphoresis. (See *AQUE MINERALES*.) Probably by the latter operation sulphur is useful as an internal remedy for chronic rheumatism, especially of the muscles and tendons, but not of the joints. It forms an ingredient of the laxative compound known as the "Chelsea pensioner," thus: $\mathcal{R}$. Flowers of sulphur ʒij ; Cream of tartar

3j; Powdered rhubarb 5ij; Guaiacum 5j; Clarified honey lb.j; one Nutmeg, finely powdered.—M. S.—2 large teaspoonfuls to be taken night and morning, and at bedtime a hot alcoholic draught.

In *chronic coughs* with profuse expectoration the virtues of sulphur are sometimes conspicuous. Its reputation in such affections at one time was so great as to obtain for it the title of *balsamum pulmonum*. It was often used for this purpose in the form of the compound liquorice powder, which is now more generally employed as a mild and efficient laxative. It has been claimed that sulphurous mineral waters are curative of certain cases of phthisis (Candellé, *Bull. de therap.*, cii. 305, 366). Undoubtedly, in certain cases they tend to eliminate the bronchitic element of the disease, but nothing more. (Compare Aitken, *Practitioner*, xxxi. 259.) The mildness of the laxative operation of sulphur renders it appropriate in *piles*; for this and similar purposes it is often administered with cream of tartar, of each 1 drachm (Gm. 4), mixed with molasses.

Nebulized sulphurous waters are useful as a local application in *granular pharyngitis* and *laryngitis*, and powdered sulphur itself was long ago recommended to be applied by insufflation to the same parts in *diphtheria* and *croup*, but of its efficacy there is not sufficient proof, at least in the latter disease. In the former, however, there is some reason for believing that finely-powdered or precipitated sulphur applied in this manner has had the effect of rapidly removing the exudation (Stuart, *Practitioner*, xxii. 248; xxiii. 272). It is said that malarial fevers do not prevail where the air is impregnated with sulphurous emanations (D'Abbadie, *Practitioner*, xxix. 466).

Administration.—Sulphur is given as a laxative in the *dose* of from 60 to 250 grains (Gm. 4–15). For other purposes the dose is about 30 grains (Gm. 2). It may be administered in milk, or molasses or other syrup.

SULPHURIS IODIDUM, U. S., Br.—IODIDE OF SULPHUR.

Sulfur iodatum, Ioduretum sulfuris.—*Iodure de soufre*, Fr.; *Jodschwefel*, G.

Preparation.—Washed Sulphur 1 part (1 oz. av.); Iodine 4 parts (4 oz. av.). Rub them together until they are thoroughly mixed. Introduce the mixture into a flask, close the orifice loosely, and apply a gentle heat, so as to darken the mass without melting it. When the color has become uniformly dark throughout, increase the heat so as to produce liquefaction, and incline the flask in different directions in order to return into the liquid any portion of iodine which may have been condensed on the inner surface of the flask. Then withdraw the heat, and, after the liquid has become solid, break the flask, reduce the fused mass to pieces, and keep them in a glass-stoppered bottle.—U. S., Br.

On warming a mixture of iodine and sulphur the two elements unite, and at a somewhat higher heat melt together. The operation is readily performed in an ordinary vial if this is carefully heated by means of a sand-bath. The use of washed sulphur directed by the U. S. P. is an unnecessary refinement in view of the qualities demanded for sublimed sulphur, the trace of acid present in the latter not affecting the quality of the preparation.

Properties.—Thus prepared, iodide of sulphur is a grayish-black mass of a radiated crystalline appearance and with a metallic lustre. It resembles iodine in smell and taste, and on exposure to the air gradually loses iodine. If exposed to a gradually-increased heat it sublimes, the first portion of the sublimate consisting of iodine, and the portion subsequently obtained containing sulphur; only a minute trace of fixed residue should be left. Iodide of sulphur is insoluble in water, but dissolves in about 60 parts of glycerin, and is soluble in carbon bisulphide, on the spontaneous evaporation of which at a low temperature iodine crystallizes first, and afterward rhombic pyramids of *sulphuric iodide* are obtained, having the formula SI_6 (Vom Rath, 1860), and on exposure to the air leaving sulphur in the form of a delicate crystalline skeleton (Lamers, 1861). Alcohol, ether, volatile oils, and cold solutions of potassa and of potassium iodide decompose iodide of sulphur by dissolving the iodine. A similar decomposition is effected by boiling the iodide of sulphur with water, with the vapors of which the iodine passes off, leaving a residue of sulphur amounting to 20 per cent. of the weight of the iodide of sulphur employed; this is recommended as a test of purity by the U. S. P.

Composition.—Sulphur and iodine are employed in the proportion of their atomic weights, the compound being regarded as *subiodide of sulphur*, S_2I_2 . Guthrie (1861) obtained this compound in tabular crystals by acting with subchloride of sulphur, S_2Cl_2 , upon iodide of ethyl, C_2H_5I .

Off. Prep.—Ungu. sulphuris iodidi, Br.

Medical Action and Uses.—This preparation was originally employed in the treatment of tuberculated diseases of the skin in an ointment which contained from 1 part of the iodide in 12 parts to 1 part in 3 parts of lard. It acts as a stimulant or caustic according to the strength of the ointment applied. It is seldom used, chiefly on account of its tendency to become decomposed. (See UNG. PLUMBI IODIDI.)

SUMBUL, U. S.—SUMBUL-ROOT.

Sumbul radix, Br.; *Racine de sumbul*, Fr.; *Sumbulwurzel*, *Moschuswurzel*, G.

The root of *Ferula* (*Euryangium*, *Kauffmann*) *Sumbul*, *Hooker filius*, s. *Sumbulus moschatus*, *Reinsch*. Bentley and Trimen, *Med. Plants*, 131.

Nat. Ord.—Umbelliferae, Orthospermæ.

Origin.—The sumbul-plant is indigenous to Turkestan, Bucharia, Eastern Siberia, and probably to other parts of Central Asia, and was discovered by Fedschenko (1869) in the mountains of Maghian, south-eastward of Samarkand. It is a perennial growing to the height of 8 feet (2.4 M.), and has large, triangular, tripinnate radical leaves and a few small cauline leaves, the upper ones being reduced to sheathing bracts. The flowers are polygamous, and the fruit is about $\frac{1}{2}$ inch (12 Mm.) long, oblong-oval, dorsally compressed, and when ripe is free from oil-tubes, but in the unripe state has in each mericarp four large dorsal and two small commissural vittæ. The root was sent to Western Russia in 1835 as a substitute for musk, and was afterward used in medicine.

Description.—Sumbul-root enters commerce by way of Russia. It is spindle-shaped, simple, about 12 inches (30 Cm.) long, and is met with in transverse segments,

FIG. 290.

Sumbul-Root.

varying in diameter from 1 inch to 4 or 6 inches (2–15 Cm.), and in thickness from $\frac{3}{4}$ inch to 2 inches (2–5 Cm.), occasionally intermixed with pieces scarcely $\frac{1}{4}$ inch (6 Mm.) in diameter. The root is light, of a spongy texture, annulate in the upper part, and below with longitudinal wrinkles, covered with a thin brown bark, is internally whitish, sprinkled with yellowish-brown resinous dots, and consists of white parenchyma and pale-brownish fibro-vascular bundles, which are easily separated, are irregular-wavy, and more numerous near the bark than in the centre. Sumbul-root breaks with an irregular, farinaceous, and fibrous fracture, and has a strong, persistent musk-like odor and a bitter balsamic taste.

Constituents.—The ethereal tincture of sumbul-root, on being evaporated and treated with alcohol, leaves waxy matter behind, and on evaporating the alcoholic solution Reinsch's (1848) *sumbul balsam* is obtained, which on being heated in a narrow tube acquires a green afterward blue color, and subsequently yields oily distillates of a yellow, green, and blue color, and containing umbelliferon. When added to sulphuric acid the balsam acquires a purple color, and after having been heated with potassa it yields to a small quantity of water angelicate of potassium, the potassium salt of *sambulanic acid* remaining undissolved. Valerianic acid is probably likewise contained in the resinous extract. Murawjeff (1853) reported having obtained from sumbul-root an alkaloid, *sumbuline*, yielding crystallizable salts. The chemistry of sumbul-root requires further researches.

Allied Root.—In India a root is employed as sumbul-root which, according to Pereira, differs from the Russian root in being of a closer texture, firmer, denser, and of a more yellow tint. Dymock showed it to be the root of *Dorema Ammoniacum*, which has no musk-like odor.

Off. Prep.—Tinctura sumbul, Br.

Medical Uses.—This root first attracted attention in Russia about 1840 as a specific for cholera—how uselessly the history of that disease demonstrates. Afterward its strong musky odor led to its being prescribed in various functional nervous disorders, including *hysteria* and *delirium tremens*. Its combined resin and essential oil caused it to be employed in mucous profluvia, such as chronic *bronchitis*, *leucorrhœa*, and *gleet*. It is now but little used. The dose of the root in powder is from 10 to 20 grains (Gm. 0.60–1.30).

SUPPOSITORIA.—SUPPOSITORIES.

Suppositoires, Fr.; *Stuhlzäpfchen*, G.

Suppositories are solid medicinal preparations intended to be introduced into the rectum or vagina, and of such a consistence that they will slowly melt at the temperature of the body or liquefy in the presence of moisture. The material best adapted for the vehicle is undoubtedly butter of cacao, since at ordinary temperatures it is sufficiently firm to be handled, and at the same time has such a low fusing-point that it will slowly but completely liquefy after introduction into the rectum. In addition to this, it is not prone to become rancid, and may be mixed with most medicinal substances commonly employed in this form of medication without having its fusing-point lowered. The volatile oils, camphor, carbolic acid, creasote, and chloral hydrate, exert a marked influence upon the consistence of cacao butter, and liquefy with it at a temperature lower than its fusing-point. But even these substances may be added in small quantities without occasioning unusual trouble in preparing the suppositories; if, however, added in full medicinal doses, the cacao butter may be replaced by about 10 per cent. of spermaceti.

In the selection of the base for suppositories the United States Pharmacopœia very properly follows the French Codex, while the British Pharmacopœia employs a mixture of cacao butter and wax, or curd soap with powdered starch or with starch and glycerite of starch. Suet is also occasionally used in Europe for this purpose. Another vehicle, which is more particularly adapted for vaginal suppositories, is a combination of 3 parts of gelatin, 7 of glycerin, and 1 of alcohol, as proposed by H. B. Brady.

The size of suppositories adopted by the different pharmacopœias varies very much, their weight, according to the British Pharmacopœia, being 15 grains; according to the United States Pharmacopœia, 2 Gm. (30 grains); and according to the French Codex, 4, or for children 2, Gm. (30 or 60 grains).

Preparation.—Suppositories are prepared by the following general formula: Mix the medicinal portion with a small quantity of oil of theobroma by rubbing them together, and add the mixture to the remainder of the oil of theobroma previously melted and cooled to the temperature of 35° C. (95° F.). Then mix thoroughly without applying more heat, and immediately pour the mixture into suitable moulds. The moulds, previously made cold, must be kept so by immersion in iced water. All difficulty in removing suppositories from the moulds may be obviated by having the moulds previously dusted with lycopodium. In the absence of suitable moulds, suppositories may be formed by allowing the mixture, prepared as above, to cool, care being taken to keep the ingredients well mixed, and dividing it into parts of a definite weight each, which may be made into a conical or other convenient form for a suppository. Unless otherwise specified, suppositories shall be made to weigh 2 Gm. (30 grains).—*U. S.*

These directions, which agree with those of the U. S. P. 1870, are sufficiently minute for the proper preparation of suppositories having cacao butter for their base. The directions of the British Pharmacopœia when other vehicles are used are given below. In making suppositories with gelatin, this material is well soaked in water, and when thoroughly saturated and softened is melted together with the requisite quantity of glycerin, and the fused mass is mixed with the alcohol containing the medicinal substance in solution or suspension. Since tannin forms an insoluble compound with gelatin, drugs owing their virtue to tannin cannot be combined with this vehicle, which is likewise not well adapted for various salts unless the amount of gelatin be somewhat increased.

To obtain suppositories of a uniform shape, they are generally moulded. The simplest mould is made of thin writing-paper folded into the shape of a cone and having the edge secured with a little sealing wax or paste; after the material has solidified the paper is unrolled. Or the moulds are made of pewter or other suitable metal and suspended in a tray, which is filled with cold water or fragments of ice to thoroughly chill the moulds before the melted mass is poured out. The suppositories will readily congeal, and may be removed by inverting the mould and striking it suddenly on a slab. Moulds have also been made of brass with a number of conical cavities of the desired size and shape, and arranged in such a manner that after the suppositories have congealed the mould may be taken apart either by removing the top portion or the sides, when the suppositories are easily lifted or pushed out by slight pressure. Serviceable suppository moulds may be made by the pharmacist from plaster of Paris, as was suggested by Charles E. Dwight (1872), by pouring the plaster, mixed with water to the consistence of thick cream, into a suitable vessel, and inserting into the soft mass a convenient number of wax supposi-

itories in such a manner that the broad end is near one side, and the suppositories are immersed only to one-half their diameter. When the plaster has set the wax is removed,

the surface is smoothed with a knife, taking care that the edges of each mould be sharp, and small cavities are dug between the depressions. This represents one-half of the mould, the surface of which is well greased, and after replacing the wax the other half is obtained by pouring mixed plaster upon the greased surface to the depth of an inch or more. When hard the two parts can be easily separated, the edges trimmed off, and each part boiled for about an hour in linseed oil, which will prevent the adhesion of the substance to be moulded. The adhesion of suppositories to metallic moulds sometimes causes inconvenience; it is frequently due to the

FIG. 291.

Suppository Mould.

FIG. 292.

Tray for Suppository Moulds.

FIG. 293.

Suppository Mould.

imperfect cleaning or to insufficient chilling of the moulds, and may be prevented by dusting them lightly with lycopodium.

In making suppositories it is of importance that the medicinal ingredients are uniformly mixed with the vehicle, and if not soluble in the latter the rapid congelation of the mixture after it has been poured into the moulds is absolutely necessary. The difficulty thus experienced has led many pharmacists to abandon this method and prepare suppositories by a process rendering fusion of the cacao butter unnecessary. This vehicle is either grated or by means of a sharp knife cut into very thin slices, and mixed by trituration, either in a mortar or on a slab, with the other ingredients; in this condition the mass may be easily rolled out, in the same manner as a pill mass, and cut into the requisite number of pieces, each of which is then shaped into a cone with the fingers or a spatula. Several apparatuses have been constructed by means of which the mass, as obtained by mixing the cold ingredients, may be compressed into conical moulds. The simplest machine for this purpose has been constructed by Prof. Emlen Painter (1878), and is very similar to Remington's machine for compressed pills, figured on page 1166, from which it differs in the greater thickness of the cylinder and in the conical shape of the cavity used for compressing the material.

Special formulas for suppositories are no longer given by the U. S. Pharmacopœia, but the following synopsis explains the composition and manipulation for those which were recognized by the U. S. P. 1870: twelve suppositories are made in each case:

Suppositoria	Medicinal ingredients.	Incorporate with cacao butter.	Add to cacao butter.
Acidi carbolici.	Carbolic acid 12 grains.	60 grains.	288 grains.
Acidi tannici.	Tannin 60 grains.	60 "	240 "
Aloes.	Powd. purif. aloes 60 grains.	60 "	240 "
Asafœtidæ.	Tinct. asafetida 1 fluidounce; evaporate spontaneously.	60 "	260 "
Belladonnæ.	Alcoh. extract belladonna 6 grains; water sufficient.	60 "	294 "
Morphiæ.	Morphine sulphate 6 grains.	60 "	294 "
Opii.	Extract opium 12 grains; water sufficient.	60 "	288 "
Plumbi.	Lead acetate 36 grains.	60 "	264 "
Plumbi et opii.	Lead acetate 36 grains; extract opium 6 grains; water sufficient.	60 "	260 "

Urethral suppositories are made in precisely the same manner as those intended for use in the rectum or vagina, the chief difference being in the shape, which should be cylindrical and slender, and in the greater stiffness of the vehicle. J. L. Lemberger (1871) made use of the well-known candle-mould, modified merely by making the tubes much smaller; and others have forced the mixture of cacao butter, wax, and medicinal substances through a narrow tube, and cut the cylinders thus obtained into pieces of a suitable length.

SUPPOSITORIA ACIDI CARBOLICI CUM SAPONE, *Br.*—CARBOLIC ACID SUPPOSITORIES.*Suppositoires d'acide phénique, Fr. ; Carbolsäure-Stuhlzüpfchen, G.*

Preparation.—Take of Carbolic Acid 12 grains; Curd Soap, in powder, 180 grains; Glycerin of Starch 40 grains or a sufficiency. Mix the ingredients so as to form a paste of suitable consistence. Divide the mass into twelve equal parts, each of which is to be made into a conical or other convenient form for a suppository. Each suppository contains 1 grain of carbolic acid.—*Br.*

Medical Uses.—This suppository is disinfectant and stimulant, and may be used in chronic *dysentery*, *hæmorrhoids*, *cancer*, and other diseases of the *rectum* attended with mucous, purulent, or bloody secretions or with fetor.

SUPPOSITORIA ACIDI TANNICI, *Br.*—TANNIC ACID SUPPOSITORIES.*Suppositoires de tannin, Fr. ; Tannin-Stuhlzüpfchen, G.*

Preparation.—Take of Tannic Acid 36 grains; Oil of Theobroma 144 grains. Rub the tannic acid with 44 grains of the oil of theobroma in a slightly warmed mortar, and add them to the remainder of the oil of theobroma previously melted at a low temperature; mix thoroughly, and pour the mixture while it is fluid into suitable moulds of the capacity of 15 grains; or, the fluid mixture may be allowed to cool, and then be divided into twelve equal parts, each of which shall be made into a conical or other convenient form for a suppository.—*Br.*

SUPPOSITORIA ACIDI TANNICI CUM SAPONE. Take of tannic acid 36 grains; glycerin of starch 30 grains; curd soap, in powder, 100 grains; starch, in powder, a sufficiency. Mix the tannic acid with the glycerin of starch and soap, and add sufficient starch to form a paste of suitable consistence. Divide the mass into twelve equal parts, each of which is to be made into a conical or other convenient form for a suppository.—*Br.*

Medical Uses.—Tannic acid suppositories are chiefly used to allay rectal or vaginal irritation, diminish local discharges, and constrict the flabby mucous membrane of these parts.

SUPPOSITORIA HYDRARGYRI, *Br.*—MERCURIAL SUPPOSITORIES.*Suppositoires mercuriels, Fr. ; Mercurial-Stuhlzüpfchen, G. .*

Preparation.—Take of Ointment of Mercury 60 grains; Oil of Theobroma 120 grains. Melt the oil of theobroma with sufficient heat, then add the ointment of mercury, and having mixed them thoroughly, without applying more heat, immediately pour the mixture, before it has congealed, into suitable moulds of the capacity of 15 grains; or, the fluid mixture may be allowed to cool, and then be divided into twelve equal parts, each of which shall be made into a conical or other convenient form for a suppository.—*Br.*

Medical Uses.—These suppositories appear to have been contrived for the purpose of affecting the system with mercury when for any reason it cannot be administered by the mouth.

SUPPOSITORIA MORPHINÆ, *Br.*—MORPHINE SUPPOSITORIES.*Suppositoires morphinés, Fr. ; Morphin-Stuhlzüpfchen, G.*

Preparation.—Take of Hydrochlorate of Morphine 6 grains; Oil of Theobroma 174 grains. Rub the hydrochlorate of morphine with 24 grains of the oil of theobroma in a slightly warmed mortar and add this to the remainder of the oil previously melted at a low temperature; mix the whole thoroughly, and pour the mixture while it is fluid into suitable moulds of the capacity of 15 grains; or, the fluid mixture may be allowed to cool, and then be divided into twelve equal parts, each of which shall be made into a conical or other convenient form for a suppository, which will contain $\frac{1}{2}$ grain of hydrochlorate of morphine.—*Br.*

SUPPOSITORIA MORPHINÆ CUM SAPONE. Take of hydrochlorate of morphine 6 grains; glycerin of starch 30 grains; curd soap, in powder, 100 grains; starch, in powder, a sufficiency. Mix the hydrochlorate of morphine with the glycerin of starch and soap, and add sufficient starch to form a paste of suitable consistence. Divide the mass into twelve

equal parts, each of which is to be made into a conical or other convenient form for a suppository.—*Br.*

Medical Uses.—Each of these suppositories contains half a grain of hydrochlorate of morphia, which is quite too large a dose for ordinary use.

SUPPOSITORIA PLUMBI COMPOSITA, *Br.*—COMPOUND LEAD SUPPOSITORIES.

Suppositoires de plomb opiacés, Fr.; *Stuhlzäpfchen von Opium und Bleizucker*, G.

Preparation.—Take of Acetate of Lead 36 grains; Opium, in powder, 12 grains; Oil of Theobroma 132 grains. Rub the acetate of lead and opium with 42 grains of the oil of theobroma in a slightly warmed mortar, and add them to the remainder of the oil previously melted at a low temperature; mix the whole thoroughly and pour the mixture while it is fluid into suitable moulds of the capacity of 15 grains; or, the fluid mixture may be allowed to cool, and then be divided into twelve equal parts, each of which shall be made into a conical or other convenient form for a suppository.—*Br.*

Medical Uses.—The combined astringent, soporific, and anodyne qualities of these suppositories render them appropriate in many affections of the *rectum*, *vagina*, and *uterus* attended with altered secretion and pain, such as *leucorrhœa*, *diarrhœa*, *dysentery*, *cancer*, etc.

SYMPHYTUM.—COMFREY-ROOT.

Radix symphyti, *Radix consolide majoris*. — *Consoude*, Fr.; *Schwarzwurzw*, *Beinwurz*, G.

The root of *Symphytum officinale*, *Linné*.

Nat. Ord.—Boraginaceæ.

Origin.—Comfrey is a European perennial growing on the banks of streams and in meadows, and now found in similar places in the United States, where it has escaped from gardens. It is a coarse-looking plant, with a bristly stem 20 to 40 inches (.5–1 M.) in height, and with lance-ovate or lanceolate alternate and rough leaves, which are narrowed into a winged petiole. The flowers are in racemose cymes, have a five-toothed calyx and a tubular bell-shaped yellowish-white or purplish corolla, with spreading teeth and linear scales closing the throat, and produce four smooth, glossy, brown-black akenes. The flowers appear in June. The root is collected in autumn or early in spring, and yields about 20 per cent. of air-dry drug.

Description.—Comfrey-root is fleshy, 6 or 8 inches (15–20 C.) long, about an inch (25 M.) thick above, several-headed, tapering, and with few branches. After drying it is deeply wrinkled longitudinally, often bent, of a purplish-black color externally, and breaks readily with an even somewhat waxy fracture, or in damp weather is rather tough. The bark is about one-eighth the diameter of the root, and has a thick black corky layer, the inner bark being whitish. The medullium consists of broad medullary rays and narrow wood-wedges, and is of a whitish color, or when old brownish. Comfrey-root is inodorous and has a mucilaginous, sweetish, and faintly astringent taste.

Constituents.—The most important principle contained in comfrey-root appears to be the large quantity of *mucilage*. The root contains also sugar, a little tannin, and a few starch-granules, but acquires with iodine only a brown, not a blue, color. Plisson (1829) isolated from the root a small quantity of *asparagin*.

Medical Uses.—Comfrey-root is both demulcent and astringent, and was esteemed in ancient times for hastening the cure of bruises and the cicatrization of wounds: hence its name, *consolida*. A popular method in France of treating *fissures of the nipple* is to apply a hollow section of the fresh root over the sore organ. A decoction of it is prescribed in *hæmoptysis*, *hæmaturia*, *metrorrhagia*, *diarrhœa*, and *dysentery*. It is made with from 2 to 4 drachms in a pint of water (Gm. 8–16 in Gm. 500).

SYRUPI.—SYRUPS.

Sirops, Fr.; *Syrups*, G.

Syrups are concentrated solutions of sugar in water or in aqueous or very slightly alcoholic solutions of medicinal substances. In a few instances vinegar or dilute acetic acid is the solvent, and in Europe certain syrups are made with wine. Syrup made of sugar and water is called *simple syrup*; all others are distinguished as *medicated syrups*, and

these may be again classified into *simple* and *compound medicated syrups*, in accordance with the number of drugs represented by them.

Preparation.—In preparing syrups only the best refined sugar should be employed, which is free from impurities, and when dissolved in water is less prone to fermentation than partially-refined sugar. The pharmacopœias direct most of the syrups to be prepared with the aid of heat. The necessary quantity of sugar is mixed with the liquid, a moderate heat is applied to the mixture, and this is frequently stirred until the sugar is dissolved, when the heat is raised to the boiling-point, and the syrup is strained for the purpose of removing dust and other accidental impurities that may have been contained in the sugar, and albumen, which is coagulated by heat from some aqueous infusions of drugs. After straining, the U. S. Pharmacopœia directs the weight of simple syrup to be adjusted by passing a sufficient quantity of water through the strainer. In following these directions literally the syrup may become too much diluted through the use of a large-sized strainer, which, with the vessel in which the syrup was made, would retain considerable of the latter; the strainer should therefore be as small as possible, and water equal to only about one-half the weight to be made up should be used until the vessel and strainer have been thoroughly rinsed with it, when more water may be added. All undue dilution may be avoided by ascertaining the weight of the syrup previous to straining, and afterward rinsing the vessel and strainer only with sufficient water to make up the difference. The German Pharmacopœia very properly directs the adjusting of the weight to be done *before* the syrup is strained or filtered, and the U. S. P. has adopted the same precaution for all syrups made without heat.

Most syrups of the U. S. P. are now directed to be made by dissolving the sugar in the proper liquid without heat, with the view of avoiding the evaporation of volatile ingredients and the inverting influence of hot acid liquids upon the cane-sugar. L. Orynski (1871) proposed to extend this process to all syrups, and the method has been found by R. Hunstock (1875) and others not only much easier and more economical than the official process, but likewise to yield syrups which, as a rule, are less liable to ferment. This latter quality may probably be directly referred to the avoidance of heat, since the continued application of heat is known to produce changes in the sugar resulting in the formation of glucose. Simple syrup, made by dissolving the sugar at the boiling-point very soon after it has been prepared, reduces alkaline solutions of copper, showing the formation of grape-sugar, while simple syrup made from the same sugar, but without heat, forms grape-sugar more slowly. This so-called *cold process* for preparing syrups therefore deserves the attention of pharmacists. The menstruum is in all cases prepared as directed by the Pharmacopœia; the requisite quantity of sugar is then introduced into a conical percolator, the lower orifice of which is closed with a cork, and into the neck of which a piece of loose sponge or cotton, previously moistened, is introduced. The liquid is now poured into the percolator, and the whole set aside in a moderate temperature until the sugar has been partially dissolved and melted down to about one-half of its original volume, when the cork may be removed and the syrup allowed to drop; it should be perfectly clear and transparent, or the turbid portion returned to the percolator. If the sugar is not all dissolved when the liquid has passed, this is to be again percolated through the sugar. With proper management a repetition of the process will be rarely required. Syrups prepared in this manner with perfect emulsions will be opaque. If made with aqueous infusions of drugs, such syrups will contain the soluble albuminous principles, and probably not be quite as unchangeable as those prepared with the aid of heat; but if the drug had been exhausted by an alcoholic liquid, as directed by the U. S. P. for most of the syrups to which these remarks apply, albumen is not present.

If heat is employed, as directed by the pharmacopœias for most syrups, the loss occasioned by evaporation should be rectified by the addition of water. This is easily accomplished by taking the weight of the vessel with its contents before and after boiling, and adding enough water to compensate for the loss occasioned by heating. If clarification by means of white of egg should be necessary, this is best added to the cold aqueous liquid. Paper-pulp may be used for the same purpose.

The preparation of the aqueous liquid used for dissolving the sugar is of great importance. The pharmacopœias have very properly discarded the exhaustion of the crude drugs by boiling them with water, since thereby starch and other principles are dissolved which easily undergo chemical changes and interfere with the stability of the syrups. The United States Pharmacopœia has, for the same reasons, abandoned the employment of hot water in exhausting the drugs. The most stable medicated syrups are obtained if the drug is treated with cold water, diluted alcohol, or alcohol, as the case may be,

either by maceration or preferably by percolation. For this part of the process all the precautions are required which have been pointed out in another place (see pp. 605-609). The percolate is concentrated, and, if necessary, deprived of alcohol, particular care being required to prevent the evaporation of volatile principles and the change of others by the influence of an elevated temperature. Filtration of the concentrated liquid is usually required, and it should be borne in mind that it is much easier to pass a concentrated aqueous infusion of a drug or an aqueous solution of an alcoholic extract through a filter than to perform the same operation with a syrup.

The proper proportion of sugar to menstruum ensures the stability of the syrup. Should the sugar be deficient in quantity, it could not efficiently protect the other organic principles contained in the syrup, and it would be liable to ferment. On the other hand, if too much sugar be employed, the excess would crystallize after cooling, and dispose an additional quantity to separate in a like manner, thus leaving the syrup weaker in sugar than it should be, and subject to similar alterations as if an insufficient quantity of sugar had been used. The proper proportion of sugar is a little less than twice the weight of water, or 35 parts of water to 65 parts of sugar, as directed by the United States Pharmacopœia for simple syrup. For colder climates a little more water may be employed; the German Pharmacopœia directs 40 parts of water to 60 parts of sugar. If the liquid contains already much organic matter in solution or if it is partially alcoholic, a correspondingly smaller amount of sugar will be required.

A process was recommended by Isaac Davis (1878) in which the principle adopted by Orynski is still further extended. Mr. Davis proposed to make the medicated syrups by percolating the powdered drugs with simple syrup prepared by the cold process.

(For remarks on the preparation of *fruit-syrups* see SYRUPUS MORI and SYR. RUBI IDÆI.)

Preservation.—The finished syrups should be introduced into dry bottles, so as to avoid diluting them with water; if bottled while warm, condensation of aqueous vapors in the neck of the bottle will cause dilution of the upper stratum and disposition to fermentation, unless the syrup be thoroughly mixed after cooling. Properly prepared, syrups may generally be kept unaltered, even in partially filled bottles, at the ordinary temperatures, but it is best to keep them in a place where the temperature will not vary materially between about 15° and 20° C. (59° and 68° F.). The addition of small quantities of spirit of ether, Hoffmann's anodyne, chlorate of potassium, and more recently of salicylic acid, has been recommended for the purpose of preserving syrups; but all these additions are more or less objectionable, and generally unnecessary if, in the exhaustion of the drug, heat is avoided.

Restoration.—When fermentation sets in, the carbonic acid gas disengaged causes the syrups to assume a frothy appearance, and a vinous odor is noticed. As soon as these signs make their appearance the syrup should be heated to boiling, strained, and afterward properly preserved. The medicinally active principles will rarely have undergone any alteration, except in the case of syrups of acacia and of almond; but syrups which owe their virtues wholly or in part to volatile principles, or in which fermentation has proceeded beyond the incipient stage, cannot be thus restored without being impaired in their properties. For syrups prone to fermentation the employment of glycerin in place of a corresponding quantity of liquid and sugar has been recommended.

Properties.—Syrups should be perfectly transparent, with the few exceptions noted below. When heated to boiling they have the density indicated by 30° B. = 1.26 (*F. Cod.*). At 15° C. (59° F.) the density of simple syrup is 1.310 (*U. S.*), 1.32 (*F. Cod.*), 1.330 (*Br.*), and most of the medicated syrups have about the same specific gravity. The employment of carbonate of magnesium in the preparation of syrups renders them unfit for being dispensed with salts of morphine, strychnine, or other poisonous alkaloids. (See *AQUÆ MEDICATÆ*, p. 232.)

SYRUPUS, *U. S.*, *Br.*—SYRUP.

Syrupus simplex, P. G.; *Syrupus sacchari*, F. Cod.; *Syr. albus*.—*Simple syrup*, E.; *Sirap de sucre*, *Sirap simple*, Fr.; *Weisser Syrup*, G.

Preparation.—Sugar, in coarse powder, 65 parts (4 lbs. 1 oz. av.); Distilled Water a sufficient quantity; to make 100 parts (6½ lbs. av.). Dissolve the sugar, with the aid of heat, in 35 parts of distilled water, raise the temperature to the boiling-point, and strain the solution while hot. Then incorporate with the solution enough distilled water, added through the strainer, to make the syrup weigh 100 parts (6½ lbs. av. or 7¾ fluid-

ounces).—*U. S.* To make 1 gallon of simple syrup use 7 lbs. $1\frac{3}{4}$ oz. av. of sugar and 3 lbs. $13\frac{1}{4}$ oz. av. or 58 $\frac{3}{4}$ fluidounces of distilled water.

The Pharmacopœia states that syrup thus prepared has the specific gravity 1.310, which is too low. The syrup of the *U. S. P.* 1870 contained 65.455 per cent. of sugar, and its specific gravity was given as being 1.317, which figure closely corresponds with the results of Balling, Brix, Gerlach, and others. The British Pharmacopœia orders 5 pounds of sugar and sufficient distilled water to make $7\frac{1}{2}$ pounds of syrup, which contains 66.667 per cent. of sugar and is stated to have the density of 1.330. The French Codex orders 64.286 per cent. of sugar, and gives the density 1.32.

Pharmaceutical Uses.—Simple syrup is used in the preparation of certain confections, mixtures, and syrups, and as an excipient in several pill masses.

Medical Uses.—Syrup—or “simple syrup,” as it was formerly and more definitely called—is a most important member of the pharmacopœia, not only because it preserves medicines associated with it from undergoing change, but because it renders them more acceptable to the palate and mitigates their action upon the alimentary canal. It should, however, not be used in large doses nor for a long time together, lest it impair the appetite and digestion. It may be employed as a protective for superficial burns and abrasions.

SYRUPUS ACACIÆ, *U. S.*—SYRUP OF GUM-ARABIC.

Syrupus gummosus.—*Sirop de gomme*, Fr.; *Gummisyrup*, G.

Preparation.—Mucilage of Acacia 25 parts ($\frac{1}{4}$ oz.); Syrup 75 parts ($\frac{3}{4}$ oz.); to make 100 parts (1 oz.). Mix them. This syrup should be freshly made when required for use.—*U. S.*

This is the formula of the *P. G.* 1872, from the revised edition of which this syrup has been dismissed. While it is desirable to prepare this syrup extemporaneously, it should be remembered that mucilage of acacia, which is not preserved by sugar, is readily altered on exposure, and likely to induce decomposition when used in mixtures; it is therefore important that the mucilage be of good quality.

The formula of the French Codex is similar to the following, which is the formula of the *U. S. P.* 1870: Dissolve 2 troyounces of gum-arabic in 8 fluidounces of water, without heat; then, having added 14 troyounces of sugar, dissolve it with a gentle heat and strain.

Medical Uses.—Syrup of gum-arabic is chiefly used to aid in suspending more active substances in mixtures and impart an agreeable flavor to them, as a demulcent in catarrhal affections of the throat and larynx, and as a palatable addition to drinking water.

SYRUPUS ACIDI CITRICI, *U. S.*—SYRUP OF CITRIC ACID.

Sirop d'acide citrique, *Sirop de limon*, Fr.; *Citronensäuresyrup*, G.

Preparation.—Citric Acid 8 parts ($\frac{1}{2}$ oz. av.); Water 8 parts ($\frac{1}{2}$ oz. av.); Spirit of lemon 4 parts ($\frac{1}{4}$ oz. av.); Syrup 980 parts (61 $\frac{1}{4}$ oz. av. or 45 fluidounces); to make 1000 parts (62 $\frac{1}{2}$ oz. av. or 46 fluidounces). Mix the spirit of lemon with the syrup contained in a bottle; then add gradually the citric acid dissolved in the water, shaking the bottle after each addition until the whole is thoroughly mixed.—*U. S.*

This syrup resembles lemon syrup. Its flavor has been improved by the use of spirit in place of oil of lemon, formerly ordered.

Medical Uses.—This syrup is used as a flavoring ingredient chiefly. It is intended as a substitute for lemon syrup made from the recent fruit, for which, however, it is by no means an equivalent.

SYRUPUS ACIDI HYDRIODICI, *U. S.*—SYRUP OF HYDRIODIC ACID.

Sirop d'acide iodhydrique, Fr.; *Jodwasserstoffsyrup*, G.

A syrupy liquid, containing 10 per cent. of absolute hydriodic acid, HI. Molecular weight 127.6. / 80

Preparation.—Iodine 10 parts (140 grains); Alcohol 80 parts (1120 grains or 3 fluidounces); Syrup 150 parts (2100 grains or 3 $\frac{1}{2}$ fluidounces); Sugar 500 parts (1 lb. av.); Spirit of Orange 5 parts (70 grains or 90 minims); Distilled Water in sufficient quantity; to make 1000 parts (2 lbs. av. or 24 $\frac{1}{4}$ fluidounces). Dissolve the iodine in the alcohol, with a very gentle heat, in a loosely-stoppered flask, avoiding loss of iodine from

vaporization. Add the solution to the syrup previously mixed with 150 parts (60 oz. av. or 5½ fluidounces) of distilled water, and pass through the mixture a current of hydrosulphuric acid gas until it acquires a pure yellowish color and ceases to turn brown on shaking. Filter the liquid through white filtering-paper, returning the first portions until it runs off clear; wash the filter with a little distilled water, and evaporate the filtrate and washings, in a tared porcelain capsule on a water-bath, at a temperature not exceeding 55° C. (131° F.), constantly stirring until all odor of hydrosulphuric acid has disappeared. Then set the capsule aside, well covered, and allow the contents to cool. When cold add the spirit of orange, the sugar, and enough distilled water to make the whole weigh 1000 parts (2 lbs. av.). When the sugar has been dissolved by stirring, strain the syrup through a pellet of cotton placed in the neck of the funnel, which is to be kept covered, and transfer the filtered syrup to small vials, which should be completely filled, securely corked, and kept in a cool and dark place.—*U. S.*

The reactions occurring in the preparation of this acid have been described elsewhere. On adding the alcoholic solution of iodine to the syrup the iodine will separate as a fine powder, which will rapidly settle in the liquid: therefore, to avoid loss, the precaution pointed out on page 59, to add the iodine gradually to the liquid in which the conversion into hydriodic acid takes place, should also be observed in this case.

Properties.—This syrup is described as “a transparent, colorless, or not more than pale straw-colored liquid, odorless, having a sweet and acidulous taste and an acid reaction. Sp. gr. 1.300. If disulphide of carbon be poured into a small portion of the syrup, a little chlorine-water then added, and the whole agitated, the disulphide will separate with a violet color.”—*U. S.* Sugar will in a measure, but not completely, prevent the oxidation of the acid and the liberation of iodine; hence a pale straw-color of the otherwise colorless syrup is permitted.

Tests.—“Gelatinized starch added to the syrup should not impart to it more than a faint bluish tint (absence of more than traces of free iodine). Test solution of chloride of barium added to a portion of the syrup, should produce no precipitate (absence of sulphuric acid). Test solution of nitrate of silver produces a precipitate which is nearly insoluble in water of ammonia (absence of hydrochloric acid). To neutralize 25.5 Cem. of syrup of hydriodic acid should require 20 Cem. of the volumetric solution of soda.”—*U. S.* The volumetric test is useful only after the absence of other organic as well as inorganic acids has been proven. The test designed to show the absence of hydrochloric acid should be supplemented by the direction that the ammoniacal filtrate from the silver precipitate, on being acidulated, should not be rendered more than faintly turbid.

Medical Uses.—As was mentioned under HYDRIODIC ACID, the virtues of that compound are chiefly of a local stimulant and caustic nature: the evidence of its utility as an internal medicine are, in our judgment, too slender to entitle it to an official position in the comparatively stable form of a syrup. The *dose* of the syrup is stated at a fluid-drachm (Gm. 4), largely diluted. It has been given in chronic bronchitis, chronic malarial poisoning, etc. It appears to be a superfluous addition to the Pharmacopœia.

SYRUPUS ALLII, *U. S.*—SYRUP OF GARLIC.

Sirop d'ail, Fr.; *Knoblauchsyrup*, G.

Preparation.—Fresh Garlic, sliced and bruised, 15 parts (3 oz. av.); Sugar, in coarse powder, 60 parts (12 oz. av.); Diluted Acetic Acid 40 parts (8 oz. av. or 7½ fluidounces); to make 100 parts (20 oz. av. or about 14 fluidounces). Macerate the garlic with 25 parts (5 oz. av. or 4¾ fluidounces) of the diluted acetic acid in a glass vessel for four days, and express the liquid. Then mix the residue with the remainder of the acid, and again express until enough additional liquid has been obtained to make the whole, when filtered, weigh 40 parts (8 oz. av.). Lastly, pour the filtered liquid upon the sugar contained in a suitable bottle, and agitate until it is dissolved. Keep the syrup in well-stopped, filled bottles in a cool place.—*U. S.*

Thus prepared, syrup of garlic is somewhat opalescent and has the odor of the drug in a marked degree.

Medical Uses.—This is the form in which garlic is generally employed internally. It is very commonly used in subacute and chronic *catarrhs* of the respiratory passages in children and infants, and particularly in the decline of *whooping cough*. The *dose* is about a teaspoonful (Gm. 4).

SYRUPUS ALTHÆÆ, U. S., P. G.—SYRUP OF ALTHÆA.

Syrup of marshmallow, E.; *Sirop de guimauve*, Fr.; *Eibischsaft*, G.

Preparation.—Althæa, cut in small pieces, 4 parts (1 oz. av.); Sugar, in coarse powder, 60 parts (15 oz. av.); Water a sufficient quantity; to make 100 parts (20 oz. av. or about 18 fluidounces). Having washed the althæa with cold water, pour upon it 60 parts (15 oz. av. or 14½ fluidounces) of cold water, and macerate for 1 hour, stirring frequently; then strain through flannel without expressing. To 40 parts (10 oz. av. or 9 fluidounces) of the strained liquid add the sugar, and dissolve it by agitation without heat. This syrup should be freshly made when required for use.—*U. S.*

This is the formula of the P. G. 1872, with the marshmallow-root somewhat increased, but the sugar decreased in quantity; which changes will not render the syrup more permanent. Cold water must be used for maceration to avoid dissolving the starch, but the duration of maceration may very properly be prolonged for one or two hours, and by increasing the sugar the tendency to ferment will be lessened. The following formula yields a syrup less liable to these objections, and by doubling the quantity of marshmallow-root a syrup of the same mucilaginous strength as the above will be obtained: Macerate for 3 hours althæa 1 part, cold water 25 parts, and alcohol 1 part; strain without pressure, and in 20 parts of the liquid dissolve 30 parts of sugar.—*P. G.*

The syrup has a yellowish color and a slight agreeable odor.

Medical Uses.—This syrup, now for the first time officinal, is universally employed in France to sweeten ptisans used in sore throat and inflammations of the air-passages.

SYRUPUS AMYGDALÆ, U. S.—SYRUP OF ALMOND.

Syrupus amygdalarum, s. *Syr. emulsivus*, P. G.—*Sirop d'amande*, *Sirop d'orgeat*, Fr.; *Mandelsyrup*, G.

Preparation.—Sweet Almond 10 parts (2½ oz. av.); Bitter Almond 3 parts (¾ oz. av.); Sugar, in coarse powder, 50 parts (12½ oz. av.); Orange-Flower Water 5 parts (1¼ oz. av. or 9½ fluidrachms); Water a sufficient quantity; to make 100 parts (25 oz. av. or about 18 fluidounces). Having blanched the almonds, rub them in a mortar to a very fine paste, adding during the trituration 3 parts (6 fluidrachms) of water and 10 parts (2½ oz. av.) of sugar. Mix the paste thoroughly with the orange-flower water and 30 parts (7½ oz. av. or 7½ fluidounces) of water; strain with strong expression, and add enough water to the dregs to obtain, after renewed expression, 60 parts (15 oz. av. or nearly 13 fluidounces) of strained liquid. To this add the remainder of the sugar, dissolve it by agitation without heat, and strain through muslin. Keep the syrup in well-stopped, filled bottles in a cool place.—*U. S.*

This formula is modified after that of the French Codex, but endeavors to avoid heat by dissolving the sugar by agitation or percolation. The pharmacopœias direct for 100 parts of sugar 10 parts, *U. S.* (9 parts *F. Cod.*, and 5 parts, *P. G.*), of orange-flower water. The syrup is whitish and opaque, and in order to obtain it free from dark color the integuments of the seeds must be completely removed, for which purpose the almonds are for a few minutes steeped in warm water.

Medical Uses.—Almond or orgeat syrup is an agreeable addition to expectorant and diuretic mixtures, and is possibly a feeble sedative of mild forms of febrile and nervous disorder through the minute proportion of hydrocyanic acid it contains. It is much used, mixed with water, in irritation of the urinary passages.

SYRUPUS AURANTII, U. S., Br.—SYRUP OF ORANGE.

Syrupus aurantii corticis, P. G.—*Syrup of orange-peel*, E.; *Sirop d'écorce d'orange amère*, Fr.; *Pomeranzenschalensyrup*, G.

Preparation.—Sweet Orange-Peel, recently separated from the fresh fruit, deprived of the inner white layer, and cut into small pieces, 5 parts (2½ oz. av.); Alcohol 5 parts (2½ oz. av. or 3 fluidounces); Precipitated Phosphate of Calcium 1 part (½ oz. av.); Sugar 60 parts (30 oz. av.); Water a sufficient quantity; to make 100 parts (50 oz. av. or about 2½ pints). Macerate the orange-peel with the alcohol for 7 days; then express the liquid. Rub this with the precipitated phosphate of calcium and 30 parts (15 oz. av. or 14½ fluidounces) of water, gradually added; filter the mixture, and pass enough water through the filter to make the filtrate weigh 40 parts (20 oz. av. or 19 fluidounces). Lastly, add the sugar, dissolve it by agitation without heat, and strain.—*U. S.*

Tincture of orange-peel 1 fluidounce; syrup 7 fluidounces. Mix.—*Br.*

The corresponding syrups of the French and German Pharmacopœias are made with bitter orange-peel, which, according to the former authority, is exhausted with alcohol of 6 per cent., and, according to the latter, with white wine; in the tincture thus obtained the sugar is dissolved. The U. S. P. makes the syrup from fresh sweet orange-peel, the volatile oil of which, together with some coloring matter, is dissolved by maceration with alcohol and expression; this tincture is treated in a manner similar to the volatile oils in the preparation of medicated waters (see page 232). Syrup of orange has a yellowish color and an agreeable odor and taste.

Medical Uses.—This syrup is merely an agreeable flavoring ingredient of medicinal mixtures. Its more decided taste, as compared with that of lemon and other simple official syrups, constitutes its special advantage.

SYRUPUS AURANTII FLORUM, U. S., P. G.—SYRUP OF ORANGE-FLOWERS.

Syrupus aurantii floris, *Br.*—*Sirap de fleur d'orange*, *Fr.*; *Pomeranzenblüthensyrup*, *G.*

Preparation.—Orange-Flower Water 35 parts (14 oz. av. or 13½ fluidounces); Sugar, in coarse powder, 65 parts (26 oz. av.); to make 100 parts (2½ lbs. av. or 29 fluidounces). Dissolve the sugar in the orange-flower water by agitation, without heat.—*U. S.*

With the exception of a decrease of the sugar to 64.29 parts, the formula of the French Codex is identical with the above. The *Br. P.* directs the orange-flower water to be diluted with twice its weight (equal weight, *P. G.*) of water. The German Pharmacopœia permits this syrup to be dispensed in the place of *Syrupus capillorum Veneris*, or syrup of maidenhair (see p. 122).

Medical Uses.—Syrup of orange-flowers is a pleasant flavoring agent, with a possibility of exercising a slight sedative influence upon morbidly sensitive persons, since one-third of it consists of orange-flower water.

SYRUPUS CALCII LACTOPHOSPHATIS, U. S.—SYRUP OF LACTOPHOSPHATE OF CALCIUM.

Sirap de lactophosphate (phospho-lactate) de chaux, *Fr.*; *Calciumphospholactat-syrup*, *G.*

Preparation.—Precipitated Phosphate of Calcium 22 parts (440 grains = 1 oz. av. and 2½ grains); Lactic Acid 33 parts (660 grains or 9 fluidrachms and 34 minims); Orange-Flower Water 80 parts (1600 grains or 3½ fluidounces); Sugar, in coarse powder, 600 parts (12,000 grains or 27½ oz. av.); Hydrochloric Acid, Water of Ammonia, Water, each a sufficient quantity; to make 1000 parts (20,000 grains = 2 lbs. 13¾ oz. av. or about 33 fluidounces). To the precipitated phosphate of calcium, mixed with 300 parts (13¼ oz. av. or 13½ fluidounces) of cold water, add enough hydrochloric acid to dissolve it. Filter the solution, dilute it with 1200 parts (55 oz. av. or 52¾ fluidounces) of cold water, and then add water of ammonia until it is slightly in excess. Transfer the mixture at once to a fine, wetted muslin strainer. As soon as the liquid has run off return the magma to the vessel, mix it quickly with 1200 parts (55 oz. av.) of cold water, and again transfer it to the strainer. When it has drained mix the magma at once with the lactic acid, and stir until it is dissolved. Then add the orange-flower water and enough water to make the solution weigh about 350 parts (7000 grains = 1 lb. av.); filter, and pass enough water through the filter to make the filtrate weigh 400 parts (8000 grains = 18¼ oz. av. and 16 grains). Lastly, add to this the sugar, dissolve it by agitation without heat, and strain.—*U. S.*

This formula is a modification of the one proposed by Dr. Neergaard, by whom the syrup was first made in 1871. The first portion of the process has for its object the preparation of freshly-precipitated calcium phosphate, which is readily soluble in lactic acid. In this operation, as well as in dissolving the sugar, heat must be avoided, else a precipitate will be produced; the addition of a little lactic acid to the syrup will render the lime compound permanently soluble, provided the syrup be kept in a cool place.

The formula of the French Codex (1884) has been given on p. 355. Replacing the lactic acid by a sufficient quantity of hydrochloric acid, *sirap de chlorhydrophosphate de chaux* is obtained. *Sirap de phosphate acide de chaux* is made in the same manner, using sufficient phosphoric acid for dissolving the lime salt.

Medical Uses.—Not the least evidence exists that this preparation is endowed with medicinal virtues. It is intended especially to act as a reconstituent, but the proportion of lime contained in it is so minute that its action, of any sort, must be quite illusory. Moreover, as the greater part of the compound consists of sugar, it tends to produce or to prolong the gastric fermentation that exists in cases which require the use of true reconstituents. The *dose* of this preparation is at the option of the prescriber, from a teaspoonful to a wine-glassful, diluted.

SYRUPUS CALCIS, U. S.—SYRUP OF LIME.

Liquor calcis saccharatus, Br. ; *Syrupus calcaria*.—*Saccharated solution of lime*, E. ; *Siròp de chaux*, Fr. ; *Kalksyrup*, G.

Preparation.—Lime 5 parts (1 oz. av.) ; Sugar, in coarse powder, 30 parts (6 oz. av.) ; Water a sufficient quantity ; to make 100 parts (20 oz. av. or about a pint). Triturate the lime and sugar thoroughly in a mortar ; then add the mixture to 50 parts of boiling water contained in a bright copper or tinned-iron vessel, and boil the mixture for five minutes, constantly stirring. Dilute it with an equal volume of water and filter through white paper. Finally, evaporate the syrup to 100 parts (20 oz. av.).—U. S.

Take of slaked lime 1 ounce ; refined sugar, in powder, 2 ounces ; distilled water 1 pint. Mix the lime and the sugar by trituration in a mortar. Transfer the mixture to a bottle containing the water, and, having closed this with a cork, shake it occasionally for a few hours. Finally, separate the clear solution with a siphon, avoiding unnecessary exposure to the air, and keep it in a well-stoppered bottle.—Br.

Water containing sugar dissolves a larger quantity of lime than pure water. Peligot ascertained the solubility for 100 parts of sugar in solutions of 40 per cent. to be 26.57 parts ; of 20 per cent., only 23.15 parts ; and in solutions of 5 per cent., only 18.06 parts of lime. According to these observations, the first formula must yield a preparation stronger in lime than that of the Br. P. Cane-sugar boiled with a strong solution of an alkali is gradually turned brown, while weak alkaline liquids have very little effect upon it (Hochstetter, 1843) ; and a concentrated solution of cane-sugar may be boiled with lime for a long time before decomposition commences (Dubrunfaut, Soubeiran).

This preparation is a thin, syrupy, colorless liquid, and has a bitter alkaline and somewhat sweet taste and an alkaline reaction. On exposure to air it absorbs carbonic acid gas, and must therefore be preserved in well-stopped bottles. Prepared according to the Br. P., it has the specific gravity 1.052, and 460.2 grains (1 fluidounce) require for neutralization 254 grain-measures of volumetric solution of oxalic acid, which corresponds to 7.11 grains of lime in 1 fluidounce (Imperial), or 1.546 per cent. of CaO.

Medical Uses.—The benefits which the lime in this preparation is fitted to produce are more or less prevented by the associated sugar. For all useful purposes pure lime-water is to be preferred. In Germany it has been recommended in poisoning by certain acids, as carbolic and oxalic acids. Its *dose* is not fixed, but may be stated at a teaspoonful or more, diluted.

SYRUPUS CHLORAL, Br.—SYRUP OF CHLORAL.

Siròp de chloral, Fr. ; *Chloralsyrup*, G.

Preparation.—Take of Hydrate of Chloral 80 grains ; Distilled Water $1\frac{1}{2}$ fluidrachms ; Simple Syrup a sufficiency. Dissolve the hydrate of chloral in the water, and add the syrup until the mixed product measures a fluidounce.—Br.

The syrup of the F. Cod. contains only 5 per cent. of chloral hydrate, and is flavored with spirit of peppermint.

Medical Uses.—This preparation is a convenient vehicle for the administration of chloral in definite doses. Each fluidrachm of it contains 10 grains of hydrate of chloral. The ordinary *dose* is from $\frac{1}{2}$ to 1 fluidrachm (Gm. 2-4).

SYRUPUS FERRI BROMIDI, U. S.—SYRUP OF BROMIDE OF IRON.

Syrupus ferri bromati.—*Siròp de bromure de fer*, Fr. ; *Eisenbromürsyrup*, G.

A syrupy liquid, containing 10 per cent. of ferrous bromide, FeBr₂. Molecular weight 215.5.

Preparation.—Iron, in the form of fine wire and cut into small pieces, 30 parts (1½ oz. av.) ; Bromine 75 parts (3 oz. av.) ; Sugar, in coarse powder, 600 parts (24 oz.

av.); Distilled Water a sufficient quantity; to make 1000 parts (40 oz. av. or about 28 fluidounces). Introduce the iron into a flask of thin glass of suitable capacity; add to it 200 parts (8 oz. av. or 7 fluidounces and $5\frac{1}{2}$ fluidrachms) of distilled water, and afterward the bromine. Shake the mixture occasionally until the reaction ceases and the solution has acquired a green color and has lost the odor of bromine. Place the sugar in a porcelain capsule, and filter the solution of bromide of iron into the sugar. Rinse the flask and iron wire with 90 parts ($3\frac{3}{4}$ oz. or $27\frac{1}{2}$ fluidrachms) of distilled water, and pass the washings through the filter into the sugar. Stir the mixture with a porcelain or wooden spatula, heat it to the boiling-point on a sand-bath, and, having strained the syrup through linen into a tared bottle, add enough distilled water to make the product weigh 1000 parts ($2\frac{1}{2}$ lbs. oz.). Lastly, shake the bottle, and transfer its contents to small vials, which should be completely filled, securely corked, and kept in a place accessible to daylight.—*U. S.*

The union of bromine and iron generates heat, which may rise to such a degree as to volatilize a portion of the bromine. Mr. W. S. Thompson, who published a formula for this syrup in 1870, advised to add the iron in small quantities to the bromine contained under water; this avoids annoyance by the irritating vapors of bromine, and toward the close of the reaction the iron may be added more freely. The reaction is known to be completed when the liquid is green and entirely free from the reddish tint and from the odor of bromine.

Properties.—Syrup of bromide of iron is a pale-green, transparent liquid, which is bleached on exposure to sunlight. It is inodorous, has a sweet and strongly ferruginous taste and a slightly acid (neutral, *U. S.*) reaction, shows to reagents the behavior of ferrous salts (see page 697), and the addition of a little chlorine-water liberates bromine, which has to solvents and to starch the behavior described on page 333. In contact with air it is slowly oxidized, and the yellow or brownish color disappears again on heating.

Tests.—"It should not deposit a sediment on keeping, and should not tinge gelatinized starch yellow (absence of free bromine). 10 Gm. of the syrup should require for complete precipitation not less than 1.57 Gm. of nitrate of silver (corresponding to 10 per cent. of ferrous bromide)." — *U. S.*

Medical Uses.—We have stated elsewhere (p. 673) the reasons which appear to render the bromide of iron an unnecessary, if not a dangerous, preparation. Its presumed medicinal effects may be more certainly secured by the administration of a salt of iron and one of bromine, alternately or conjointly. The quantities of this syrup representing the average doses of ferrous bromide would be from 5 to 20 drops (Gm. 0.06–1.30), but much larger doses have been prescribed, as fʒss to fʒj (Gm. 2–4).

SYRUPUS FERRI IODIDI, *U. S., Br.*—SYRUP OF IODIDE OF IRON.

Syrupus ferri iodati, P. G.; *Sirope d'iodure de fer*, Fr.; *Eisenjodirsyrup*, G.

A syrupy liquid, containing 10 per cent. of ferrous iodide, FeI_2 . Molecular weight 309.1.

Preparation.—Iron, in the form of fine wire and cut into small pieces, 25 parts (1 oz. av.); Iodine 82 parts (3 oz. av. and $122\frac{1}{4}$ grains); Sugar, in coarse powder, 600 parts (24 oz. av.); Distilled Water a sufficient quantity; to make 1000 parts (40 oz. av. or about 28 fluidounces). Introduce the iron into a flask of thin glass of suitable capacity; add to it 200 parts (8 oz. av. or 7 fluidounces and $5\frac{1}{2}$ fluidrachms) of distilled water, and afterward the iodine. Shake the mixture occasionally until the reaction ceases and the solution has acquired a green color and has lost the odor of iodine. Place the sugar in a porcelain capsule and filter the solution of iodide of iron into the sugar. Rinse the flask and iron wire with 90 parts ($3\frac{3}{4}$ fluidounces or $27\frac{1}{2}$ fluidrachms) of distilled water, and pass the washings through the filter into the sugar. Stir the mixture with a porcelain or wooden spatula, heat it to the boiling-point on a sand-bath, and, having strained the syrup through linen into a tared bottle, add enough distilled water to make the product weigh 1000 parts ($2\frac{1}{2}$ lbs. av.). Lastly, shake the bottle and transfer its contents to small vials, which should be completely filled, securely corked, and kept in a place accessible to daylight.—*U. S.*

On bringing iodine together with an excess of iron in the presence of water, ferrous iodide is formed and dissolves with a pale-green color. This compound has the formula FeI_2 , and contains very nearly 82 per cent. of iodine. The aqueous solution, which

should not be filtered until it has a pale-green color entirely free from any brown tint, is prone to change, but when protected by sugar, as proposed by Frederking (1839), and preserved with some precautions, it keeps unaltered. The details of the process given above are very similar to those of the German Pharmacopœia, both authorities directing the solution of ferrous iodide to be filtered upon the sugar, which is subsequently dissolved in the liquid by the aid of heat. Heretofore, the U. S. P., in common with the British Pharmacopœia, had adopted the plan of preparing a concentrated solution of ferrous iodide and filtering this into warm syrup, in which it sinks, owing to its greater density, and is thus perfectly protected against the oxidizing influence of the air. We prefer this manipulation to that at present recommended, and the process may be thus modified by dissolving the sugar in one-third its weight of water with the aid of heat, and in the mean time combining the iodine by adding it gradually to the iron kept under about two-thirds of the remaining water, the last portion being used for rinsing the flask and the filter. The strength of this syrup varies in the different pharmacopœias, that of the French Codex being much weaker than the others: 1 part of iodine (= 1.2 part of ferrous iodide) is represented by about 12.2 (*U. S.*), 21.5 (*Br.*), 24.4 (*P. G.*), and 244 (*F. Cod.*) parts of the syrup; or 1000 parts of the syrup contain 82 (*U. S.*), 46.5 (*Br.*), 41 (*P. G.*) and 4.10 (*F. Cod.*) parts of iodine.

Properties.—Syrup of iodide of iron is transparent, pale-green, nearly inodorous, and has a sweet, strongly ferruginous taste and a slightly acid (neutral, *U. S.*) reaction. It shows the behavior of solutions of ferrous salts (see page 697), and the addition of a little bromine-water liberates iodine, which has to solvents and to starch the behavior described on page 832. On exposure to the air the color of the syrup slowly changes to yellow and afterward to brown, the change of color proceeding from the exposed surface downward. Diffused daylight seems to somewhat accelerate the decomposition, but exposure to the direct sunlight entirely prevents the change, or, if it has taken place, restores the original color, and finally renders the syrup colorless. The effects of oxidation become manifest first by the production of ferric compound, and soon afterward by the liberation of iodine, recognized by the blue color produced with starch-paste; subsequently hydrate of iron containing variable quantities of iodine is precipitated, and after a short time this precipitate is not wholly redissolved again under the influence of sunlight, though the solution becomes colorless, perhaps from the formation of hydriodic acid. The application of heat has a similar effect. Syrups of the density of the above official syrups are not easily affected by exposure to the air, and we have known them to be kept in half-filled vials for months without apparent change. But if, from want of attention to the details of the process, the syrup should become colored from iodine, we prefer to restore it by exposure to sunlight, in preference to using a hyposulphite or other deoxidizing agents, which have been recommended for this purpose.

Should the iron used in preparing the solution of ferrous iodide be contaminated with other metals, these are likely to be dissolved. We have occasionally observed the syrup to contain a minute quantity of copper. On evaporating the syrup with due care to dryness, a yellowish-white powder is obtained, which is again soluble in water, yielding a slightly turbid solution (see page 685).

Tests.—"It should not deposit a sediment on keeping, and should not tinge gelatinized starch blue (absence of free iodine). 10 Gm. of the syrup should require for complete precipitation not less than 1.09 Gm. of nitrate of silver (corresponding to 10 per cent. of ferrous iodide)."—*U. S.*

The syrup of the French Codex is flavored with orange-flower water and contains gum; the solution of ferrous iodide is filtered, afterward mixed with syrup, and finally protected from the light.

Medical Uses.—In the treatment of *scrofula*, especially of the glandular form, in those numerous cases in which *anæmia* is owing to scrofula, tuberculosis, or syphilis, and in chronic affections of the *skin*, chronic *rheumatism*, *amenorrhœa* from exhaustion, *leucorrhœa*, etc., this compound was at one time greatly in vogue. It is now, however, very probable that its alleged virtues in the greater number of those diseases depended more upon the iron than upon the iodine in its composition. It has the disadvantage of being the least agreeable in its taste of all the official preparation of iron. This syrup may be given in *doses* of from 10 to 40 drops (Gm. 0.50–2.50) after meals. It should be largely diluted with water, and taken through a tube to prevent its injuring the teeth. As an additional precaution the mouth should be rinsed with water after each dose.

SYRUPUS FERRI PHOSPHATIS, Br.—SYRUP OF PHOSPHATE OF IRON.

Sirop de phosphate de fer, Fr.; Eisenphosphatsyrup, G.

Preparation.—Take of Granulated Sulphate of iron 224 grains; Phosphate of Sodium 200 grains; Bicarbonate of Sodium 56 grains; Concentrated Phosphoric Acid 14 fluidounces; Refined Sugar 8 ounces; Distilled Water 8 fluidounces. Dissolve the sulphate of iron in 4 ounces of boiling water, and the phosphate of sodium in a similar quantity of cold water; mix the solutions, add the bicarbonate of sodium dissolved in a little water, and, after careful stirring, transfer the precipitate to a calico filter, and wash it with distilled water till the filtrate ceases to be affected by chloride of barium. Mix the residue on the filter in a mortar with the phosphoric acid. As soon as the precipitate is dissolved, filter the solution, add water and the sugar, and dissolve without heat. The product should measure exactly 12 fluidounces, any water which may be necessary beyond that introduced with the precipitate or with the sugar being added to form the stated bulk.—Br.

Sulphate of iron and phosphate of sodium react on each other, forming ferrous phosphate and sulphate of sodium, the resulting free sulphuric acid, which would keep a portion of the ferrous phosphate in solution, being nearly neutralized with sodium bicarbonate. (See FERRI PHOSPHAS, p. 692.) After washing, the precipitate is dissolved in phosphoric acid, and this solution is converted into syrup, which is therefore presumed to contain acid ferrous phosphate. But during the washing the originally white precipitate has turned blue from the formation of ferroso-ferrie phosphate, and this oxidation continues to some extent in the syrup notwithstanding the protective influence of the sugar. The change produced in the color of the syrup on exposure is thus accounted for. The syrup has the density 1.305, and 1 fluidrachm contains about 1 grain of anhydrous ferrous phosphate.

Allied Syrups.—SYRUP OF PYROPHOSPHATE OF IRON is made by dissolving 10 parts of the official pyrophosphate of iron in 20 parts of water, and adding 970 parts of simple syrup (*F. Cod.*). This syrup contains 1 per cent. of the salt, and has a green color.

Numerous other formulas for syrups containing phosphate of iron in solution have been proposed, in some of which the free phosphoric acid has been wholly or partly replaced by hydrochloric acid, resulting in the formation of ferric chloride. H. W. Jones (1875) showed that a more satisfactory syrup is obtained by preparing the ferrous phosphate from iron and phosphoric acid; and E. B. Shuttleworth (1876) proposed the following formula: 38 grains of clean iron filings or fine iron wire are dissolved in a mixture of 6 fluidrachms each of water and phosphoric acid spec. grav. 1.5; the solution is filtered as soon as the iron is dissolved and mixed with 8½ fluidounces of simple syrup. Thus prepared, it is free from ferric salt, but otherwise represents the official syrup, and contains 1 grain of phosphate in the fluidrachm. Mr. Howie (1877) suggested dispensing with the acetate of sodium of the official formula, mixing the solutions of the other two salts while boiling hot, letting the mixture cool to about 50° C. (122° F.), and adding 45 grains of bicarbonate of sodium; the precipitate is washed with boiling water by decantation, and subsequently treated as directed in the official formula.

SYRUPUS PHOSPHATUM COMPOSITUS, or CHEMICAL FOOD. This was proposed by Edward Parrish (1857), whose formula is as follows: 600 grains of ferrous sulphate and 720 grains of sodium phosphate are separately dissolved in boiling water, the solutions mixed, and the precipitate thoroughly washed; 720 grains of calcium phosphate are dissolved in 4 ounces of hot water with the aid of hydrochloric acid; the solution is precipitated by ammonia and the precipitate well washed. The recently-obtained phosphates are dissolved in 1200 grains of glacial phosphoric acid previously dissolved in water; 40 grains of carbonate of sodium and 60 grains of carbonate of potassium are added to the solution, and if a precipitate should form it is redissolved by sufficient hydrochloric, or, preferably, by phosphoric, acid. The solution is now diluted with water to 20 fluidounces; 120 grains of powdered cochineal and 36 troyounces of sugar are added, and when the latter is dissolved the syrup is strained and flavored with 10 minims of oil of orange. Each teaspoonful is stated to contain about 1 grain of phosphate of iron, 2½ grains of phosphate of calcium, and smaller proportions of the phosphates of sodium and potassium. E. C. Saunders (1876), however, showed that a syrup thus prepared cannot contain the amounts of phosphates stated, and proposed to dissolve 240 grains of fine iron wire in 3 ounces (avoirdupois) of tribasic phosphoric acid spec. grav. 1.75 and 4 ounces of water; 923 grains of recently-slaked lime in 9½ ounces of phosphoric acid and 14 ounces of water; and 54 grains of crystallized sodium carbonate and 72 grains of potassium carbonate in ½ ounce of the phosphoric acid and 1 ounce of water. The three solutions are mixed and diluted with water to the measure of 28 fluidounces; the mixture, with 52 ounces of sugar and 85 grains of powdered cochineal, is made into a syrup, and this is flavored with 2 fluidounces of orange-flower water and diluted with water to 64 fluidounces.

Medical Uses.—This is a convenient and mild preparation of iron, which is assumed to have a special influence upon the nervous system. The dose is 1 fluidrachm (Gm. 4). Other non-official syrups have been devised, such as those above described, which, besides phosphorus and iron, contain lime, soda, and potassa, or else quinine and strychnine.

The latter are the most efficient. They have the disadvantage in many cases, however, of confining the bowels.

SYRUPUS FERRI QUININÆ ET STRYCHNINÆ PHOSPHATUM, U. S.—SYRUP OF THE PHOSPHATES OF IRON, QUININE, AND STRYCHNINE.

Syrupus ferri phosphorici cum chinino et strychnino, Syrupus Edtoni.—*Sirop tonique d'Edton, Fr.; Edton's syrup, G.*

Preparation.—Phosphate of Iron 133 parts (200 grains); Quinine 133 parts (200 grains); Strychnine 4 parts (6 grains); Phosphoric Acid 800 parts (1200 grains or $2\frac{3}{4}$ oz. av.); Sugar, in coarse powder, 6000 parts (9000 grains or $20\frac{5}{8}$ oz. av.); Distilled Water a sufficient quantity; to make 10,000 parts (15,000 grains = $34\frac{1}{4}$ oz. av. or about 24 fluidounces). Add the phosphate of iron to 2500 parts ($8\frac{1}{2}$ oz. av. or 8 fluidounces) of distilled water in a tared bottle large enough to hold the finished syrup, and agitate frequently until the salt is dissolved. Having added the phosphoric acid to the solution, triturate the quinine and strychnine gradually with the mixture in a mortar until they are dissolved; then return the solution to the bottle and add enough distilled water to make the liquid weigh 4000 parts (6000 grains = $13\frac{3}{4}$ oz. av.). Lastly, add the sugar, dissolve it by agitation, without heat, and filter through paper. Keep the syrup in small, well-stopped vials in a cool and dark place.—U. S.

This syrup is known as *Edton's syrup*. In the original formula freshly-precipitated ferrous phosphate was dissolved in phosphoric acid, and subsequently became oxidized on exposure to ferric salt. The phosphate of iron now employed is the pharmacopœial sealed sodio-ferric citrophosphate (see p. 691).

Medical Uses.—The association of iron, quinine, and strychnine is a very valuable one, but it is not judicious to make use of a preparation in which their proportion to one another is invariable, nor of one whose solid bulk is mainly sugar. Moreover, the present preparation is very liable to undergo changes that impair its qualities. *Dose*, 1 or 2 teaspoonfuls (Gm. 4–8).

SYRUPUS HEMIDESMI, Br.—SYRUP OF HEMIDESMUS.

Sirop de hemidesmus, Fr.; Hemidesmussyrup, G.

Preparation.—Take of Hemidesmus-Root, bruised, 4 ounces; Refined Sugar 28 ounces; boiling Distilled Water 1 pint (Imperial). Infuse the hemidesmus in the water, in a covered vessel, for four hours, and strain. Set it by till the sediment subsides; then decant the clear liquor, add the sugar, and dissolve by means of a gentle heat. The product should weigh 2 pounds 10 ounces, and should have the specific gravity 1.335.

—Br.

Medical Uses.—The syrup of Indian sarsaparilla probably possesses no definite or peculiar medicinal virtues; it is used chiefly as a flavoring agent.

SYRUPUS HYPOPHOSPHITUM, U. S.—SYRUP OF HYPOPHOSPHITES.

Syrupus calcii hypophosphitis compositus.—*Sirop d'hypophosphite de chaux composé, Fr.; Hypophosphitsyrup, G.*

Preparation.—Hypophosphite of Calcium 35 parts (700 grains = $1\frac{1}{2}$ oz. av. and 44 grains); Hypophosphite of Sodium 12 parts (240 grains); Hypophosphite of Potassium 12 parts (240 grains); Citric Acid 1 part (20 grains); Spirit of Lemon 2 parts (40 grains or 50 minims); Sugar, in coarse powder, 500 parts (10,000 grains = $22\frac{5}{8}$ oz. av.); Water a sufficient quantity; to make 1000 parts ($45\frac{3}{4}$ oz. av. or about 2 pints). Mix the hypophosphites, and dissolve them, by trituration, in 350 parts (16 oz. av. or $15\frac{3}{8}$ fluidounces) of water. Should there be a trifling residue undissolved, allow the solution to settle, pour off nearly all of it, and add the citric acid so that the residue may be dissolved. Then, having mixed the liquids, add the spirit of lemon, and filter through paper, adding through the filter enough water to make the whole weigh 500 parts ($22\frac{5}{8}$ oz. av.). In this liquid dissolve the sugar by agitation without heat, and strain. Keep the syrup in well-stopped bottles.—U. S.

Medical Uses.—As we have elsewhere insisted, there is no ground for believing in the efficiency of the pharmaceutical hypophosphites. The dose of this preparation has been stated at from $\frac{1}{2}$ to 1 fluidrachm (Gm. 2–4), but no reason appears why more or less than this would not be quite as efficient.

SYRUPUS HYPOPHOSPHITUM CUM FERRO.—SYRUP OF HYPOPHOSPHITES WITH IRON.

Preparation.—Lactate of Iron 1 part (100 grains); Syrup of Hypophosphites 99 parts (9900 grains = $22\frac{5}{8}$ oz. av. or about 1 pint); to make 100 parts (10,000 grains = $22\frac{5}{8}$ oz. av.). Dissolve the lactate of iron in the syrup by trituration. Keep the syrup in well-stopped bottles.—*U. S.*

This and the preceding syrup have been in use since 1857, but have been admitted into the Pharmacopœia for the first time in 1880. Formerly hypophosphite of iron was used, but this salt has been replaced in the above formula by the lactate. In preparing both syrups heat should be avoided, and they should be kept in well-stopped bottles to lessen the chances of gradual oxidation.

Medical Uses.—The remarks made on the analogous preparation immediately preceding apply to this one also. *Dose*, $\frac{1}{2}$ to 1 fluidrachm (Gm. 2–4).

SYRUPUS IPECACUANHÆ, *U. S.*, *P. G.*—SYRUP OF IPECAC.

Sirap d'ipécacuanha, Fr.; *Ipecacuanhasyrup*, G.

Preparation.—Fluid Extract of Ipecac 5 parts (500 grains); Syrup 95 parts (9500 grains = $21\frac{1}{4}$ oz. av.); to make 100 parts (10,000 grains = $22\frac{5}{8}$ oz. av. or about 17 fluidounces). Mix them.—*U. S.*

The difficulties encountered in the preparation of fluid extract of ipecac which would mix with water without turbidity have been explained on page 641. The mixture of fluid extract and syrup is usually clear in the beginning, but a flocculent matter begins to separate after some time, and settles slowly. In this case it is best to modify the process as follows: Dilute 500 grains of the fluid extract with 7 oz. av. of distilled water, and set aside for a day; then pass through a filter and wash the precipitate with distilled water until the filtrate weighs $8\frac{3}{4}$ oz. av.; in this liquid dissolve $14\frac{1}{2}$ oz. av. of sugar, either by agitation or preferably by percolation. In this connection an inconsistency of the present *U. S. Pharmacopœia* should be noticed in directing the fluid extracts to be prepared measure for weight, and in weighing these same fluid extracts when using them for other preparations. Since the density of fluid extracts must necessarily vary somewhat, syrup of ipecac and similar preparations will obviously represent only approximately definite weights of the drug.

The syrup of the German Pharmacopœia represents 1 per cent. of its weight of ipecacuanha-root, and that of the French Codex 1 per cent. of extract of ipecacuanha.

Medical Uses.—This syrup is used chiefly as an emetic for infants, and as an expectorant in cases of acute *laryngitis* and *bronchitis*. For the former purpose the dose is from $\frac{1}{2}$ to 1 fluidrachm (Gm. 2–4), repeated every ten minutes until it operates; and for the latter it may be given to infants and children in doses of from 5 to 20 drops (Gm. 0.30–1.30), and to adults in double those quantities. It forms a very useful ingredient of expectorant mixtures in the diseases named.

SYRUPUS KRAMERLÆ, *U. S.*—SYRUP OF KRAMERIA.

Syrupus ratanhæ.—*Syrup of rhatany*, E.; *Sirap de ratanhia*, Fr.; *Ratanhasyrup*, G.

Preparation.—Fluid Extract of Krameria 35 parts (7 oz. av.); Syrup 65 parts (13 oz. av.); to make 100 parts (20 oz. av.). Mix them.—*U. S.*

The *U. S. P.* 1870 directed for this syrup the mixing of fluid extract of rhatany 12 fluidounces and syrup 24 fluidounces. The present fluid extract is about 5 per cent. weaker. The syrup of the French Codex is made with the aqueous extract of rhatany, of which it contains 2.5 per cent. of its weight.

SYRUPUS IODO-TANNICUS (see also p. 833). Guilliermond recommends extract of rhatany for this syrup, which may be made by dissolving 2 grains of iodine, with a little alcohol, in 200 grains of syrupus kramerie (*U. S. P.*), and adding 800 grains of simple syrup.

Medical Uses.—Syrup of rhatany is chiefly used as a medicine for infants and children affected with *bowel complaints* independent of organic or inflammatory disease, and is usually associated in mixtures with chalk and other antacids and astringents. The *dose* for a child a year or two old is from $\frac{1}{2}$ to 1 fluidrachm (Gm. 2–4).

SYRUPUS LACTUCARII, U. S.—SYRUP OF LACTUCARIUM.

Sirop de lactucarium, Fr.; *Lactucariumsyrup*, G.

Preparation.—Fluid Extract of Lactucarium 5 parts (500 grains); Syrup 95 parts (9500 grains = 21½ oz. av.), to make 100 parts (10,000 grains = 22½ oz. av. or about 17 fluidounces). Mix them.—*U. S.*

As formerly prepared, syrup of lactucarium was of a turbid and unsightly appearance. Since alkalies destroy the bitter taste of lactucarium, neither potassa, soda, nor magnesia should be used in making the syrup. The turbidity was due to lactucerin, and could be removed, according to Kenworthy (1868), without impairing the virtues of the syrup by triturating the concentrated tincture with powdered pumice-stone, or, according to Lemberger (1878), by previously exhausting lactucarium with petroleum benzin. Paper-pulp or other insoluble material may be used with the same effect. But the present fluid extract, if properly prepared, will yield a clear mixture with syrup, which may be prepared extemporaneously.

SIROP DE LACTUCARIUM OPIACÉ, *F. Cod.*, contains in each tablespoonful 0.005 Gm. ($\frac{1}{4}$ grain) of extract of opium and 0.01 Gm. ($\frac{1}{4}$ grain) of alcoholic extract of lactucarium.

Medical Uses.—It is very doubtful whether this preparation possesses any hypnotic powers at all. It may be used as a *placebo* for mothers in certain cases of infantile disorder in the *dose* of 1 or more fluidrachms (Gm. 4).

SYRUPUS LIMONIS, U. S., Br.—SYRUP OF LEMON.

Syrupus succi citri.—*Sirop de suc de limon (de citron)*, Fr.; *Citronensyrup*, G.

Preparation.—Lemon-Juice, recently expressed and strained, 40 parts (20 oz. av.); Fresh Lemon-Peel 2 parts (1 oz. av.); Sugar, in coarse powder, 60 parts (30 oz. av.); Water a sufficient quantity; to make 100 parts (50 oz. av. or about 2½ pints). Heat the lemon-juice to the boiling point; then add the lemon-peel, and let the whole stand, closely covered, until cold. Filter, add enough water through the filter to make the filtrate weigh 40 parts (20 oz. av.), dissolve the sugar in the filtered liquid by agitation without heat, and strain.—*U. S.*

The present formula is nearly identical with that of the Br. P., which differs in ordering 2 ounces of lemon-peel and 36 ounces of sugar. The U. S. P. 1870 omitted the lemon-peel, and its syrup was but slightly aromatic.

Medical Uses.—This syrup is scarcely medicinal. It is used habitually with water as a beverage, and thus forms a pleasant and suitable drink in febrile affections generally, especially when mixed with carbonic acid water.

SYRUPUS MORI, Br.—SYRUP OF MULBERRIES.

Syrupus mororum.—*Sirop de mûre*, Fr.; *Maulbeersaft*, G.

Preparation.—Take of Mulberry-Juice 1 pint (Imperial); Refined Sugar 2½ pounds; Rectified Spirit 2½ fluidounces. Heat the mulberry-juice to the boiling-point, and when it has cooled filter it. Dissolve the sugar in the filtered liquid with a gentle heat, and add the spirit. The product should weigh 3 pounds 6 ounces, and should have the specific gravity 1.33.—*Br.*

This and all other syrups of acid fruit-juice should be prepared only in porcelain or well-enamelled iron vessels. The heating of the juice to the boiling-point has for its object the removal of the albumen.

The fruit syrups of the French Codex and of the German Pharmacopœia, with the exception of lemon syrup, are made with the fermented juice. (See SYRUPUS RUBI IDÆI.)

Medical Uses.—In this country syrups made from currants, raspberries, and strawberries are as commonly used as mulberry syrup and mulberry wine are in England. Mulberry syrup has no therapeutic virtues which are not possessed by the other syrups mentioned.

SYRUPUS PAPAVERIS, Br., P. G.—SYRUP OF POPPIES.

Syrupus capitum papaveris, Syrupus diacodii.—*Sirop de pavot blanc*, Fr.; *Beruhigungs-saft*, G.

Preparation.—Take of Poppy-Capsules, dried, freed from the seeds, and coarsely powdered, 36 ounces; Rectified Spirit 16 fluidounces; Refined Sugar 4 pounds; boiling Distilled Water a sufficiency. Mix the poppy-capsules with 4 pints of the water and infuse for 24 hours, stirring them frequently; then pack them in a percolator, and, adding more of the water, allow the liquor slowly to pass until about 2 gallons have been collected or the poppies are exhausted. Evaporate the liquor by a water-bath, until it is reduced to 3 pints (Imperial). When quite cold, add the spirit, let the mixture stand for 12 hours, and filter. Distil off the spirit, evaporate the remaining liquor to 2 pints, and then add the sugar. The product should weigh 6½ pounds, and should have the specific gravity 1.330.—*Br.*

The concentrated infusion of poppy contains much mucilage, which is precipitated by the alcohol. This syrup is less liable to ferment than if prepared from an infusion not subjected to the treatment with alcohol and is nearly six times stronger in poppy-capsules than that of the P. G. The syrup was formerly often prepared from the hot infusion of poppy-capsules, St. John's bread, and liquorice-root. On account of the variable composition of poppy-capsules the French Codex directs this syrup to be prepared by dissolving 1 part of alcoholic extract of poppy in 3 parts of alcohol, and mixing with 96 parts of syrup. *Sirop diacode* is a solution of ½ grain, and *sirop d'opium* a solution of 2 grains, of extract of opium in 1000 grains of simple syrup; *syrupus opiatus* (P. G. 1872) contained 1 grain of the extract in the same amount of syrup.

Medical Uses.—The variable proportion of opium in poppy-capsules renders this preparation uncertain in its effects, and therefore capable of doing serious injury to young children, the class of persons it is intended for especially. It is far better to add a definite proportion of a liquid preparation of opium or of morphine to syrup of acacia, of marshmallow, or of wild-cherry if a weak anodyne or narcotic action is required. The dose of this syrup is stated to be ½ fluidrachm (Gm. 2) for young children.

SYRUPUS PICIS LIQUIDÆ, U. S.—SYRUP OF TAR.

Syrupus piceus.—*Sirop de goudron*, Fr.; *Theersyrup*, G.

Preparation.—Tar 6 parts (3 oz. av.); Cold Water 12 parts (6 oz. av. or 5¾ fluidounces); boiling Distilled Water 50 parts (25 oz. av. or 24 fluidounces); Sugar, in coarse powder, 60 parts (30 oz. av.); to make 100 parts (50 oz. av. or about 2¼ pints). Upon the tar, contained in a suitable vessel, pour the cold water, and stir the mixture frequently during 24 hours; then pour off the water and throw it away. Pour the boiling distilled water upon the residue, stir the mixture briskly for 15 minutes, and set it aside for 36 hours, stirring occasionally. Decant the solution and filter. Lastly, in 40 parts (20 oz. av. or 19½ fluidounces) of the filtered solution dissolve the sugar by agitation, without heat.—*U. S.*

This formula is very similar to that of the French Codex of 1866. The tar is first treated with water for the purpose of removing most of the acetic acid present, and this infusion is rejected. The various soluble constituents of tar are then extracted by hot water, as directed above, or by one of the methods described on page 1182; in the tar-water thus obtained the sugar is dissolved by agitation or by percolation. Thus prepared, the syrup is of a yellowish color, has the odor of tar, a slightly bitter taste, and an acid reaction, and when rendered alkaline becomes brown.

SYRUPUS PICIS IODATUS, *Sirop de goudron iodé*, is much employed in France, and contains $\frac{1}{10}$ per cent. of iodine. 1 grain of iodine dissolved in a little alcohol is added, with agitation, to 1000 grains of syrup of tar; the color of iodine will disappear in a few days, when the iodized syrup has about the same color as tar syrup.

Medical Uses.—It may be questioned whether the sugar in this preparation of tar-water does not impair the activity of the medicine, and partly so by retarding its absorption. The dose may be stated at from a tablespoonful to a wine-glassful (Gm. 16–64) according to the age of the patient and the tolerance of his stomach.

SYRUPUS PRUNI VIRGINIANÆ, U. S.—SYRUP OF WILD-CHERRY.

Sirop d'écorce de cerisier, Fr.; *Wildkirschenrindensyrup*, G.

Preparation.—Wild-Cherry, in No. 20 powder, 12 parts (6 oz. av.); Sugar, in coarse powder, 60 parts (30 oz. av.); Glycerin 5 parts (2½ oz. av.); Water a sufficient quantity; to make 100 parts (50 oz. av. or about 2½ pints). Moisten the wild-cherry thoroughly with water, and macerate for 24 hours in a close vessel; then pack it firmly in a cylindrical glass percolator, and gradually pour water upon it until 35 parts (17½ oz. av. or about 16 fluidounces) of percolate are obtained. Dissolve the sugar in the liquid by agitation, without heat, add the glycerin, and strain.—U. S.

The treatment of wild-cherry bark with cold water results in the production of hydrocyanic acid and oil of bitter almond (see page 1248), which, together with the bitter and astringent principles, are contained in the syrup, which has a rich brownish-red color and a pleasant taste. A formula for this preparation was proposed by Procter and Turnpenny in 1842, and the substitution of glycerin for a portion of the sugar was suggested by C. Schnabel (1874) for the purpose of preventing fermentation. A still larger proportion of glycerin was recommended by W. H. Walling (1874).

Medical Uses.—Syrup of wild-cherry has no peculiar medicinal virtues, but is a most agreeable flavoring addition to mixtures. It is often added to such under the impression that it may aid in appeasing cough. The *dose* is a fluidrachm (Gm. 4) or more.

SYRUPUS RHAMNI.—SYRUP OF BUCKTHORN.

Syrupus rhamni cathartice, s. *Syr. spinæ cervinæ*, s. *Syr. domesticus*, P. G.—*Sirop de nerprun*, Fr.; *Kreuzdornbeerensyrup*, G.

Preparation.—Take of Buckthorn-Juice 4 pints; Ginger, sliced, Pimento, bruised, each ¾ ounce; Refined Sugar 5 pounds or a sufficiency; Rectified Spirit 6 fluidounces. Evaporate the juice to 2½ pints (Imperial), add the ginger and pimento, digest at a gentle heat for 4 hours, and strain. When cold add the spirit; let the mixture stand for 2 days, then decant off the clear liquor, and in this dissolve the sugar with a gentle heat, so as to make the specific gravity 1.32.—Br., 1867.

This syrup is made by the French and German Pharmacopœias with the fermented juice not concentrated by evaporation, and does not contain any aromatics.

Medical Uses.—In Europe syrup of buckthorn is generally used as a purgative for children in the *dose* of a teaspoonful (Gm. 4).

SYRUPUS RHEI, U. S., Br., P. G.—SYRUP OF RHUBARB.

Sirop de rhubarbe, Fr.; *Rhabbarbersaft*, G.

Preparation.—Rhubarb, sliced, 90 parts (3¾ oz. av.); Cinnamon, bruised, 18 parts (¾ oz. av.); Carbonate of Potassium 6 parts (¼ oz. av.); Sugar, in coarse powder, 600 parts (25 oz. av.); Water a sufficient quantity; to make 1000 parts (41¾ oz. av. or about 30 fluidounces). Mix the rhubarb, cinnamon, and carbonate of potassium with 420 parts (17½ oz. av. or 16¾ fluidounces) of water, and macerate the mixture in a glass or porcelain vessel for 12 hours. Then strain and filter, adding through the dregs, if necessary, enough water to make the filtered liquid weigh 400 parts (16¾ oz. av.). Lastly, add the sugar, dissolve it by agitation without heat, and strain.—U. S.

Take of rhubarb-root, in No. 20 powder, coriander-fruit, in No. 20 powder, each 2 ounces; refined sugar 24 ounces; rectified spirit 8 fluidounces; distilled water 24 fluidounces. Mix the rhubarb and coriander; pack them in a percolator; pass the spirit and water previously mixed slowly through them; evaporate the liquid that has thus passed until it is reduced to 14 fluidounces, and in this, after it has been filtered, dissolve the sugar with the aid of heat. The product should weigh nearly 2½ pounds.—Br.

The first formula is that of the German Pharmacopœia, with some modifications, the most important being the reduction of potassium carbonate from 9 to 6 parts, and the apparent strength of the syrup, 90 parts of rhubarb yielding 1000 parts (U. S.) and 1800 parts (P. G.) of finished syrup; the manipulation is alike in both cases, and involves considerable waste of material. Rhubarb yields to cold water about 40 per cent. of extractive matters, to alkaline liquids somewhat more; 90 parts of rhubarb therefore yield at least 36 parts of soluble matter, and, without taking into consideration the soluble matter yielded by the cinnamon, the actual weight of the solution is 420 (water) + 6 (potassium

carbonate) + 36 (from rhubarb) = 462 parts. Of this at most 400 parts are obtained by expressing and washing, and the loss amounts to at least 62 parts or 13.4 per cent. It is, however, actually greater, since by adding water through the dregs (expression is not directed, but is indispensable) the solution is considerably diluted, instead of being simply displaced. The German Pharmacopœia directs for 90 parts of rhubarb 900 parts of water, and after expressing and filtering obtains 720 parts of liquid; the waste is proportionally greater.

The present syrup is of a deep brown-red color, and is transparent in thin layers; the presence of alkali renders it unfit for combination with various salts, which are precipitated thereby. The syrup of the Br. P. is of a deep-brown color and somewhat opaque, and of a similar appearance was the syrup of rhubarb as prepared by the U. S. P. 1870 by mixing 3 fluidounces of fluid extract of rhubarb with 29 fluidounces of simple syrup.

Medical Uses.—The simple syrup of rhubarb is seldom used, but it may be given as a purgative to infants in the *dose* of a fluidrachm (Gm. 4).

SYRUPUS RHEI AROMATICUS, U. S.—AROMATIC SYRUP OF RHUBARB.

Spiced syrup of rhubarb, E.; *Sirop de rhubarbe aromatique*, Fr.; *Gewürzter Rhubarbersaft*, G.

Preparation.—Aromatic Tincture of Rhubarb 10 parts (2 oz. av.); Syrup 90 parts (18 oz. av.); to make 100 parts (20 oz. av. or about 15 fluidounces). Mix the aromatic tincture of rhubarb with the syrup.—*U. S.*

The aromatic tincture of rhubarb, which was formerly prepared to be at once mixed with the syrup, is now recognized as a distinct preparation. The syrup is of about the same strength as that of the former Pharmacopœia, which directed 1 part by measure of the tincture to 6 parts by measure of simple syrup; it has an agreeable odor, a spicy and bitterish but pleasant taste, and is somewhat opaque in appearance.

Medical Uses.—This preparation is in universal use as a purgative for children in *diarrhœa* attended with flatulence and colic. The *dose* is 1 fluidrachm (Gm. 4).

SYRUPUS RHEADOS, Br.—SYRUP OF RED POPPY.

Sirop de coquelicot, de pavot rouge, Fr.; *Klatschrosensaft*, G.

Preparation.—Take of fresh Red Poppy-Petals 13 ounces; Refined Sugar 21 pounds; Distilled Water 1 pint (Imperial) or a sufficiency; Rectified Spirit 2½ fluidounces. Add the petals gradually to the water heated in a water-bath, frequently stirring, and afterward, the vessel being removed, infuse for 12 hours. Then press out the liquor, strain, add the sugar, and dissolve by means of heat. When nearly cold add the spirit and as much distilled water as may be necessary to make up for loss in the process, so that the product shall weigh 3 pounds 10 ounces. It should have the specific gravity 1.33.—*Br.*

The addition of alcohol to the finished syrup is designed to counteract its tendency to fermentation. The syrup is of a deep-red color.

Medical Uses.—The syrup of red poppy is an opiate preparation of uncertain strength, and, being only used for coloring mixtures, it appears to be superfluous. The *dose* is a fluidrachm (Gm. 4).

SYRUPUS ROSÆ, U. S.—SYRUP OF ROSE.

Syrupus rosæ gallicæ, U. S. 1870, Br.; *Syrupus rosarum rubrarum*.—*Syrup of red rose*, E.; *Sirop de roses rouges*, Fr.; *Rosensyrup*, G.

Preparation.—Fluid Extract of Rose 10 parts (2 oz. av.); Syrup 90 parts (18 oz. av.); to make 100 parts (20 oz. av. or about 15 fluidounces). Mix them.—*U. S.*

Take of dried red rose petals 2 ounces; refined sugar 30 ounces; boiling distilled water 1 pint. Infuse the petals in the water for 2 hours; squeeze through calico, heat the liquor to the boiling point, and filter. Dissolve the sugar in the liquor by means of heat. The product should weigh 2 pounds 14 ounces, and should have the specific gravity 1.335.—*Br.*

The syrup is of a fine red color and has an agreeable somewhat astringent taste.

Medical Uses.—It is used almost exclusively for giving an agreeable color and flavor to other syrups and to mixtures. *Dose*, a fluidrachm (Gm. 4).

SYRUPUS RUBI, U. S.—SYRUP OF RUBUS.

Syrup of blackberry-bark, E.; Sirop de écorce de ronce, Fr.; Brombeerrindensyrup, G.

Preparation.—Fluid Extract of Rubus 20 parts (4 oz. av.); Syrup 80 parts (16 oz. av.); to make 100 parts (20 oz. av. or about 1 pint). Mix them.—*U. S.*

This syrup has a deep reddish-brown color and a strongly astringent taste.

Medical Uses.—As a remedy for slight *diarrhœa* independent of irritants in the intestine and of inflammatory conditions of that organ syrup of blackberry-root is a convenient astringent. But the syrup is generally less appropriate than the decoction. Its *dose* is 1 or 2 fluidrachms (Gm. 4–8).

SYRUPUS RUBI IDÆI, U. S., P. G.—SYRUP OF RASPBERRY.

Sirop de framboise, Fr.; Himbeersaft, G.

Preparation.—Fresh Ripe Raspberries any convenient quantity; Sugar a sufficient quantity. Reduce the raspberries to a pulp, and let it stand at rest for 3 days. Separate the juice by pressing, and set it aside until it has completely fermented and become clear, and then filter. To 40 parts of the filtered liquid add 60 parts of sugar, heat to boiling, avoiding the use of tinned vessels, and strain. Keep the syrup in well-stopped bottles in a cool and dark place.—*U. S.*

This formula has been taken from the P. G. 1872, and, if the temperature be kept low enough after bruising the raspberries, will yield good results; during the warm summer months, however, when fresh raspberries are procurable, acetic fermentation will set in. The new French Codex directs the fresh fruit to be expressed and the juice to be fermented at a temperature of 12° to 15° C. (54°–59° F.), fermentation to be arrested as soon as the liquid will readily pass through a filter; otherwise the flavor will be much impaired. The present P. G. gives the following directions: "Bruise the raspberries, set them aside, at about 20° C. (68° F.), in a covered vessel; stir frequently, and when a filtered portion of the juice may be mixed with half its bulk of alcohol without becoming turbid express and filter." Other fruit-juices are prepared in precisely the same manner. The juice of ripe raspberries ferments readily, and the fermentation is completed in a few hours or a day, according to the temperature. The formation of mould and acetic fermentation impair the flavor; the progress of fermentation should therefore be closely watched, and the expressed juice should be rapidly filtered and at once converted into syrup. Fruit-syrups contain 59.3 (*Br.*), 60 (*U. S.*), 63.7 (*F. Cod.*), and 65 (*P. G.*) per cent. of sugar.

Properties.—Raspberry syrup has a bright-red color, a very agreeable fruit odor, a pleasant acidulous taste, and a distinct acid reaction. When agitated with amylie alcohol, ether, or chloroform, these liquids are not colored. On being rendered alkaline the syrup becomes dark-blue or dingy-violet colored, and when treated with basic lead acetate a dingy-blue or blue-green precipitate is produced, the filtrate being colorless or nearly so. When strongly acidulated with cold nitric acid the red color is not changed to yellow. These reactions serve to distinguish raspberry syrup from imitations colored with aniline-red or with other coloring matters of vegetable origin.

Allied Preparations.—SYRUPUS CERASORUM, *P. G.*—Cherry syrup, *E.*; Sirop de cerise, *Fr.*; Kirschsyrup, *G.*—The juice of black cherries is fermented in the presence of the bruised seeds, and further treated as stated above.

SYRUPUS CYDONIÆ (quince syrup), *Syr. fragariæ* (strawberry syrup), *Syr. granati* (pomegranate syrup), and others are prepared in a similar manner, the ripe fruits being used. (See also *SYR. MORI* and *SYR. RHAMNI*).

ACETUM RUBI IDÆI.—Raspberry vinegar, *E.*; Vinaigre framboisé, *Fr.*; Himbeerssigg, *G.*—Mix equal parts of syrup of raspberry and of vinegar.—*F. Cod.* Raspberry syrup 1 part, pure vinegar 2 parts.—*P. G.* 1872. Other fruit-vinegars may be made in the same manner.

AQUA RUBI IDÆI.—Raspberry-water, *E.*; Eau de framboise, *Fr.*; Himbeerwasser, *G.*—Distil 2 parts of water from 1 part of the press-cake left on clarifying raspberry-juice as described above.—*P. G.* 1872. It has an agreeable fruit odor. *Strawberry-water* is made in the same manner; it is sometimes used as a cosmetic.

Medical Uses.—This syrup has no special medicinal virtues. It forms an agreeable flavoring addition to mixtures, and with water a pleasant drink in febrile affections.

SYRUPUS SARSAPARILLÆ COMPOSITUS, U. S.—COMPOUND SYRUP OF SARSAPARILLA.

Syrupus sudorificus.—*Sirap de salsepareille composé, Sirap sudorifique*, Fr.; *Zusammengesetzter Sarsaparillsyrup*, G.

Preparation.—Sarsaparilla, in No. 30 powder, 150 parts ($12\frac{1}{2}$ oz. av.); Guaiacum-Wood, in No. 30 powder, 20 parts ($1\frac{3}{4}$ oz. av.); Pale Rose, in No. 30 powder, 12 parts (1 oz. av.); Glycyrrhiza, in No. 30 powder, 12 parts (1 oz. av.); Senna, in No. 30 powder, 12 parts (1 oz. av.); Sassafras, in No. 20 powder, 6 parts ($\frac{1}{2}$ oz. av.); Anise, in No. 20 powder, 6 parts ($\frac{1}{2}$ oz. av.); Gaultheria, in No. 20 powder, 6 parts ($\frac{1}{2}$ oz. av.); Sugar, in coarse powder, 600 parts (50 oz. av.); Diluted Alcohol, Water, each a sufficient quantity; to make 1000 parts ($83\frac{1}{4}$ oz. av. or about 60 fluidounces). Mix the solid ingredients, except the sugar, with 300 parts (25 oz. av. or $25\frac{7}{8}$ fluidounces) of diluted alcohol, and macerate the mixture for 48 hours; then transfer it to a cylindrical percolator, pack it firmly, and gradually pour diluted alcohol upon it until 600 parts (50 oz. av. or about 3 pints) of tincture have been obtained. Evaporate this portion, by means of a water-bath, to 300 parts (25 oz. av. or about $1\frac{1}{2}$ pints); add 100 parts ($8\frac{1}{4}$ oz. av.) of water, and filter, adding enough water through the filter to make the whole weigh 400 parts ($33\frac{1}{4}$ oz. av. or about 2 pints). Lastly, add the sugar, dissolve it by agitation without heat, and strain.

By careful percolation with diluted alcohol the medicinal principles of the drugs ordered in the above formula are thoroughly extracted, with the exception of the resin contained in guaiacum-wood, and are not injured if the alcohol of the tincture is evaporated at a heat not exceeding the temperature attainable by a water-bath. In the watery liquid now remaining the resinous matters which were dissolved by the alcohol are insoluble, and are removed by filtration; the filtrate therefore contains only the extractive matters of guaiacum-wood, but none, or only little, of its resin. The volatile oils taken up from the sassafras, anise, and gaultheria are partly volatilized during the evaporation; the heat should therefore be as low as possible in this operation, and the sugar should be dissolved in the filtered liquid by percolation, which, owing to frothing, is far preferable to agitation. The former Pharmacopœia did not use the aromatics ordered in the present formula for percolation, but in place thereof added to the warm syrup a small quantity of the volatile oils, amounting for each pint to about a drop of oil of anise and of sassafras and about $\frac{1}{2}$ drop of oil of gaultheria. The syrup is of a dark-brown color, has an agreeable flavor, and leaves an acrid impression in the throat.

R. F. Fairthorne (1881) recommended the exhaustion of the powder without alcohol by what he termed "intermittent percolation," or alternate maceration and percolation. The material is macerated for a day with sufficient water only to obtain by percolation one-fourth of the total liquid needed, and this is repeated twice in the same manner; the drugs are now completely exhausted with cold water, the infusion concentrated by evaporation as much as necessary, and this liquid is added to the three portions previously obtained, which have in the mean time been mixed and kept in a cool place; the syrup is finally finished in the usual manner.

The syrup of the French Codex is made by hot infusion of sarsaparilla, borage-flowers, pale rose, senna, and anise; it is known as *sirap de Cuisinier*. Under the names of *sirap de Laffiteux* and *rob Boyveau-Laffiteux* a similar but more complex preparation has been in use in France; more than thirty drugs entered into its composition.

Medical Uses.—Compound syrup of sarsaparilla has been extensively used in the treatment of constitutional *syphilis*, but there is no evidence whatever to prove its efficiency when given alone. For this reason, probably, it is omitted from the British and German Pharmacopœias. It is a convenient vehicle for the administration of iodide of potassium. Corrosive sublimate, which is sometimes added to it, is converted by it into calomel. The *dose* is half a fluidounce (Gm. 16), diluted, several times a day.

SYRUPUS SCILLÆ, U. S., Br.—SYRUP OF SQUILL.

Syrupus aceti scillæ.—*Sirap de scille*, Fr.; *Meerzwiebelsyrup*, G.

Preparation.—Vinegar of Squill 40 parts (20 oz. av. or about $18\frac{1}{4}$ fluidounces); Sugar, in coarse powder, 60 parts (30 oz. av.); Water a sufficient quantity; to make 100 parts (50 oz. or about 36 fluidounces). Heat the vinegar of squill to the boiling-point in a glass or porcelain vessel, and filter while hot, adding, through the filter, enough

water to make the filtrate weigh 40 parts (20 oz. av.). Add the sugar, dissolve it by agitation without heat, and strain.—*U. S.*

The formula now directs the removal of the albumen in the manner suggested in the preceding editions of this work, and a permanently clear syrup is thus obtained. The sugar may be dissolved with the aid of heat, but percolation is to be preferred. The use of metallic vessels should be avoided. The syrup of the Br. P. is much denser than the above; it is made from an Imperial pint (20 fluidounces) of the vinegar and 40 oz. av. of sugar, and has a specific gravity of about 1.345.

Medical Uses.—This syrup is an adequate representative of squill—at least in its action upon the bronchial mucous membrane. It is much used in the treatment of laryngeal and bronchial *catarrhs*, both for promoting the resolution of such affections, and in children, when used in appropriate doses, for producing emesis, and thereby expelling accumulated secretions from the air-passages. It is habitually associated with syrup of ipecacuanha or syrup of senega, according to the nature of the case. The *dose*, as an expectorant, is from half a fluidrachm to a drachm (Gm. 2–4), and in the latter quantity it is emetic when repeated at short intervals.

SYRUPUS SCILLÆ COMPOSITUS, *U. S.*—COMPOUND SYRUP OF SQUILL.

Sirope de scille composé, Fr.; Zusammengesetzter Meerzwiebel-syrup, G.

Preparation.—Squill, in No. 30 powder, 120 parts (4 oz. av.); Senega, in No. 30 powder, 120 parts (4 oz. av.); Tartrate of Antimony and Potassium 3 parts (44 grains); Sugar, in coarse powder, 1200 parts (40 oz. av.); Precipitated Phosphate of Calcium 9 parts (130 grains); Diluted Alcohol, Water, each a sufficient quantity; to make 2000 parts (66⅔ oz. av. or about 3 pints). Mix the squill and senega, and, having moistened the mixture with 300 parts (10 oz. av. or 10⅓ fluidounces) of diluted alcohol, macerate for 1 hour; then transfer the mixture to a conical percolator, and gradually pour upon it diluted alcohol until 900 parts (30 oz. av. or about 30 fluidounces) of tincture are obtained. Boil this portion for a few minutes, and then evaporate it, by means of a water-bath, to 360 parts (12 oz. av. or about 11 fluidounces); having added 50 parts (5 oz. av. or 4⅓ fluidounces) of boiling water, triturate the mixture with the precipitated phosphate of calcium; filter, and add, through the filter, enough warm water to make the whole weigh 750 parts (25 oz. av. or about 24 fluidounces). In this dissolve the sugar by agitation, without heat, and strain. Lastly, dissolve the tartrate of antimony and potassium in 47 parts (1½ fluidounces) of hot water, and mix the solution thoroughly with the remainder of the syrup.—*U. S.*

The present formula is nearly identical with that of the *U. S. P.* 1870, and differs mainly in the removal of the pectin compounds by the aid of an inert powder (as we suggested in the former edition of this work) and in dissolving the sugar without heat. Percolation with diluted alcohol exhausts squill and senega thoroughly. The boiling of the tincture is probably intended to remove any albumen which may have been taken up. After the evaporation of the alcohol the pectin compounds of the senega are sometimes separated in considerable quantity, so as to impede filtration. On the addition of a little alkali, or after trituration with magnesia, filtration proceeds more rapidly; but the alkali, if dissolved in sufficient quantity, will then cause a decomposition of the tartar emetic. Trituration with some inert and insoluble substance, like calcium phosphate, before filtration is therefore preferable. The tartar emetic is best dissolved in a small quantity of boiling water before it is mixed with the syrup. When carefully prepared the syrup will keep well. It has been stated that by dissolving the sugar in the cold filtrate fermentation is entirely prevented; the solution of the sugar is readily effected by percolation.

This syrup is known as *hive syrup* and *croup syrup*, and is an official substitute for *Coccc's hive syrup*, which was made by boiling the drugs in water and preserving the liquid by honey.

Medical Uses.—The union of squill, senega, and tartar emetic in this preparation renders it expectorant, diaphoretic, emetic, and, in full doses, purgative also. It was originally devised for the treatment of “croup,” or “hives,” whence its popular name, “hive syrup.” It is not appropriate, however, for membranous croup, but only for the affection which is properly called *spasmodic laryngitis*, and which it relieves mainly by its nauseant, and therefore anti-spasmodic, action. Care must be taken in employing it not to allow its sedative operation to proceed too far. It may be prescribed in this affection in *doses* of from 10 to 30 drops (Gm. 0.60–2), repeated at intervals of ten minutes or until

its nauseant or emetic operation is developed. In acute *bronchitis* with adequate secretion it should be administered in similar doses, but at longer intervals, so as to keep within the limits both of nausea and vomiting.

SYRUPUS SENEGÆ, U. S., P. G.—SYRUP OF SENEGA.

Sirop de polygala, Fr.; *Senegasyrup*, G.

Preparation.—Fluid Extract of Senega 160 parts (8 oz. av.); Water of Ammonia 4 parts (87½ grains or 1½ fluidrachms); Sugar, in coarse powder, 600 parts (30 oz. av.); Water, a sufficient quantity; to make 1000 parts (50 oz. av. or about 36 fluidounces). Mix the fluid extract with 250 parts (12½ oz. av. or 12 fluidounces) of water; add the water of ammonia, shake the mixture well, and let it stand for a few hours; then filter through paper, adding through the filter enough water to make the whole weigh 400 parts (20 oz. av. or about 18 fluidounces). To the filtered solution add the sugar, dissolve it by agitation without heat, and strain.—*U. S.*

As formerly prepared from a tincture of senega, the separation of pectin compounds occasioned difficulty in filtration, which is now avoided by keeping the gelatinous matters in solution by the aid of ammonia, a portion of which is already contained in the pharmacopœial fluid extract. The syrup has a brown color and a decidedly acrid taste; it should be free from ammoniacal odor. 100 parts of syrup contain about 16 (*U. S.*), 4 (*P. G.*), or 2.5 (*F. Cod.*) parts, of senega.

Medical Uses.—The syrup of senega is a very useful medicine in subacute and chronic *bronchitis* and *laryngitis* in the dose of 1 or 2 fluidrachms (Gm. 4–8).

SYRUPUS SENNÆ, U. S., Br., P. G.—SYRUP OF SENNA.

Sirop de séné, Fr.; *Sennasyrup*, G.

Preparation.—Senna, bruised, 33 parts (16½ oz. av.); Sugar, in coarse powder, 60 parts (30 oz. av.); Alcohol 4 parts (2 oz. av. or 18½ fluidrachms); Oil of Coriander (8½ grains or 10 minims), Water, each a sufficient quantity; to make 100 parts (50 oz. av. or about 36 fluidounces). Digest the senna in 160 parts (5 lbs. av. or 4¾ pints) of water, at a temperature not exceeding 50° C. (122° F.), for 24 hours; express and strain the liquid. Digest the mass with 70 parts (35 oz. av. or 33¾ fluidounces) of water at the same temperature for 6 hours, and again express and strain. Mix the strained liquids and evaporate the mixture to 30 parts (15 oz. av. or about 14 fluidounces). When cold add the alcohol, previously mixed with 1 per cent. of oil of coriander, and filter through paper, adding through the filter enough water to make the whole weigh 40 parts (20 oz. av. or about 18 fluidounces). Then add the sugar, dissolve it by agitation without heat, and strain.—*U. S.*

This formula is modelled after that of the British Pharmacopœia; by a similar process 16 oz. av. of senna are made to yield 16 fluidounces of concentrated and filtered infusion, including 3 fluidounces of rectified spirit and 3 minims of oil of coriander, and in this liquid 24 ounces of sugar are dissolved. This syrup weighs 42 ounces, and its specific gravity is about 1.310.

Senna Syrup, *P. G.*, is only about one-fourth the strength of that of the *U. S. P.*, and is flavored with fennel.

SYRUPUS SENNÆ CUM MANNA, *P. G.*, is made by mixing equal parts of syrup of senna and syrup of manna (see p. 958).

Medical Uses.—This is a mild and efficient cathartic for children in the dose of from 1 to 4 fluidrachms (Gm. 4–16).

SYRUPUS TOLUTANUS, U. S., Br.—SYRUP OF TOLU.

Syrop de baume de Tolu, *Sirop balsamique*, Fr.; *Tolubalsamsyrup*, G.

Preparation.—Balsam of Tolu 4 parts (2 oz. av.); Sugar, in coarse powder, 65 parts (32½ oz. av.); Distilled Water a sufficient quantity; to make 100 parts (50 oz. av. or about 36 fluidounces). Mix the sugar with 35 parts (17½ oz. av. or 16¾ fluidounces) of distilled water, add the balsam, and digest the whole in a covered vessel, at a temperature not exceeding 82° C. (180° F.), for 2 hours. When cold strain through a well-wetted muslin strainer, adding through the strainer enough water to make the syrup weigh 100 parts (50 oz. av.), and mix thoroughly.—*U. S.*

Take of balsam of Tolu 1½ ounces; refined sugar 2 pounds; distilled water 1 pint or

a sufficiency. Boil the balsam in the water for half an hour in a lightly-covered vessel, stirring occasionally. Then remove from the fire, and add distilled water, if necessary, so that the liquid shall measure 16 ounces. Filter the solution when cold, add the sugar, and dissolve with the aid of a steam or water-bath. The product should weigh 3 pounds, and should have the specific gravity 1.33.—*Br.*

The formula of the U. S. P. 1870 was objectionable on account of the use of magnesium carbonate for diffusing tincture of Tolu previous to treating it with water; the present formula yields a turbid syrup which cannot be obtained transparent by straining. The objection to the second formula is in the boiling, by which the toluene is volatilized. Digesting the Tolu balsam with water, as directed by the French Codex, is preferable, and yields a well-flavored, transparent syrup of a yellowish color. Using tincture of Tolu and manipulating as directed for syrup of ginger, an efficient but somewhat opaque syrup is obtained. The syrup is used in preparing Trochisci ammonii chlor. and Trochisci cubebæ, *U. S.*

SYRUPUS BALSAMI PERUVIANI, *S.* SYRUPUS BALSAMICUS. Digest 1 part of balsam of Peru in 11 parts of water; decant and filter when cold, and dissolve 18 parts of sugar in 10 parts of the filtrate.—*P. G.* 1872.

Medical Uses.—The medicinal virtues of this preparation are exceedingly feeble, if indeed it possess any. But its agreeable flavor renders it an eligible associate of other and less palatable syrups, especially such as are used in bronchial catarrhs. *Dose*, a fluidrachm (*Gm.* 4).

SYRUPUS ZINGIBERIS, *U. S., Br.*—SYRUP OF GINGER.

Sirap de gingembre, *Fr.*; *Ingwersyrup*, *G.*

Preparation.—Fluid Extract of Ginger 2 parts (1 oz. av.); Sugar, in coarse powder, 65 parts (32½ oz. av.); Water a sufficient quantity; to make 100 parts (50 oz. av. or about 36 fluidounces). Rub the fluid extract of ginger with 25 parts (12½ oz. av.) of sugar, and expose the mixture to a heat not exceeding 50° C. (140° F.) until all the alcohol has evaporated. Then mix the residue thoroughly, by agitation, with 35 parts (17½ oz. av. or 16¼ fluidounces) of water, and filter the liquid, adding through the filter enough water to make the whole weigh 60 parts (30 oz. av.). Finally, add the remainder of the sugar, dissolve it by agitation without heat, and strain.—*U. S.*

This formula accords with the suggestions made in previous editions of this work, and yields a syrup which, though not perfectly transparent, is not opaque, and contains the volatile oil as well as the pungent resin of ginger. In order to obtain a syrup of handsome appearance, the fluid extract must be well incorporated with, not merely poured upon, the sugar. The former Pharmacopœia used magnesium carbonate for diffusing the fluid extract preceding the treatment with water; a syrup was thus obtained which was transparent and had the odor of ginger, but contained magnesia in solution, and had but little pungency. The syrup of the *Br. P.* is milky; it is made by mixing strong tincture of ginger 6 fluidrachms with syrup 19 fluidounces.

Off. Prep.—Trochisci zingiberis, *U. S.*

Medical Uses.—It is chiefly employed as a flavoring ingredient of mixtures, but is most suitable as an addition to those which are intended to relieve *colic* by causing an expulsion of flatus. *Dose*, a fluidrachm or more (*Gm.* 4).

TABACUM, *U. S.*—TOBACCO.

Tubaci folia, *Fr.*; *Folia nicotianæ*, *P. G.*—*Leaf tobacco*, *E.*; *Nicotiane*, *Tubac*, *Fr.*; *Tabaksblätter*, *G.*

The commerciale dried leaves of *Nicotiana Tabacum*, *Linné*. *Steph.* and *Church*, *Med. Bot.*, plate 37; *Bentley* and *Trimen*, *Med. Plants*, 191.

Nat. Ord.—*Solanaceæ*.

Origin.—The tobacco-plant is indigenous to tropical America, but the country which originally produced it cannot now be ascertained, since tobacco is now unknown in the wild state. The seeds were sent to Spain in 1518 by Fra Romano Pane, and reached France in 1560 from Lisbon through the French ambassador, Jean Nicot. The cultivation of tobacco was commenced in Holland in 1615, soon afterward in England, and about fifty years later in the Palatinate. About the same period, or a little earlier, it appears to have been introduced into China. At present tobacco is very extensively cultivated in most temperate and subtropical countries. During 1875 there were over 559,000

acres of land planted in the United States, yielding 367,000,000 pounds of tobacco. The annual production of tobacco in all countries has been estimated at about 3,000,000 tons.

N. TABACUM attains a height of 4 or 6 feet (1.2–1.8 M.), has a stout, viscidly hairy stem, shortly-stalked or sessile amplexicaul and alternate leaves, and terminal panicles of dull-pink or reddish flowers consisting of a tubular, bell-shaped, five-toothed calyx, a funnel-shaped corolla about 2 inches (5 Cm.) long, with a spreading five-lobed border and five stamens and a conical ovary. The capsule is about an inch (25 Mm.) long, opens by two valves, is two-celled, and contains a large number of minute, somewhat reniform, pale-brown seeds. *Nicotiana macrophylla*, *Lehmann*, *Nic. fruticosa*, *Liné*, *Nic. petiolata*, *Agardh*, and others are now regarded as varieties of the above species.

Nic. repanda, *Willdenow*, is cultivated in Cuba; *Nic. persica*, *Linley*, yields the Shiraz or Persian tobacco; and *Nic. rustica*, *Liné*, is the species which is chiefly cultivated in Turkey and India. The last-named species is about 4 feet (1.2 M.) high, has oval or ovate entire leaves on petioles about 1½ inches (38 Mm.) long, and produces greenish-yellow flowers nearly an inch (25 Mm.) long. According to Thiselton Dyer, Latakia tobacco is prepared from the flowering panicles and capsules of *N. Tabacum*, and owes its peculiar flavor to the smoke of the wood of *Pinus halepensis*, *Aiton*, to which it is exposed.

Cultivation.—The plant requires a deep, rich soil, which must be annually well manured; the seeds are sown in beds, and when the young plants are 6 or 8 inches high they are transplanted to the tobacco-fields, and during their growth carefully freed from the larvæ of insects. The flowering tops and branches are broken off before the flowers expand, and when the leaves are fully matured, which takes place about the month of September, the plants are cut, allowed to wilt in the sun, and afterward cured by being hung up in a drying-house and exposed to the heat of a fire. The leaves at first become wet, or "sweat," and in the course of several weeks are dried, after which they are stripped from the stems, assorted, gathered up into small parcels, and then are packed into large boxes or hogsheads.

Description.—Tobacco-leaves are from 6 to 20 inches (15–50 Cm.) long and from 2 to 6 inches (5–15 Cm.) wide, oval or ovate-lanceolate, sometimes rather obovate in form, pointed and acute at the apex, and with an entire margin. In the fresh state they are rather thick, green, and covered with viscid hairs and with small sessile glands; after drying they are thinner, lighter or darker brown or mottled with different shades of brown, and friable. The leaves have a thick, prominent midrib, branching under acute angles into lateral veins, which are curved near the margin. The odor of tobacco is peculiar and heavy, and its taste disagreeable, bitter, and acrid.

Constituents.—Tobacco contains a large amount of salts, consisting of sulphates, nitrates, chlorides, phosphates, and malates of potassium, calcium, ammonium, and nicotine, and yields from 14 to 18.5 per cent. of ash. Larger amounts have been obtained, sometimes as much as 25 to 27 per cent.—a result which is probably due in some cases to dust adhering to the viscid glands, as was suggested by B. F. Creighton (1876). The other constituents of tobacco are albumen, resin, extractive, gum, citric acid (Goupil), nicotianin, and nicotine. *Nicotianin* was discovered by Hermstädt on distilling tobacco with water; it separates from the distillate in the form of white foliaceous crystals, which have an odor resembling that of tobacco-smoke and a warm and bitterish aromatic taste (Posselt and Reimann, 1828). Landerer (1835) obtained nicotianin from the dried, but not from the fresh leaves. Barral (1845) stated that it contains 7.12 per cent. of nitrogen.

Nicotine or *nicotia* is the poisonous principle of tobacco, and was discovered by Posselt and Reimann (1828). It may be prepared by exhausting bruised tobacco with acidulated water, concentrating the infusion, adding an excess of potassa, and agitating with ether, which dissolves the alkaloid, and on the addition of powdered oxalic acid nicotine oxalate, which is insoluble in ether, is separated (Schloesing); or, the ether is evaporated, the liquid neutralized with oxalic acid, evaporated to dryness, and the residue exhausted with boiling alcohol, which dissolves oxalate of nicotine (Ortígoza). On evaporating the solution to a syrupy consistence and agitating it with potassa and ether, an ethereal liquid is obtained, which on fractional distillation yields the alkaloid. This is a colorless oily liquid, having at 15° C. (59° F.) the spec. grav. 1.0111, and remaining liquid at –10° C. (14° F.). It has an unpleasant, and when heated a pungent, acrid, tobacco-like odor, a burning taste, and a strongly alkaline reaction. Exposed to air and light, it rapidly acquires a brown color and is partly converted into a resinous compound. It boils near 250° C. (482° F.), but distils at a lower temperature, always leaving a residue.

Its composition is $C_{10}H_{14}N_2$ (mol. weight 162). It absorbs water from the air, dissolves readily in water, and is separated from this solution by caustic potassa. Alcohol and ether dissolve it in all proportions, and it yields with acids neutral and acid salts, of which the former crystallize with difficulty, and are mostly soluble in weak alcohol, but insoluble in ether. The alkaloid acquires a wine-red color with strong sulphuric acid, and on heating the mixture is charred. Chlorine gas colors it deep-red or red-brown. When heated with a little hydrochloric acid a violet color is produced, which on the further addition of nitric acid changes to yellowish-red. The double salts with mercuric and platinum chloride are sparingly soluble in cold water. Dried tobacco-leaves contain from 2 to 8, and occasionally as high as 11, per cent. of nicotine. The alkaloid is present in all parts of the green plant, as well as in the dried leaves, and, according to Kissling (1882), also in tobacco-smoke, which owes its toxic action mainly to this alkaloid. Instead of nicotine, H. Vohl and H. Eulenburg (1871), found chiefly *collodine*, with *pyridine*, *picoline*, and other bases of the same series (see page 1046), besides ammonia and traces of ethylamine; and, in passing the vapors through potassa solution, hydrocyanic, hydrosulphuric, acetic, formic, butyric, valerianic, carbolic, and probably other acids were retained.

Pharmaceutical Products.—**OLEUM TABACI**, Oil of tobacco (*U. S.* 1870), is prepared by dry distillation of coarsely-powdered tobacco, and is a brown-black tar-like liquid of a strong and very peculiar empyreumatic odor. Unverdorben (1826) recognized in it the presence of an alkaloid, which on being boiled with diluted sulphuric acid yields, among other products, *odorine* or *picoline*: it is not unlikely that others of the ternary bases contained in animal oil (see page 1046) may likewise be present in this tarry product. Zeise (1843) demonstrated the presence of butyric acid, ammonia, paraffin, empyreumatic resin, and a pale-yellow oil of the formula $C_{11}H_{22}O_2$, which boils at $195^{\circ} C.$ ($383^{\circ} F.$). Melsens (1843) proved the presence of nicotine in the tarry matter separating in tobacco-pipes, and it is most likely present in the empyreumatic oil.

UNGUENTUM TABACI, Tobacco ointment (*U. S.* 1870). The aqueous extract from $\frac{1}{2}$ oz. av. of powdered tobacco is mixed with 8 oz. av. of lard.

VINUM TABACI, Wine of tobacco (*U. S.* 1870). Exhaust 120 grains of tobacco with 4 fluid-ounces of sherry wine.

Off. Prep.—Enema tabaci, *Br.*

History.—The use of tobacco by smoking cigars was practised by the natives of Cuba when that island was discovered in 1492, and pipe-smoking was then probably common among the aborigines of this continent, since it was observed in Canada in 1585 and in Florida in the seventeenth century. It was introduced into England in 1586. From these beginnings the use of tobacco spread over the whole world. In several countries of Europe the imposts upon it furnish the largest item of the national revenue, and it is there, as in this country, one of the most important articles of commerce.

Physiological Action.—*On Plants and Animals:* Tobacco is hostile to all forms of life. Plants confined in rooms where the fermentation of tobacco is conducted during the manufacture of snuff soon lose their foliage, and nearly all insects shun tobacco, whence its use to protect woollen fabrics from moths, etc. Herbivorous animals are not readily affected by it, but large doses even by the stomach are fatal to them. When its fumes are thrown into the lungs of animals or when its decoction is applied to their skin, its poisonous operation is speedily developed. In animals poisoned by the so-called "oil of tobacco" the blood is uncoagulated. From 2 to 5 grains of it given to dogs two or three times a day produced gradual but complete marasmus, partial paralysis of the hind legs, loss of venereal power with softening and shrivelling of the testicles, shedding of the hair, sloughing of the eyelids, and blindness. The gums were swollen, spongy, and bleeding, and the teeth became loose. The oil of tobacco, in the form in which it accumulates in the bowl of smoking-pipes, is a virulent poison even when applied to eruptions upon the skin. Its immediate effects are pallor, vertigo, faintness, nausea, vomiting, cold sweating, diarrhoea, and paralysis of the lower limbs. It is remarkable that there appears to be no fatal case of poisoning by this oil on record, except that of a child in whom the oil from a tobacco-pipe was applied to an ulcer on the lip.

Nicotine acts poisonously upon all animals. In horses its most striking influence is upon the pulse, which becomes less frequent, and continues to be so for many hours. In dogs it is fatal by arresting, after reducing, the action of the heart, and occasioning faintness, trembling, and vomiting. It neither irritates nor cauterizes the skin or the mucous membrane. In small doses it quickens, and in large doses checks, respiration, which is also accompanied by a hissing sound, attributed to a spasm of the laryngeal and bronchial muscles. It also retards and depresses the pulse when given in full doses. In frogs and snakes among its poisonous effects tetanic spasm is conspicuous, and in warm-blooded ani-

mals generally it excites alternate tonic and clonic spasms, followed by general relaxation and trembling. It has been shown by Lautenbach (*Phila. Med. Times*, x, 523) that nicotine acts with extreme rapidity and violence when thrown into the systemic veins, but very slowly, by comparison, and feebly, when injected into the arterial or the portal system. According to René, nicotine suspends the galvanic contractility of muscles, and causes a fibrillar trembling of these organs before it induces distinct spasms (*Amer. Jour. of Med. Sci.*, July, 1879, p. 247). The motor paralysis appears to affect the hinder legs chiefly. When the dose is very large its direct and immediate effects are extreme prostration and death. In some cases it appears to act as an anæsthetic, and in others to occasion pain. Primarily it dilates the pupil, but secondarily may contract it. Sometimes salivation and diuresis are abundant, and in non-lethal doses it is apt to cause vomiting and purging. From these statements it may be inferred that nicotine depresses the heart, quickens the respiration, and excites the muscular system, but its ultimate effect is general exhaustion.

After the death of animals by nicotine "the brain is empty of blood; the stomach is reddened in round spots, so raised and pile-like that they resemble patches of dark Utrecht velvet; the blood is preternaturally fluid; the lungs are pale as the lungs of a calf as we see them suspended in the shambles; while the heart is overburdened with blood, and, having little power left for its forcing action, is scarcely contracting, but is feebly trembling, as if, like a conscious thing, it knew equally its own responsibility and its own weakness" (Richardson).

On Man: The essential effects of tobacco are best illustrated by the action of nicotine employed experimentally. The following summary represents the effects of doses of nicotine varying from $\frac{1}{32}$ to $\frac{1}{16}$ grain, taken in water. The minutest doses occasion a burning sensation in the tongue, a hot, acrid feeling in the fauces, and a sense of rawness throughout the œsophagus. Salivation is abundant. Small doses produce a sense of heat in the stomach, chest, and head, and even in the fingers, with some excitement of the nervous system; larger ones cause heaviness, giddiness, torpor, sleepiness, indistinct vision, with sensitiveness of the eye to light, imperfect hearing, laborious and oppressed breathing, and dryness of the throat. In 40 minutes after the larger doses a sense of great debility is perceived, the head droops, the pulse-rate falls, the face grows pale, the features are relaxed, the limbs seem paralyzed, the hands and feet are cold, the coldness advances gradually toward the trunk, and faintness ends in loss of consciousness. The disorder of the digestive organs manifests itself by eructations, nausea, and even vomiting, the abdomen becomes distended, and an urgent desire is felt to go to stool; wind is discharged and urine voided copiously. The nervous system, after the debilitating influence of the poison has developed itself, shows its condition by muscular spasm, which begins with tremulousness of the extremities, and gradually involves the whole muscular system, including the respiratory muscles, so that the breathing is oppressed, gasping, and incomplete. This enumeration of effects is sufficient to prove that nicotine acts primarily upon the spinal and sympathetic nervous systems, and not upon the brain. It may cause death by direct paralysis of the heart, or more indirectly by paralysis of the respiratory muscles, producing asphyxia. The blood examined during life of a person under the full influence of tobacco presents a striking disaggregation of the red corpuscles, which are also less regularly circular than natural, and have jagged or crenated edges. As the poisonous operation passes off, however, the blood regains its normal characters. The action of tobacco itself is so nearly identical with that of nicotine as to render unnecessary a detailed account of it in this place. It, however, is mainly exhibited in muscular relaxation and collapse. In some cases "lethargy" and "insensibility" are mentioned, but the condition is not that of cerebral oppression so much as of cerebral exhaustion. Of other symptoms especially prominent in certain cases of tobacco-poisoning, either caused by a single excessive dose or by inordinate indulgence in smoking or chewing tobacco, may be mentioned: a rapid followed by a very slow pulse, hiccough, and cold perspiration, profuse diuresis, convulsions without loss of consciousness, sometimes cataleptic and sometimes hysterical, and great numbness as well as impaired motor power of the limbs and of the tongue (*e. g.* case in *Amer. Jour. of Med. Sci.*, Jan. 1882, p. 306).

The cases of serious illness produced by the emanations of tobacco, and by its application even to the unbroken skin, are innumerable, and many instances of fatal poisoning by tobacco are recorded, some of them being due to its having been swallowed purposely or accidentally, some to its use medicinally in an enema, and some to its application to eruptions on the skin. The fatal dose of tobacco internally, and generally by enema, has varied from the maximum of an ounce or two to a minimum of 15 grains. It was

generally administered in decoction or infusion. Nicotine stands next to prussic acid in the rapidity and energy of its poisonous action, but the minimum fatal dose of it is unknown.

A detailed account of the evil effects of the habitually excessive use of tobacco by smoking, snuffing, or chewing would occupy more space than can be spared for the purpose in this work, but a condensed statement of the principal ones may not be omitted. (For full details see STILLÉ, *Therapeutics*, 4th ed., ii. 364 et seq.) It lessens the natural appetite, more or less impairs digestion, and induces constipation, while it irritates the mouth and throat, rendering it habitually congested and impairing the purity of the voice. It induces a constant sense of uneasiness and nervousness, with epigastric sinking or tension, palpitation ("irritable heart"), hypochondriasis, impaired memory, neuralgia, and frequent urination. Chewing and snuffing tend to cause gastralgia, but smoking causes neuralgia of the fifth pair. It renders the vision weak and uncertain, causing objects to appear nebulous, or creates *muscæ volitantes* and similar subjective perceptions. In numerous instances it is said to have produced amaurosis. But others decline to describe the effect by that word, employing rather "scotoma," or simple obscurity or indistinctness of vision. It usually disappears soon after the use of tobacco is abandoned (Nettleship, *St. Thomas's Hosp. Rep.*, ix. 51). Analogous derangements of hearing occur, with buzzing, ringing, etc. in the ears, and even hallucinations of this sense. Often there is a feeling of a rush of blood to the head, with vertigo and impairment of attention, so as to prevent continuous mental effort; the mind is also apt to be filled with crude and groundless fancies, leading to self-distrust and melancholy. The sleep is frequently restless and disturbed by distressing dreams. It impairs muscular power and co-ordination, probably both by interfering with nutrition and by exhausting nervous force, and usually keeps down the growth of muscle and the deposit of fat. Doubtless there are many persons who use tobacco in one or more forms who experience few or none of these evils, and whose constitutions seem proof against its mischievous effects; but to the greater number the habitual use of it is more injurious than useful, and it acts upon a certain number in almost all doses as a poison. Its poisonous action upon children and lads is far more intense and prolonged than upon adults.

Medical Uses.—Although the use of tobacco as an external remedy is no longer common, its efficacy is sufficiently well established in several diseases. It has been applied to the treatment of *scabies* in man, and long was used, and perhaps still is, for the same disease in domestic animals, but the risk of producing toxicol symptoms when the skin is broken has probably led to its disuse. The same remark applies to other cutaneous eruptions. The bruised fresh leaves of the tobacco-plant have been found a local palliative in *urticaria*, *gout*, and *rheumatism*, and the fumes of tobacco have been applied with advantage in the last two disorders. Snuffing has been employed with success in the cure of *nasal polypus*, for the relief of chronic *ophthalmia* and catarrh of the *frontal sinuses*, and in tropical countries for destroying the *worms* which sometimes breed in the antrum highmorianum and the adjacent parts.

Internally, the smoke of tobacco inhaled is a palliative of nervous *cough* produced by tickling in the larynx or trachea, and has put an end to an attack of *spasmodic laryngitis* in the same manner as other nauseants and cardiac sedatives. A plaster made with strong snuff and tallow is a popular remedy in the same disorder, and has been applied successfully in *laryngismus stridulus*. Obstinate *hicough* has been arrested by swallowing tobacco-smoke, and *dislocations* of the lower jaw and of various joints have been remedied while the patient was relaxed by tobacco-fumes.

The relaxing, nauseating, and purgative operation of tobacco has been successfully employed to overcome *obstruction of the bowel* by fecal accumulations. When the usual purgative agents have failed, tobacco cataplasms or enemas may be cautiously employed. It is not certain that *internal herniæ* and *intussusception* have not been relieved by this treatment, but the accurate diagnosis of intestinal obstructions is very difficult, and care must be taken not to exhaust the patient by heroic measures while a reasonable hope remains that nature will suffice for the cure. It is quite erroneous to suppose that these intestinal obstructions are overcome by relaxing muscular spasm; the only rational explanation of the utility of tobacco, and of various other medicines of the same class, is that by lowering the heart's action they tend to diminish the vascular congestion of the strangulated organ. In *lead colic*, in which tonic spasm probably does exist, tobacco may act as a true anti-spasmodic, but in this affection it is seldom used.

The powerful relaxing influence of tobacco led naturally to its use in the treatment of

tetanus, and the list is long of the cases in which its infusion was given by enema. More recently nicotine was administered in this disease by the mouth or the rectum. It is, as might be expected, a surer remedy in the idiopathic than in the traumatic form of the disease. Tobacco has generally been prescribed in tetanus in an infusion made with 20 grains of the drug to $\frac{1}{2}$ pint of water (Gm. 1.30 in Gm. 250), and nicotine in the dose of a fraction of a drop, increased until its specific effects are developed. The same means as in tetanus have been employed in several cases of *strychnine-poisoning*. The power of tobacco-smoke to arrest or palliate paroxysms of *asthma* is well established. There is reason to believe that it is quite as efficient as lobelia, with which it is almost identical in operation. *Ascarides* of the rectum, and even *lumbricoid* worms, have been expelled after the injection into the rectum of tobacco-smoke or of tobacco infusion. This substance is alleged to be an antidote to poisoning by *mushrooms*, but upon insufficient grounds.

Administration.—Tobacco may be given as an emetic in the dose of 5 or 6 grains (Gm. 0.30), but it is rarely prescribed in this form. The infusion, wine, and ointment are no longer official. Fresh tobacco-leaves, which are sometimes used as a topical application, are much feebler in their action than the cured leaves, and those especially which have undergone fermentation in their manufacture. The dose of nicotine may be stated at from $\frac{1}{6}$ grain to 1 grain (Gm. 0.01–0.06), but some authorities recommend that the primary dose should not exceed $\frac{1}{60}$ grain (Gm. 0.001). For hypodermic injection a solution has been proposed containing the quantity of nicotine just mentioned in every 5 drops (Gm. 0.30). Of this solution the primary dose should not exceed the $\frac{1}{120}$ grain (Gm. 0.0005). Nicotine should never be used internally if either of the other preparations of tobacco can be procured.

TAMARINDUS, U. S., Br.—TAMARIND.

Pulpa tamarindorum cruda, s. *Fructus tamarindorum*, P. G.—*Tamarin*, *Pulpe de tamarin*, Fr.; *Tamarindenmus*, G.

The preserved fruit of *Tamarindus indica*, Linné, s. *T. officinalis*, Hooker. Woodville. *Med. Bot.*, pl. 166; Bentley and Trimen, *Med. Plants*, 92.

Nat. Ord.—Leguminosæ, Cæsalpinieæ.

Origin.—The tamarind tree attains a height of 60 to 80 feet (18–24 M.), is indigen-

ous to India and throughout tropical Africa, and has been introduced into all tropical countries. It has alternate abruptly pinnate evergreen leaves, with from ten to eighteen pairs of oval-oblong, at the base unequal, veined leaflets, and produces few-flowered terminal and lateral racemes. The fragrant flowers have a four-lobed calyx, the upper lobe being broad and two-toothed; the corolla is white, afterward yellow, red-veined, and consists of three elliptical petals, which are longer than the calyx; occasionally two more petals, linear and minute, are present; the nine or ten stamens are monadelphous, but only three or four have anthers; the ovary is stalked and has a long style. The fruit is an indehiscent usually curved legume, about 6 inches (15 Cem.) long and nearly 1 inch (25 Mm.) broad. The West Indian tree bears a fruit which is only about three times longer than broad, and was formerly regarded as a distinct species, *T. occidentalis*, Gaertner. The fruit has a thin, fragile, pale-brownish shell (pericarp), and

FIG. 294.

Tamarindus indica, Linné: flowering branch, pod, and pod with shell removed.

underneath this there are found on each side three tough fibrous somewhat branching veins running from the base to the apex. Next follows an acidulous pulp, and this adheres to a tough membrane which encloses from three to ten cavities, each of which contains a single flat somewhat quadrangular and polished brown seed.

Preparation.—Before tamarinds enter commerce the shell is removed, and the inner

portion is in India pressed together into a mass to which sometimes sugar is added. In Upper Egypt it is formed into cakes which are dried in the sun, and in the West Indies hot syrup is poured over the pulpy mass. The fresh leaves and flowers have an acidulous taste, and are used in tropical countries for the preparation of cooling drinks.

Description.—As seen in our commerce, tamarinds form a reddish-brown soft mass in which the interior portion of the fruit is more or less broken. They have a fruit-like odor and an acidulous and sweet taste. *East Indian tamarinds* are tougher and darker in color and have a less sweet taste. *Egyptian tamarinds* appear in hard, flattish, circular cakes, about 6 inches (15 Cm.) in diameter, of a brown-black color externally, and frequently mouldy. The last two varieties are rarely met with in American commerce. On leaving the clean blade of an iron spatula for some time in contact with tamarinds, it should not become covered with a coating of copper.

Constituents.—Vauquelin ascertained tamarinds to contain sugar, tartaric, citric, and a little malic acid, pectin, and mucilaginous matter. The acids are mostly present as potassium compounds. Acetic acid has likewise been found in tamarinds; it probably results from the fermentation of the sugar. Tannin is not present, except in the testa of the seeds. C. Mueller (1882) found in East Indian tamarinds very little malic acid; citric acid varied between 6 and 4 per cent., tartaric acid between 5.3 and 8.8 per cent., potassium bitartrate between 4.7 and 6 per cent., the insoluble matter of the pulp between 12 and 20 per cent., and the seeds between 1.5 and 38 (average 13.9) per cent.

Pharmaceutical Uses.—Tamarinds are employed in the preparation of *Confectio sennæ*, *U. S.*, *Br.*, being freed from vegetable tissues by means of water and straining.

PULPA TAMARINDORUM DEPURATA, P. G., is made by softening East Indian tamarinds with sufficient boiling water, straining the mass through a hair sieve, evaporating the strained portion to the consistence of an extract, and incorporating with 5 parts of it 1 part of powdered sugar.

CONSERVA TAMARINDI, F. Cod. Tamarind-pulp 2 parts; powdered sugar 5 parts, water sufficient for 8 parts.

TAMAR INDIEN is a confection of senna flavored with anise and oil of lemon.

Medical Action and Uses.—Tamarinds are mentioned by the Arabian medical writers as antibilious and useful in correcting nausea, quenching thirst, and allaying febrile excitement, and also as being efficient in healing aphthous sores. They are still used for similar purposes, and especially to prepare a cooling drink in *febrile diseases*. They should be mixed with hot water, and the strained liquid allowed to cool. An ounce of tamarind-pulp boiled with a pint of milk produces a whey which also forms an agreeable drink in fevers. Although reputed to impair the purgative action of senna, they are habitually used along with that cathartic in magistral preparations, as well as in the official confection of senna.

TANACETUM, U. S.—TANSY.

Summitates tanacetæ.—*Tanaisie, Herbe aux vers, Fr.*; *Rainfarn, Wurmkrout, G.*

The leaves and tops of *Tanacetum vulgare*, *Linneé*, s. *Chrysanthemum Tanacetum*, *Karsch.*

Nat. Ord.—*Compositæ, Senecionidæ.*

Origin and Description.—Tansy is a perennial herb indigenous to Europe and Central Asia and naturalized in many parts of North America, where it grows in old fields, along roadsides, and in the neighborhood of river-banks. The stout and fibrous many-headed root sends up a cluster of nearly simple stems which are 3 or 4 feet (.9–1.2 M.) high, roundish-angular, and frequently purplish at the base. The leaves are alternate, shortly petiolate or sessile, from 5 to 10 inches (12–25 Cm.) long and nearly half as wide, smooth, dark-green, dotted with oil-glands, bipinnately divided, and the segments rounded, incised, or coarsely serrate. The flowers are in a dense terminal corymb, have an imbricate involucre with numerous brown-margined scales, a convex naked receptacle, and numerous yellow florets, with the marginal ones pistillate and three-toothed, but not ligulate. The akenes are obovate, about five-ribbed, and terminate with a crown-like pappus. The plant commences to bloom in July, and should be collected while flowering; on drying the loss in weight is from 80 to 85 per cent. It has a strong, rather unpleasant odor, and an aromatic, pungent, and bitter taste. A variety, *Tan. crispum*, with twice-pinnatifid and curled leaves, is frequently cultivated, and is known as *double tansy*.

Constituents.—Among the ordinary constituents of tansy, *Peschier* and *Frommherz* found mucilage, sugar, albumen, fixed oil, resin, tannin, coloring matter, and malic

acid, with which Peschier's *tanacetie acid* is probably identical. The bitter principle was isolated by Leroy (1845) by a process similar to that for digitalin. This *tanactin* is described as being yellowish-white, granular, inodorous, fusible, soluble in ether, less freely soluble in alcohol, and sparingly soluble in water. Leppig (1882) gives for it the formula $C_{11}H_{16}O_4$, and found it to be present chiefly in the flowers; sulphuric acid colors it yellow, then brown, red-brown, and blood-red, the margin becoming blue. The most important constituent of tansy is its volatile oil, of which the fresh flowering herb yields $\frac{1}{4}$ to $\frac{1}{2}$ per cent. of its weight. *Oil of tansy*, *Oleum tanacetii*, is an oxygenated oil of neutral or slightly acid reaction, varies in density between 0.92 and 0.95, and has either a yellow or green color. According to Geoffroy, the herb grown in dry places yields a green-colored volatile oil, but if grown in moist localities the oil is yellow. Oil of tansy has a camphoraceous aromatic odor and a bitterish pungent taste, deviates polarized light to the left, is readily soluble in alcohol, dissolves iodine without explosive action, and is readily oxidized on being heated with nitric acid. Bruylants (1877) found in it 1 per cent. of a terpene, $C_{10}H_{16}$, boiling near 160° C. (320° F.), and a small quantity of an acid and a neutral resin, while the greater portion consists of the aldehyd, $C_{10}H_{16}O$, mixed with about 20 per cent. of the alcohol, $C_{10}H_{18}O$.

Allied Plant.—*TANACETUM BALSAMITA*, *Linneé*, s. *Pyrethrum Tanacetum*, *De Caudolle*, *Balsamita suaveolens*, *Persoon*.—*Costmary*, *E.*: *Balsamite*, *Fr.*: *Frauenminze*, *G.*—This is a perennial herb of Southern Europe, with undivided serrate, oval-oblong, petiolate leaves, and discoid, yellow, hemispherical flower-heads in terminal corymbs. It has a strong aromatic odor and bitter taste, and is employed like tansy, and recognized as such by the French Codex.

Physiological Action.—*On Animals*: In some experiments 2 fluidrachms of oil of tansy given to a dog caused vomiting, salivation, dilated pupils, twitching of the muscles, followed by clonic convulsions and a cataleptic condition, from which the animal recovered. $\frac{1}{2}$ fluidounce produced the same symptoms, from which, however, recovery took place, and then, on the same dose being repeated, a prolonged and fatal convulsion occurred, death being apparently due to asphyxia from paralysis of the respiratory muscles. On examination after death, the veins of the brain and spinal marrow were highly congested and a serous effusion existed in the pia mater. The lungs were engorged, and the heart empty on its left side, but its right cavities were distended with dark and liquid blood. The kidneys were congested and the bladder contracted (Van de Warker).

On Man: The author of the above experiments found that 10 minims of the oil of tansy taken by himself caused a sense of heat in the stomach, extending throughout the abdomen, flushing and fulness of the face and head, giddiness, and diuresis, lasting for many hours, the urine smelling strongly of tansy. Subsequently, a dose of 15 minims of the oil, repeated after 3 hours, induced similar effects, but the head symptoms were more marked and unpleasant and the diuresis was very copious. The pulse grew more frequent and less full, and the temperature was slightly raised.

In excessive and poisonous doses oil of tansy causes a sense of heat or burning in the œsophagus, stomach, and abdomen, with dizziness, numbness, and apparent paralysis, attended or followed by clonic convulsions, flushing or lividity of the face, dilated pupils, stertor, frothing at the mouth, and vomiting; hurried or laborious respiration, sometimes with stertor; the skin is usually moist and warm, the pulse somewhat increased in frequency; in fatal cases death is caused by coma and asphyxia. In a case of fatal poisoning by a decoction of the herb death took place by paralysis of the muscles of deglutition, respiration, and voluntary motion. Instead of these nervous symptoms, an infusion of tansy caused vomiting, purging, severe abdominal pain, and death in collapse, without previous impairment of intelligence (*Phila. Med. Times*, xi, 346). In another case it was attended with convulsions, and followed the taking of a teaspoonful of oil of tansy in an hour and a quarter. In a fatal case following a dose of 11 drachms of oil of tansy no congestion of the brain was found, but the heart was full of black blood and the lungs were shrunken and crepitous. The stomach was not inflamed (Jewett, *Boston Med. and Surg. Jour.*, March, 1880, p. 327).

The fatal poisonous dose of oil of tansy is undetermined; very grave symptoms have been produced by $\frac{1}{2}$ fluidrachm (Gm. 2), and even by a dose of 15 or 20 drops (Gm. 1-1.30).

Medical Uses.—Tansy was used in the Middle Ages and subsequently as a remedy for *amenorrhœa*, *worms*, and *dropsy*, and, although it is no longer regarded as of equal potency with other medicines in these diseases, its efficacy cannot be reasonably questioned. Its tonic and stimulant virtues resemble those of absinth, but there can be little

doubt that it causes a vascular congestion of the abdominal organs, increasing the secretion of urine and promoting the menstrual discharge. It is largely employed in domestic practice, especially in rural districts, to promote or restore *menstruation*, and sometimes with a criminal intention as an abortifacient, but, so far as appears, unsuccessfully. Its fruit is held by some to be as efficient as chenopodium in the destruction and expulsion of lumbricoid *worms*, and the bruised leaves have been applied to the abdomen for the same purpose. In this manner, and also in vinous and spirituous infusion, tansy has been in vogue as a topical application for *bruises*, *sprains*, *muscular rheumatism*, *chronic ulcers*, etc. Internally, it affords relief in flatulent *colic* and is not without efficacy in *hysterical disorders*.

The *dose* of the powder of the fruit of tansy is from 10 to 40 grains (Gm. 0.60–3), and of the flowers from 20 grains to 2 drachms (Gm. 1.30–8). An infusion may be prepared with from half an ounce to an ounce (Gm. 16–32) of the seeds, or with twice that quantity of the flowers (Gm. 32–64), in a pint (Gm. 500) of boiling water, and prescribed in doses of 1 or 2 fluidounces (Gm. 32–64). The oil may be given in doses of from 1 to 4 drops (Gm. 0.05–0.25) or more.

TARAXACUM, U. S.—TARAXACUM (DANDELION).

Taraxaci radix, Br.; *Radix taraxaci cum herba*, P. G.—*Dandelion-root*, E.; *Pissenlit*, *Det de lion*, *Couronne de moine*, Fr.; *Löwenzahn*, *Pfaffenröhrchen*, G.

The root, gathered in the autumn, of *Taraxacum Dens-leonis*, *Desfontaines* (s. T. officinale, *Weber*, *T. vulgare*, *Schrank*, *Leontodon Taraxacum*, *Linne*). *Woodville*, *Med. Bot.*, plate 3; *Bentley and Trimen*, *Med. Plants*, 159.

Nat. Ord.—Compositæ, Cichoreæ.

Origin.—Dandelion is a perennial acaulescent herb, with a tuft of spreading short-stalked radical leaves, which are about 8 inches (20 Cm.) long, obovate-oblong, acute, and on the margin runcinate and coarsely serrate. The flower-heads are terminal upon the hollow scapes, about 1½ inches (38 Mm.) in diameter, and have an erect imbricate involucre and numerous ligulate, yellow, and five-toothed florets. The akene is compressed, obovate-oblong, and terminated by a silky-hairy, spreading pappus raised upon a long stalk. The plant grows in waste places, pastures, and on roadsides, and is met with in most countries of the northern hemisphere. Collected in spring and dried, the root loses from 80 to 85 per cent. in weight, but if collected in autumn the loss on drying ranges from 70 to 75 per cent.

Description.—The root is from 6 to 12 or 16 inches (15–30–40 Cm.) long, nearly cylindrical, ½ to 1 inch (12–25 Mm.) thick, crowned with several short thickish heads above and furnished with few branches below. Fresh, it is light yellowish-brown and fleshy; when dry, dark brown or blackish-brown, much wrinkled longitudinally; internally, it is white with a yellowish centre. It is inodorous and has a bitter taste. It is hygroscopic, and in damp weather rather flexible, but when dry breaks with a short fracture, showing the pale-yellow porous wood surrounded by a dark-brown cambium-line and a thick white bark, with concentric circles of milk-vessels of a brownish color, and separated by layers of thin-walled and axially elongated parenchyma. The medullium has no medullary rays, and consists mainly of ducts varying in diameter and more or less interspersed with thin-walled, elongated cells.

After frost and early in the spring the root is sweet; during the spring and summer the milk-juice becomes thicker and the bitter taste increases; the root is therefore directed to be collected late in the autumn. The spring root yields a bitterish-sweet extract. *Bentley* regards the root collected about July as most efficient.

Constituents.—The bitter principle, *taraxacin*, was obtained by *Polex* (1839) in a crystalline state by treating the milk-juice with boiling water and evaporating. *Kromayer* (1864) found it necessary to leave the aqueous solution in contact with animal charcoal, from which afterward alcohol dissolved the bitter principle, requiring treatment with lead acetate and sulphuretted hydrogen to free it from coloring matter and other principles. *Kromayer* obtained taraxacin as an amorphous bitter mass. The milk-juice contains also *resin* and *taraxacerin*, $C_{18}H_{16}O$, which is insoluble in water, crystallizes from hot alcohol, and when in an alcoholic solution has an acrid taste. The dry root yields from 5 to 7 per cent. of ash.

Dandelion-root collected in autumn is rich in inulin. *Dragendorff* (1870) obtained

FIG. 295.

Transverse section of
Taraxacum-root.

from the root collected in October 24 per cent. of inulin and a little sugar, but when collected in March only 1.74 per cent. of inulin was found, and about 18 per cent. each of uncrystallizable sugar and *levulin*, the latter being intermediate between inulin and sugar in having the composition of inulin, but being of a sweet taste, soluble in cold water, and without influence on polarized light. Frickhinger (1840), Widemann, and others had obtained notable quantities of *mannit* from the concentrated juice of dandelion, but T. and H. Smith (1849) proved that this principle does not pre-exist, and that, on the contrary, it is a product resulting from fermentation.

The presence of fermentable sugar has been observed by most investigators, and Dragendorff's observations confirm the results previously obtained by Frickhinger, Widemann, and Overbrook, that the sugar predominates in the spring root, and inulin in the root collected in autumn. It seems to follow therefrom that the extract and other preparations made from the expressed juice or by treating the autumn root with cold water should be more efficacious and less loaded with inert matters (sugar, etc.) than those obtained from the spring root. Old extract of *taraxacum* sometimes contains granular crystals of calcium lactate (Ludwig, 1861); the lactic acid is probably produced from *inosit*, which, according to Marmé (1864), exists in the leaves and stalks of dandelion, but is not found in the root.

Substitutions.—Chicory-root is not unfrequently substituted for dandelion-root in the preparation of extract and fluid extract. While the roots of the two plants, notwithstanding their resemblance, may be distinguished from each other without difficulty (see page 450), no reliable tests are known by which their pharmaceutical preparations may be distinguished. It is therefore best for pharmacists to prepare them from the properly-selected drug.

Off. Prep.—Decoction *taraxaci*, Br.; Extract. *taraxaci*, U. S., Br.; Extr. *taraxaci* fluid., U. S.; Succus *taraxaci*, Br.

Medical History.—The first distinct mention of dandelion is by Arabian medical writers, who state it to be a very efficacious deobstruent and purifier of the blood. At the close of the last century it was greatly in vogue as a remedy for chronic affections of the liver and bowels, for renal calculus, some cutaneous diseases, etc. Its diuretic qualities are recognized in its popular names, *pissenlit*, *lectiminga*, etc.

Medical Action and Uses.—Rutherford and Vignal concluded from their experiments that *taraxacum* is a very feeble hepatic stimulant. It is employed now, as formerly, in cases of *hepatic congestion* due to or associated with *atonic dyspepsia* and *constipation*. It has been regarded as useful in pulmonary *consumption*—possibly, if at all, by its action upon the stomach and bowels, and indirectly upon the liver.

Dandelion is frequently administered in decoction, of which the *dose* is from 2 to 4 fluidounces (Gm. 64–128). It is apt to ferment. The extract is of little use. The fluid extract and the juice are probably its most active forms.

TAXUS.—YEW.

If commun, Fr.; *Eibe*, G.

Taxus baccata, Linné. Bentley and Trimen, *Med. Plants*, 253.

Nat. Ord.—Coniferae.

Origin and Description.—The yew is an evergreen shrub, or more frequently a tree of very slow growth, but attaining a height of 30 or 40 feet (9–12 M.). It is indigenous to Asia from Siberia southward to the Himalaya Mountains, and westward to Syria, Northern Africa, and the greater part of Europe. It has been introduced as an ornamental tree into North America, and is naturalized to some extent. The tree has a red-brown bark, numerous and spreading (or in one variety fastigiate) branches, and closely placed, nearly sessile, and two-ranked or crowded leaves, which are linear, entire, flat, somewhat curved, acute, glossy-green above, pale-green beneath, and about 1 inch (25 Mm.) long. The fruit or berry consists of a globular-ovate, acutish or blunt, black-brown seed, surrounded by a fleshy cup-shaped scarlet-red arillus, which is open at the top, and at the base furnished with two or three rows of small scales. The young branches with the leaves attached and the fruit have been employed medicinally. The former have an unpleasant terebinthinaceous odor and a disagreeable bitter and acrid taste. The taste of the fleshy part of the berry is sweetish and not unpleasant, but the seed is bitter.

Constituents.—The leaves were examined by Peretti (1828) and Righini (1837), who, besides the common principles, found in them volatile oil, tannin, and an amorphous

bitter principle. Lucas (1843) isolated the latter in the form of an amorphous bitter powder which is sparingly soluble in water, but freely soluble in dilute acids, in alcohol, and ether. The salts of this *taxine* are uncrystallizable, and are precipitated by tannin and by alkalis. Marmé (1876) obtained the alkaloid in a crystalline condition from the leaves and in small proportion from the seeds; besides the solvents mentioned before, it is soluble also in chloroform, benzol, and carbon bisulphide, is precipitated by all group reagents of the alkaloids except the chlorides of mercury, gold, and platinum and the platino-cyanide of potassium, and is colored purplish-red by sulphuric acid, but dissolves without coloration in other acids, and has poisonous properties. Amato and Capparelli prepared from the leaves a crystalline, nitrogenated, colorless compound, *milossin*, which is insoluble in water, and a volatile alkaloid which has a peculiar musty odor and is colored green by sulphuric acid and potassium chromate, the color changing to violet on warming. The air-dry leaves yield 5.5 per cent. of ash (Roth, 1876). The red coloring matter of the arillus is soluble in alcohol and ether, but insoluble in water.

Allied Plants.—The American yew, *Taxus canadensis*, *Willdenow*, is regarded by Gray as a low, straggling variety of the above species; its leaves are mucronate, and have a revolute or subrevolute margin. The yew of the Pacific coast, *Taxus brevifolia*, *Nuttall*, is a tree growing in Oregon to the height of 50 feet (15 M.), but is smaller in California. The Irish yew, *T. hibernica*, *Mack*, has a yellow fruit. *T. nucifera*, *Kämpfer*, indigenous to Japan, has a green fruit, the fleshy portion of which is astringent and pungent, while the seed is sweet and oily.

Physiological Action.—In his account of yew Pliny says that the berries, especially of Spanish yew, contain a mortal poison, and that wine-barrels made of its wood render their contents poisonous. He relates that in Arcadia the very shadow of the yew tree is fatal to those who sleep in it, and that arrows are rendered poisonous by its juice. Dioscorides states that the berries are poisonous to birds. The poisonous effects of the emanations of this tree have been mentioned by several later observers, who have put them to the test, and it is recorded that a girl who slept all night under a yew tree suffered from a copious miliary eruption, and for days remained in a half-delirious state. The poisonous portions of the plant are its foliage and the stony seed; the fleshy covering of the latter is innocuous.

On Animals: 15 grains of the alcoholic extract of the leaves given to rabbits occasioned hurried breathing and palpitation of the heart, followed by recovery, and double the dose produced the same effects, ending in sudden death. In other cases convulsions preceded the extinction of life, but it would appear that they are least apt to occur when the dose has been large. In several experiments with such doses the animal died quietly by syncope. So in certain cases horses poisoned by yew have died suddenly without any spasm or sign of pain. According to Borchers's (1876) experiments, *taxine* reduces the pulse- and respiration-rate and causes convulsions, with fatal asphyxia (Husemann). After death the evidences of gastro-intestinal inflammation have generally been slight, the heart was usually empty, the kidneys strongly congested, and the blood less coagulated than usual.

On Man: The effects which are produced by yew on man vary materially in different cases, and, in general, the larger the dose of the poison the less definite and various are the symptoms. When they are fully developed they comprise irritation of the stomach and bowels, with vomiting, and sometimes purging, difficult urination, pallor, giddiness, prostration, coldness, spasm, or partial paralysis, irregular and feeble action of the heart, and death by coma or by syncope. The latter mode of death occurs most frequently when the dose of the poison is very large, and then the phenomena of nervous irritation and exhaustion and the gastric disturbance may be very trifling, the patient dying by rapid asthenia or by absolute syncope. In the case of a young woman who took the leaves of yew as an abortive, death occurred without convulsion, and her countenance was as natural as in sleep. In another case eleven persons partook of a decoction of yew; some of them were seized with giddiness, confusion of sight, pain in the head, nausea, and vomiting, and then fell asleep; but two of them died within an hour without pain or convulsion. The fatal dose varies greatly; a decoction of from 2 to 5 ounces has destroyed life. The lesions found after death in man produced by this poison are the same as those already mentioned as occurring in animals.

Medical Uses.—A jelly prepared from the berries of yew has been employed in the treatment of chronic catarrh of the *bronchia* and the *urinary passages*, and the leaves have been recommended in *scurvy*, *epilepsy*, and other spasmodic affections, and been used by the vulgar as an *emmenagogue*, and especially as an abortive. The efficiency of yew in these conditions is far from proven, and among the numerous cases in which it has been

employed to provoke abortion several have resulted fatally to the mother, but in none was the fetus expelled. The leaves have been prescribed in doses of from 1 to 5 grains (Gm. 0.06–0.30), or in a decoction or infusion made with from 8 to 16 grains in 4 ounces of water (Gm. 0.50–1 in Gm. 120).

In *poisoning* by this substance the stomach should be speedily evacuated, after which milk may be given in small quantities to allay the irritation, and alcoholic liquids in stimulant doses.

TEPHROSIA.—GOAT'S RUE.

Turkey pea, Hoary pea, Devil's shoestring, E.; Tephrosie, Fr., G.

Tephrosia (Galega, *Linne*) virginiana, *Persoon*. Meehan, *Native Flowers*, i. 81.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Origin and Description.—This species is an herbaceous perennial growing in sandy soil in Canada and the United States westward to the Mississippi. Its root is many-headed and divided into several nearly horizontal branches, which are about $\frac{1}{2}$ inch (12 Mm.) in diameter, 1 to 2 feet (30–60 Cm.) long, somewhat beset with fibres, rather tough and flexible, externally brown-gray and internally whitish. The stems are about 2 feet (60 Cm.) high, nearly simple, more or less woolly, and have numerous alternate, oddly-pinnate leaves, with about ten pairs of oblong, mucronate, shortly-stalked, straight-veined, and silky-villous, pale-green leaflets. The flowers are in terminal and axillary racemes, white, rose-colored, and red, and produce a curved silky legume.

The root, and occasionally the herb, have been employed; the root is without odor and has a bitterish and somewhat acrid taste.

Constituents.—The principles to which the properties of goat's rue may be due are unknown.

Allied Plants.—TEPHROSIA APPOLINEA, *De Candolle*. The leaflets have occasionally been used as a substitute for, or for the adulteration of, senna-leaves (see p. 1366).

T. TOXICARIA, Persoon, is indigenous to Africa and naturalized in tropical America. It has deep-red flowers and a poisonous root.

T. PURPUREA and *T. SPINOSA, Persoon*, indigenous to India, have bitter roots, which are employed for their tonic properties.

T. LEPTOSTACHYA, De Candolle, is a native of Senegambia. Its root and leaves are regarded as possessing purgative properties.

Medical Action and Uses.—The root as well as the leaves of the native tephrosia are said to be laxative, tonic, and *vermifuge*. For the last-named purpose a decoction of the root has been used. It may be prepared by boiling an ounce of the plant in a pint (Gm. 32 in Gm. 500) of water, to the reduction of one-half. *Dose*, 1 or 2 table-spoonfuls (Gm. 16–32). It has also been reported to be useful in the treatment of *typhoid fever*, but as it was not given alone, its value in this disease cannot be estimated.

TEREBINTHINA, U. S., P. G.—TURPENTINE.

Thus americanum, Br.; Terebinthina communis.—Crude turpentine, E.; *Térébenthine commune, Fr.; Gemeiner Terpentin, G.*

The concrete (semi-fluid, *P. G.*) oleoresin obtained from *Pinus australis* and other species of *Pinus*. Bentley and Trimen, *Med. Plants*, 256–259.

TEREBINTHINA CANADENSIS, U. S., Br.—CANADA TURPENTINE.

Balsamum canadense.—Canada balsam, *Balsam of fir, E.; Térébenthine du Canada, Baume de Canada, Fr.; Canadischer Terpentin, G.*

The liquid oleoresin obtained from *Abies* (*Pinus, Linne, s. Picea, Loud*) balsamea, *Marshall*. Michaux, *N. Amer. Sylva*, iii. t. 150; Bentley and Trimen, *Med. Plants*, 263.

Nat. Ord.—Coniferæ.

Origin.—The different species of pine and fir form resin-ducts in the bark or wood, in which liquid oleoresins secrete. Most of these oleoresins exude to some extent spontaneously, but the various turpentines of commerce are obtained by wounding the trees. Many species secrete the oleoresin in such small quantities that it is not collected. The turpentines recognized in the U. S. and British Pharmacopœias are furnished by the following species:

PINUS AUSTRALIS, *Michaux*, s. *P. palustris*, *Miller*. This is the *broom pine* or *swamp pine* of the United States, where it is very abundant from Southern Virginia to Florida, not extending more than about 100 miles from the coast. Its leaves are 10 to 15 inches (25–38 Cm.) long, crowded near the ends of the branches, and in tufts of threes, surrounded by long, ragged sheaths. The cones are nearly cylindrical, about as long as the leaves, and have the scales furnished with a short spine. This species yields nearly all the turpentine and rosin in the United States.

PINUS TEDA, *Linné*, grows in barren, sandy soil near the coast from Virginia to Florida, and is known as *loblolly* or *old-field pine*. The leaves are 8 or 10 inches (20–25 Cm.) long, in fascicles of threes, and surrounded by elongated, subentire sheaths. The cones are ovate-oblong, about one-half the size of the leaves, and have the scales tipped with a stout inflexed spine.

ABIES BALSAMEA, *Marshall*, is the *balsam fir* or *balm-of-Gilead fir* of Canada and the Northern United States. It attains a height of about 50 feet (15 M.), has numerous solitary leaves, which are about $\frac{3}{4}$ inch (2 Cm.) long, linear, flat, obtuse, and glaucous-silvery beneath, and produces cylindrical bluish cones 3 or 4 inches (7–10 Cm.) long and with scales tipped by a short spine.

ABIES FRASERI, *Pursh*, resembles the last species, but has the cones only about 2 inches (5 Cm.) in length, and the upper part of their sharp-pointed scales much projecting and recurved. It grows from New England to North Carolina, principally in the mountains, and may be used for collecting *balsam of fir*.

Collection.—COMMON TURPENTINE. In the United States turpentine is chiefly obtained in North Carolina, and more recently it has been procured from South Carolina and Georgia. During the autumn and winter the pine trees are *boxed*, one to four excavations being made, by means of an axe, through the bark into the sapwood, commencing about 6 or 8 inches (15–20 Cm.) above the roots. The bottom of these *boxes* is about 5 inches (12 Cm.) below the lower and 8 or 10 inches (20–25 Cm.) below the upper lip, and their capacity varies from 4 to 8 pints. A few days after the boxes have been cut the bark is removed above the box to the height of about 3 feet, and some of the wood is scraped off or *hacked*, the hacks being made in the shape of the letter L. The oleoresin or *crude* begins to flow about the middle of March, runs best during July and August, and slackens again in September and October. The boxes are from time to time emptied by means of a peculiarly-constructed spoon or ladle, called *turpentine-dipper*, and the turpentine is at once transferred into rudely-constructed barrels, and usually used for distilling the oil. The trees are slightly scraped every eight or ten days, and the scraping or hacking is continued until finally ladders have to be employed. The flow of the first year is the best, called *virgin dip*, and yields about 6 gallons of oil per barrel and the so-called “window-glass rosin.” *Yellow dip* is the exudation of the second and subsequent years, yields about 4 gallons of oil per barrel, and furnishes the medium grades of rosin. The turpentine which hardens upon the tree is termed *scrapings*, yields about 2 gallons of oil per barrel, and leaves a very dark-colored nearly black rosin. (See I. Zacharias, *Amer. Jour. Phar.*, 1877, 543, and Dr. T. F. Wood, *New Remedies*, 1880, 289.)

CANADA TURPENTINE is largely collected in the province of Quebec, Canada, the balsam-gatherers, with their whole families, encamping in the woods for two months each year. The turpentine is secreted in vesicles formed in the bark, each of which requires to be pierced by the sharp-pointed iron tube attached to a can, when the balsam flows into the vessel. The average yield of each tree is about 8 ounces, and a man with the aid of two children may gather about 1 gallon during the day. The trees require two or three years' rest before they are tapped again, and the yield is then always less than the first time. The largest crop ever gathered in the Laurentine Mountains of Quebec in one year was 5000 gallons. (See Wm. Saunders, *Proceedings Amer. Phar. Assoc.*, 1877, p. 337.)

Description.—TURPENTINE is a yellowish, or brownish-yellow, viscid liquid, which, when it exudes, is transparent, but soon becomes opaque from a crystalline deposit. It is rendered thinner and clear by a moderate heat, and has an agreeable terebinthinate odor and a pungent, bitterish, and acrid taste. In this condition turpentine is recognized by the pharmacopœias of continental Europe, but in the United States and in Great Britain the oleoresin which has concreted on the trees is officinal, and is generally kept under the name of *white turpentine*, and in England is known as *common frankincense*. It is identical with the granular sediment deposited from liquid turpentine, and is found in irregular yellowish-white, more or less tough masses, which contain fragments of bark and wood,

FIG. 296.

Instrument for collecting balsam of fir.

are brittle in the cold, breaking with a crummy fracture, and are more tenacious, or even semi-liquid, in warm weather. It contains from 12 to 16 per cent. of volatile oil, on the loss of which by exposure it becomes firm and friable.

CANADA TURPENTINE is a yellowish or faintly greenish, perfectly transparent, and occasionally somewhat fluorescent, viscid liquid, having a similar but more agreeable odor and taste than the preceding. On exposure it acquires a slightly darker tint and dries into a transparent, pale-yellow mass. It is completely soluble in chloroform, benzol, ether, and warm amylie alcohol, but incompletely in bisulphide of carbon, glacial acetic acid, acetone, and absolute alcohol (*Pharmacographia*).

Substitutions.—Common turpentine is not liable to adulterations, but a fictitious Canada turpentine has occasionally been sold under the name of *Oregon balsam of fir*, which was made by dissolving rosin in oil of turpentine and flavoring the solution by the addition of a little oil of wormwood. A liquid pale-yellow turpentine may be procured by puncturing the vesicles of the bark of *Abies* (*Pinus Douglasi* Menziesii, *Lindley*, the *balsam pine* of the Pacific coast. The sample in our possession slowly deposited white granular matter, and became rather opaque and solid.

Other Turpentine.—EUROPEAN TURPENTINE closely resembles American turpentine, and is obtained in Russia from *Pinus sylvestris*, *Linné*; in Germany, from the same species and from *P. rotundata*, *Link*; in Austria, from *P. Laricio*, *Poirét*; and in South-western Europe, from *P. Pinaster*, *Solander*, s. *P. maritima*, *Poirét* (Bentley and Trimen, *Med. Plants*, 256, 257). The turpentine is secreted in the sap-wood, and is obtained in a manner similar to that in which the American turpentine is procured. The concrete French or *Bordeaux turpentine* is known in European commerce as *gallipot*, and resembles white turpentine.

STRASSBURG TURPENTINE, *Terebinthina argentoratensis*, is procured, like Canada balsam, which it resembles, by puncturing the vesicles of the bark of *Abies* (*Pinus Lamarche*) pectinata, *De Candolle*, s. *Pinus Picea*, *Linné*; *P. Abies*, *Duroi*; *Abies alba*, *Miller*, A. excelsa, *Link* (Silver fir, *E.*; Sapin, *Fr.*; Weisstanne, Edeltanne, *G.* Bentley and Trimen, *Med. Plants*, 262). It is collected in the Vosges, and has an agreeable odor, somewhat resembling that of lemon.

VENICE TURPENTINE, *Terebinthina larinia*, s. *laricis*, s. *veneta*, is procured in Tyrol and Switzerland from *Larix europæa*, *De Candolle* (*L. decidua*, *Miller*, *Pinus Larix Linné*) (Bentley and Trimen, *Med. Plants*, 260). (See LARICIS CORTEX.) The oleoresin is secreted in the heart-wood, and is obtained by boring a hole into the trunk to the centre and dipping the liquid out as it accumulates. It is a nearly transparent or slightly opaque and somewhat fluorescent thick liquid, of a terebinthinate odor, a bitter and aromatic taste, and a yellowish or greenish-yellow color. It is freely soluble in alcohol, amyl alcohol, acetone, and glacial acetic acid, and does not become hard when mixed with magnesia. The article usually sold here under this name is an artificial product. 59,366 pounds of Venice turpentine were imported in 1878; the average is about 48,000 pounds.

HUNGARIAN TURPENTINE, *Balsamum hungaricum*, exudes from *Pinus Pumilio*, *Hanke*, after cutting off the tops of the branches in the spring. It is thin, transparent, yellowish, and has an aromatic odor and warm taste.

Constituents.—All turpentine consist of a volatile oil having the composition $C_{10}H_{16}$ (see OLEUM TEREBINTHINÆ) and of resin, which is left behind on distilling the oil, and then constitutes rosin. (See RESINA.) The transparent turpentine, according to Maly, are solutions of *abietic anhydride* in the volatile oil, and on exposure to a moist atmosphere gradually become turbid and opaque from the crystallization of *abietic acid*. But the resin contained in those turpentine which do not become opaque on exposure must necessarily be different. Hot water agitated with turpentine acquires an acid reaction from the presence of formic, and probably also of succinic, acid, and the alcoholic solution of turpentine has a strong acid reaction.

Other Products of Pines.—TURIONES (GEMMÆ) PINI.—Pine-shoots, *E.*; Bourgeons de pin (sapin), *Fr.*; Fichtensprossen, *G.*—The young shoots of *P. sylvestris*, collected when about 2 inches (5 Cml.) long, are glutinous from an oleoresinous exudation, and have an agreeable terebinthinate odor and a bitter, resinous, and rather acid taste.

OLEUM PINI FOLIORUM.—Pine-leaf oil, Fir-wood oil, *E.*; Essence de feuilles de pin, *Fr.*; Kiefer-nadelöl, Waldwollöl, *G.*—The leaves of the different species of pine by pounding are converted into a fibrous substance known as *Fichtenwolle* (*fir-wool*), and when distilled with water yield a volatile oil which differs from the volatile oil obtained from the resin of the same species. It is of a green-yellow color, is limpid, has an agreeable terebinthinate and somewhat lavender-like odor, and is soluble in about seven times its volume of alcohol sp. gr. .838. The volatile oil is recognized as OLEUM PINI SYLVESTRIS, *Br.*

OLEUM TEMPLINUM is distilled from the shoots of *Pinus Pumilio*, and is known in Germany as

Krummholzöl and *Latschenöl*. It is colorless or yellowish-green, and of an agreeable somewhat terebinthinate odor. The volatile oils of *Pinus sabiniana*, Douglas, and of other species of pine indigenous to California resemble these products.

Allied Oleoresins.—TEREBINTHINA CHIA, S. CYPRIA, *Chian turpentine*, is the turpentine of ancient authors. It is obtained from incisions made in the bark of *Pistacia Terebinthus*, Linné (nat. ord. Anacardiaceæ; Bentley and Trimen, *Med. Plants*, 69). This species is a small tree found in the basin of the Mediterranean and eastward in Asia. The oleoresin is greenish-yellow or brownish, transparent, has a terebinthinate and somewhat fennel-like odor and a mild bitterish taste, and hardens to a transparent resin.

BALSAMUM GILEADENSE (see p. 1009).

CARANNA is a soft oleoresin of a greenish-brown or brownish-green color coming from Central and South America, and probably obtained from *Leica Caranna*, Kunth, and other trees of the nat. ord. Burseraceæ. It has an agreeable balsamic odor and a bitterish taste.

TACAMAHACA is the product of *Elaphrium tomentosum*, Jacquin, and probably of several South American trees (nat. ord. Burseraceæ). It is in brown or yellowish translucent pieces, of an aromatic odor, and breaking with a smooth and glossy fracture. The exudations of *Calophyllum Tacamahaca*, Willdenow, and *Cal. inophyllum*, Linné (nat. ord. Guttiferae), indigenous to India and the islands of the Indian Ocean, have been used under the same name. Their odor bears a resemblance to lavender and fennel. The seeds of the last-named species contain from 50 to 60 per cent. of fixed oil, known in Indian commerce as *bitter oil* or *weandee*; it is butyraceous, green, aromatic, and is in great repute for rheumatic complaints.

ANIME. South American anime is probably derived from some species of the nat. ord. Burseraceæ, though it has been referred to *Hymenæa Courbaril*, Linné (nat. ord. Leguminosæ). It is in yellowish-white or brownish, rather opaque pieces, which soften between the teeth and have an odor resembling that of olibanum. East Indian anime is reddish and yellowish, friable, of a waxy lustre, and has a somewhat fennel-like odor.

Pharmaceutical Products.—TINCTURA PINI COMPOSITA.—Compound tincture of pine-shoots. *E.*: Teinture de sapin composée, *Fr.*; Holztinktur, *G.*—Macerate for 8 days young pine-shoots 3 parts, guaiac-wood 2 parts, sassafras-root and juniper-berries, each 1 part, in alcohol (sp. gr. .892) 36 parts; express and filter.—*P. G.* 1872.

SYRUP OF PINE-SHOOTS, *E.*; Sirop de bourgeons de pin, *Fr.*—Macerate for 12 hours 100 parts of young pine-shoots with an equal weight of alcohol; add 1000 parts of hot water, digest for 6 hours, express, filter, and dissolve 180 parts of sugar in every 100 parts of the filtrate.—*F. Cod.*

Off. Prep.—Of *turpentine*: Empl. galbani comp., *U. S.*; Empl. picis, *Br.* Of *Canada turpentine*: Charta cantharidis (epispastica), Collodium flexile, *U. S.*, *Br.*; Emplastrum ferri, *U. S.*

Medical Uses.—Turpentine is seldom or never used in medicine, as its virtues depend entirely upon its volatile oil (see OL. TEREBINTHINÆ), which is separately employed. In ancient times it was prescribed chiefly as a stimulant in *amenorrhœa*, as a diuretic, as a remedy for catarrhal affections of the *urino-genital* organs and of the *lungs*, and in *ulceration of the bowels*, *hæmorrhoids*, and *rheumatism*. Externally, it was applied in the treatment of *itch* and of numerous chronic diseases of the *skin*, and its vapor, at a high temperature, as a bath in *chronic rheumatism*. The dose of turpentine may be stated at from 20 to 60 grains (Gm. 1.30–4).

Under the name of Canada balsam, balsam of fir, and even under the deceptive title of balm of Gilead, Canada turpentine has been used, especially in the treatment of chronic *bronchitis*, as well as for the purposes to which other turpentines are applied. It is destitute of the special qualities of the true balsams, since it does not contain benzoic acid.

The resin of tacamahaca was formerly used in fumigations for *rheumatism* and in plasters for that affection, *sprains*, and other local disorders requiring stimulation or mechanical support. It was also given internally, associated with amber, cloves, nutmeg, etc.

CHIAN TURPENTINE was introduced as a remedy for *uterine cancer* in 1880 by Prof. Clay of Birmingham, Eng. It was given internally, and in a maximum dose of 25 grains. Its effects were thus described: "It appears to act upon the periphery of the growth with great vigor, causing the speedy disappearance of what is usually termed the cancerous infiltration. . . . It appears to dissolve the cancer-cells, . . . and the firmer structures gradually gain a comparatively normal condition. . . . It is a most efficient anodyne" (*Lancet*, Mar. 27 and Oct. 2, 1880). On the other hand, Dr. Henry Morris (*Lancet*, Dec. 4, 1880) declared that the drug did not exercise a favorable influence over a single symptom of cancer, and that as a cure it was utterly valueless. To the latter opinion all experts in the matter have rallied.

TEUCRIUM.—GERMANDER.

Herba mari veri.—*Herb mastich*, Cat *thyme*, E.; *Germandrée maritime*, Fr.; *Gamander*, *Katzengamander*, *Amberkraut*, G.

Teucrium Marum, Linné.

Nat. Ord.—Labiatae, Ajugoideae.

Description.—Of the numerous species of the genus *Teucrium* which are occasionally employed in medicine, nearly all are indigenous to Europe. The genus is characterized by its flowers, which have the lower lip elongated and the upper lip short and deeply divided, the four stamens projecting from the cleft. All are aromatic and more or less bitter. The above-named species is shrubby, about 10 inches (30 Cm.) high, and much branched. The leaves are about $\frac{1}{2}$ inch (8 Mm.) long, petiolate, oval or lanceovate, with the margin entire and revolute, and whitish tomentose beneath. The rose-red flowers are single in the axils of the bracts, forming a one-sided, spike-like raceme. The odor is strongly camphoraceous, the taste pungent and bitter.

Allied Plants.—TEUCRIUM CANADENSE, Linné.—Woodsage, E.—It is downy or hairy, of a grayish-green color, and about 2 feet (60 Cm.) high. The leaves are about 2 inches (5 Cm.) long, short-stalked, lance-ovate, rounded at the base and serrate on the margin. The pale-purple flowers are in whorls of about six, and form a terminal spike.

T. SCORDIUM, Linné; *Herba scordii*.—Water germander, E.; *Germandrée aquatique*, Fr.; *Lachenknoblauch*, G.—It is about 12 inches (30 Cm.) high, has sessile, lance-oblong, serrate, and soft hairy leaves about $1\frac{1}{2}$ inches (38 Mm.) long, and rose-colored flowers in whorls of two to four. In the fresh state it has an alliaceous odor.

T. POLIUM, Linné.—Polymountain, E.; *Polium*, Fr.; *Bergpoley*, G.—The leaves are $\frac{1}{2}$ inch (12 Mm.) long, tomentose, sessile, lance-linear, obtuse, crenate, and strongly revolute on the margin. The flowers are white. The allied T. montanum, Linné, has yellowish flowers.

T. CHAMÆDRYS, Linné.—Petit-chêne, Fr.—It is low, suffruticose, and branching. The leaves are about an inch (25 Mm.) long, petiolate, hairy, ovate or obovate, obtuse, cuneate at base, and crenate serrate. The flowers are purplish-red.

AJUGA (TEUCRIUM, Linné) CHAMÆPTYS, Schreber.—Ground pine, E.; *Ivette*, Fr.; *Günsel*, *Feldcypresse*, G.—A small hairy annual with axillary flowers, having the yellow corolla dotted with purple; the lower-leaves are lanceolate, the upper ones three-cleft with linear lobes; the odor is rosemary-like.

AJUGA (TEUCRIUM, Linné) IVA, Schreber.—French ground pine, E.; *Ivette musquée*, Fr.; *Bisangünsel*, G.—It resembles the preceding, but has linear, somewhat toothed, woolly leaves, red flowers, and a musk-like odor. This and the preceding two species are officinal in the French Codex.

AJUGA REPTANS and A. PYRAMIDALIS, Linné, are small perennials with obovate crenate radical leaves and blue flowers, are slightly aromatic and somewhat bitter, and are known in Europe as *bugle* and *mountain bugle*.

Constituents.—These species owe their virtues to volatile oil, to a small quantity of bitter principle, and to tannin.

Medical Action and Uses.—The numerous species of *Teucrium* appear to possess similar qualities in different degrees, and among them T. marum, or germander, has enjoyed the greatest reputation. It is described as tonic, stimulant, diaphoretic, diuretic, and emmenagogue, and has been used in *scrofula*, *chlorosis*, *chronic bronchitis*, *leucorrhœa*, *amenorrhœa*, *dropsy*, *chronic gout*, etc.—in a word, in various affections requiring a stimulant and tonic treatment. A snuff made from its powder has been employed to cure *nasal polypi*. *Teucrium* is administered in powder in the dose of 30 or 40 grains (Gm. 2–2.30), or in an infusion made with from half an ounce to an ounce in a pint (Gm. 16–32 in Gm. 500) of water.

THAPSIA.—THAPSIA.

Thapsie, *Faux fenouil*, Fr.; *Thapsie*, G.

Thapsia garganica, Linné.

Nat. Ord.—Umbelliferae, Orthospermæ.

Origin and Description.—This plant is a perennial herb of Northern Africa and Southern Europe, and has a smooth, thick, and hollow stem; smooth, shining, twice or thrice-pinnate leaves, with large sheaths and lance-linear, acute, often two- or three-lobed leaflets; and pale-yellow flowers in large compound umbels. The root is usually employed. It is about 2 feet (60 Cm.) long, about 2 inches (5 Cm.) thick, gradually

tapering, somewhat branched, brownish-gray externally and internally whitish. When fresh it contains a white acrid juice. It is nearly inodorous and has a biting, acrid taste.

The closely-allied *Th. Sylphium*, *Viviani*, of Northern Africa, is, like the *Narthex Sylphium*, *Oersted*, regarded as a mere variety of the preceding plant, which is by some believed to be identical with the *Sylphium cyrenaicum* of the ancients.

Constituents.—The acrid properties are due to a resin which is neutral and free from nitrogen, crystallizes in needles, and is soluble in hot alcohol, in ether, and in carbon bisulphide. Canzoneri (1883) found in the resinous extract also an octoic acid, $C_8H_{16}O_2$, closely related to caprylic acid, and *thapsic acid*, $C_{16}H_{30}O_4$, which is scaly, melts near 124° C. (255° F.), and is nearly insoluble in water, benzol, and carbon bisulphide.

Pharmaceutical Uses.—*RESINA THAPSIAE*. Exhaust the bark of the root with alcohol and evaporate to a soft extract.—*F. Cod.*

THAPSIA PLASTER contains 7 per cent. of the resin, combined with yellow wax, colophony, and turpentine.—*F. Cod.*

Medical Action and Uses.—Galen, Dioscorides, and the Arabians agree in describing the powdered root and juice of this plant as being irritating to the skin, and, when taken internally, as emetic and purgative. The juice and ointments and plasters prepared with it were used as stimulants and counter-irritants for the relief of rheumatic and other local pains and to lessen dyspnoea. About 1868 some attempts were made to revive its use in the form of the resin extracted from the root. Applied in a plaster, the skin became inflamed, with intolerable itching, and a copious vesicular eruption ensued. If the application was not prolonged, this eruption speedily dried up, but in the contrary case the vesicles became confluent, broke, and exposed an ulcerated and suppurating surface, which on healing left scars resembling those of small-pox. On delicate skins its operation was extremely severe. It is stated that the men employed in preparing extract of thapsia on a large scale were affected with fever and swelling of the hands and face, and from time to time were obliged to suspend their work. A case is also related in which the application of a plaster of thapsia resin to the chest was followed in about 12 hours by severe strangury and violent itching about the genitals and anus. In the Therapeutical Society of Paris all the leading members of that body condemned thapsia plasters as unnecessary, and as sometimes dangerous (*Bull. et Mém. Soc. théér.*, Avr. 1882, p. 101). It does not appear that its therapeutic operation differs in any wise from that of other counter-irritants, such as croton oil, euphorbium, mezereon, and tartar emetic, but it may be added to the number of such agents for occasional use. The resin may be mixed with diachylon in the form of a plaster, or ordinary adhesive plaster may be coated with an alcoholic solution of the resin and applied to the skin.

THEA.—TEA.

Thé, Fr.; *Thee*, G.

The leaves of *Thea chinensis*, *Sims* (*Camellia Thea*, *Link*, *C. theifera*, *Griffith*). Bentley and Trimen, *Med. Plants*, 34.

Nat. Ord.—*Ternstroëmiaceæ* (*Camelliaceæ*).

Origin.—Tea is obtained from a shrub which is indigenous to China and probably to other parts of Southern and South-eastern Asia, and has been cultivated in India, China, and Japan from a very early period. The varieties produced by long cultivation were formerly regarded as distinct species, and described as *Thea Bohea*, *T. viridis*, *T. stricta*, etc. The plant has been successfully introduced in several parts of the United States. It bears white axillary flowers and roundish-triangular, three-celled, and three-seeded capsules. The seeds are subglobular, somewhat flattened, of the size of a cherry-stone, glossy-brown, yellow at the hilum, and have a brittle testa, a short radicle, and unequal thick plano-convex cotyledons.

Preparation.—After the leaves have been gathered they are either rapidly dried, when they change to a dull-green color (*green tea*), or they are allowed to wilt, and are subsequently kept for some time in heaps, when they acquire a dark color (*black tea*). Both varieties are subjected to various manipulations, such as rolling upon a table, heating over a fire, etc., and are sometimes flavored by being left in contact with the flowers of the orange, fragrant olive, jessamin, and others. Hyson, Young Hyson, Gunpowder, and Imperial are some of the best-known brands of green tea, and Souchong, Oolong, and Pekoe are black teas.

Description.—Tea is met with in commerce in the form of little cylinders or rolls, into which the leaves have been twisted during the manipulation of rolling, and in some

FIG. 297.

Tea-leaves: natural size.

varieties these leaves have again been formed into balls of different sizes. Tea-leaves after having been softened in water and unfolded are found to be from 1 to 3 inches (25–75 Mm.) long, varying between oblong-ovate and oblanceolate in shape, short-stalked, pointed at both ends or blunt, sometimes emarginate at the apex and irregularly toothed at the margin. They have a prominent midrib, the lateral branches of which are curved upward near the margin. Tea has an agreeable odor, which varies, however, in the different varieties; its taste is pleasantly astringent and bitterish. The green color is not unfrequently heightened or imparted to tea by a mixture of Prussian blue and gypsum.

Constituents.—Tea contains 1 to 2, or sometimes 4, per cent. of *theine*, which was discovered by Oudry (1827), and by Mulder and Jobst (1838) proved to be identical with caffeine (see page 342). It may be obtained by sublimation on carefully heating powdered tea-leaves, or, according to Caze-neuve and Caillot (1877), by macerating in a water-bath and drying a mixture of 1 part of cut tea-leaves, 4 of water, and 1 of slaked lime; the residue is exhausted with chloroform; this is distilled off, and the greenish mass treated with boiling water; the solution is passed through a moist filter, and on cooling and concentrating yields the

alkaloid. Mulder obtained from tea between 13 and 18 per cent. of tannin, which, according to Peligot, is peculiar, and, according to Stenhouse, differs from gallo-tannic acid and is accompanied by a little gallic acid. Rochleder (1848), on the contrary, found a small quantity of tannin identical with that of nutgalls, and a smaller proportion of *boheic acid*, $C_{11}H_{20}O_{12}$, which is amorphous, deliquescent, freely soluble in water and alcohol, and is colored brown, but not precipitated, by ferric chloride. Peligot found tea-leaves to contain pectin. Mulder obtained about 3 per cent. of albumen, 2 to nearly 4 per cent. of wax and resin, aside from the chlorophyll, and between 0.6 and 1 per cent. of volatile oil, which necessarily must vary with the variety of tea yielding it; it is of a lemon-yellow color, has a strong aromatic odor and taste, and congeals readily. Tea yields between 4 and 6 per cent. of ash, about two-thirds of which is soluble in water; but on extracting tea-leaves with water, one-half to three-fourths or more of the mineral constituents enter the infusion. The ash contains from 38 to 48 per cent. of potassa and from 11 to 26 per cent. of phosphoric acid. The nitrogen of the leaves varies between 4 and 7 per cent. R. Weyrich (1872) found it impossible to determine chemically the value of tea: the best results were obtained from determining the phosphoric acid, which was always present in largest proportion in the best qualities, but varies greatly in the different varieties, green tea yielding 11.6 to 13.3 per cent., black tea 13.1 to 17.3 per cent., yellow tea 18.5 to 25 per cent., etc.

By expression tea-seeds yield about 35 per cent. of comestible oil, which resembles olive oil, is of a yellow color, has the spec. grav. .927, becomes turbid below 5° C. (41° F.), and congeals at about –60° C. (21° F.); it consists of olein and stearin.

Allied Plants.—*THEA* (*CAMELLIA*, *Linne*) *JAPONICA*, *Baillon*, s. *Thea Camellia*, *Hoffmann*. The seeds of this well-known ornamental shrub are regarded as poisonous in Japan. Katzu-yama (1878) isolated from them tannin, acrid soft fixed oil, and *camellin*, which is nearly insoluble in cold water and ether, is freely soluble in water, turns yellow by alkalis, and red by sulphuric acid containing nitric acid, and appears to be a glucoside.

CAMELLIA OLEIFERA, *Abel* (*Thea oleosa*, *Loureiro*), and *CAM. DRUPIFERA*, *Loureiro*. The seeds, like tea-seeds, yield bland fixed oils, that of the last species having an agreeable odor.

Physiological Action.—*On Animals*: Long ago Lettsom proved that the fragrant and volatile substance which may be distilled from an infusion of tea was capable

of paralyzing the hinder limbs of a frog, and even of causing the death of the animal when introduced into a wound in its abdomen. In 1868, Leven (*Amer. Jour. of Med. Sci.*, July, 1868, p. 260) experimented upon frogs with theine and caffeine, and concluded that to these animals the former was the less powerful poison of the two, since twice as much of it as of caffeine was required to produce the same effects. Yet it excited convulsive movements in the animals' limbs, which caffeine did not. In other respects the physiological actions of the two alkaloids were identical. They both seemed to directly excite the heart and the respiratory movements, and to increase arterial tension. They both appeared to stimulate the brain and the spinal marrow, but not to arrest the functions of either. The tetanic convulsions were attributed by Leven to excitation of the spinal cord. Both appeared to abolish muscular contractility, but the heart continued to beat after general death. The experiments of Dr. A. Bennett, on the other hand, which were made upon frogs, mice, rabbits, and cats, led him to conclude that theine and caffeine are identical throughout the whole range of their action, and he especially made no distinction between the convulsifying operations of the two alkaloids. According to this experimenter, theine in small doses produces cerebral excitement, not succeeded by coma, and partial loss of sensibility, and in large doses occasions cerebral excitement, paralysis of sensibility, tetanic spasm, convulsions, and death. Further, it does not cause muscular paralysis, but at first it produces contraction, and afterward dilatation, of the capillaries and small blood-vessels, with stasis of the blood in them (*Edinb. Med. Jour.*, xix. 323).

On Man: The most familiar effect of tea is its power of inducing a cheerfulness of disposition and a lively flow of ideas, without that tendency to mental and physical torpor which follows the exhilaration caused by alcohol. The familiar line of Cowper, "The cups that cheer, but not inebriate," describes its usual mode of action. There can be no doubt that, like its congeners, tea diminishes the need of food even while it quickens the activity of the nervous system. In this way, probably, it has become the favorite drink of women, whose sedentary lives impede the activity of tissue-waste, without lessening the craving peculiar to their sex for lively conversation. Tea imparts to them the mental activity which their ordinary occupations restrain. It also tends to banish the drowsiness which their monotonous labor induces. Many men have been great tea-drinkers, but they were chiefly of the class addicted to prolonged mental labor, particularly at night; and they found in it not only the power of resisting sleep, but often the inspiration of bright ideas. It is evident that these effects, which are notorious and familiar, must be attributed to the direct stimulation of the brain, and by no means to the restriction of tissue-change, which is too often regarded as the prime, and indeed the sole, effect of tea. The latter is, undoubtedly, a real result of tea-drinking, but it is not that for which tea is so universally employed. It has been alleged that persons employed in tasting tea for commercial purposes are liable to lose their health and grow morbidly nervous, their bowels become constipated, and the urine and the proportion of urea in it suffer diminution (Morton, *Monthly Abstract*, Jan. 1880, p. 54). It is affirmed as positively, on the other hand, that none of these alleged effects occur, so far as relates to derangement of the nervous system and the general health (Dana, *Medical Record*, xvii. 85).

In comparing the physiological effects of theine and caffeine upon the excretions, it has been found by some experimenters that the former does not affect the elimination of carbonic acid, while the latter diminishes it, as well as the discharge of urea, uric acid, and water, in a larger proportions than theine. Caffeine also is said to increase the watery constituent of the urine, while theine diminishes it. However this may be, it is a matter of familiar observation that the effects of tea and coffee upon the system are by no means identical; for while coffee causes wakefulness as well as tea, in the former case it is rather a pleasing insomnia, not unlike that occasioned by small doses of opium, tranquil for the most part, and filled with pleasing reveries; while tea, on the other hand, induces in one who endeavors in vain to sleep after its use a state of tension of the nervous system which is in the highest degree distressing. Upon almost every one coffee acts as a stimulant which is more or less cordial, flushing the face and rendering the pulse fuller, but such effects never follow the use of tea as direct consequences. It is seldom that a single indulgence in strong coffee induces that nervous agitation and tremulousness and impaired muscular power which are ordinary effects of strong tea; and, unless we are greatly mistaken, gastralgia and other neuralgic affections are much more frequent among tea-drinkers than coffee-drinkers. It is very true that some of these apparent differences may be explained by the fact that tea is generally taken with only a small modicum of

cream or milk, while coffee is as commonly used with a large proportion of one or both. Indeed, in France, where coffee is the universal breakfast drink, it is always mixed with a great excess of milk, and it is used pure chiefly after dinner, when the presence of food in the stomach retards its absorption and modifies its action. It is, however, customary for those who have mental or bodily work to perform before breakfast to take a cup of "black coffee" immediately on leaving bed.

It has been already objected that theine and caffeine do not fully represent the sources from which they are respectively obtained. The identity of these alkaloids in their physiological action does not imply a similar identity in tea and coffee. As little should we be entitled to infer that all alcoholic drinks produce identical effects because they all contain alcohol as their chief constituent. It is just as certain that tea and coffee differ in their action upon the human system as that Rhenish or Bordeaux wine acts very differently from whiskey or brandy, although in all of these liquors the common cause of their effects is alcohol. Moreover, not only are theine and caffeine physiologically identical, but so are guaranine, cocaine, and theobromine with them and with one another; and yet the operations of guarana, coca, and theobroma are different from one another, and from those of tea and coffee, in important particulars. It is unquestionably a fact of the highest possible interest that all of these vegetable products, which are used by different and remote nations, should contain identical proximate principles; but while we thus are led to admire the universality of physiological laws, we should not lose sight of the peculiarities which distinguish these important articles of human food from one another.

Medical Uses.—When tea was introduced into Europe by the Dutch about the middle of the seventeenth century, it became the subject of extravagant eulogy, and was declared to be a remedy for all bodily ills and a sure means of prolonging life. Among the virtues attributed to it were these: that it cured headache and difficulty of breathing, prevented stone and gravel and the lassitude and laborious digestion of heavy eaters, dispelled distressing dreams, quickened the memory, and overcame drowsiness, so that, as one of its early historians phrases it, "whole nights might be spent in study without hurt to the body." An exaggeration of its virtues in a different manner is perhaps chargeable upon a late writer on dietetics, when he intimates that the substitution of tea and coffee for malt and distilled liquors at ordinary meals has tended to limit the vice of drunkenness and promote that "diffusion of mental industry and mental acquirements which constitutes the most striking physiological phenomenon of the condition of the European races of mankind at the present day." But as, in point of fact, drunkenness is more prevalent now than in any former generation, it may quite as rationally be questioned whether the mental activity, over-stimulated by tea and coffee, has not instinctively sought a counterpoison in alcohol.

Among the Chinese, we are told, tea is held to be "cooling, peptic, exhilarating, stimulating, both laxative and astringent, diuretic, emmenagogue, and, in large concentrated doses, emetic. It is applied in a wash to the eyes, ulcers, and wounds of all kinds, but its excessive use as a drink renders people thin, anæmic, and weak-sighted. Tea is taken by Chinese scholars and laborers to stave off the cravings of hunger until a convenient season arrives." The Chinese also prescribe tea, acidulated with vinegar, in *diarrhoea*, and give it as an antidote to the poisonous action of *tartar emetic* and *corrosive sublimate*. The small proportion of tannic acid contained in tea renders it too feeble a remedy in such cases if stronger ones can be procured, but its stimulant and exhilarant action adapts it to be used as an antidote to *poisoning by opium*. A cup of hot tea is a familiar domestic remedy for the relief of nausea and oppression after too full a meal, to produce diaphoresis at the commencement of slight attacks of *muscular rheumatism*, *pulmonary catarrh*, or *sore throat*, and to banish the sense of fatigue and muscular soreness produced by excessive exertion, particularly when it is seasoned with some alcohol. It is one of the best remedies for *nervous headache*, and when cold or acidulated with lemon-juice is a most refreshing drink in midsummer heats which produce excessive perspiration. It moderates also the copious *sweats* of hectic conditions. A strong infusion of green tea has been used by injection in *gonorrhœa*, *leucorrhœa*, and *gleet*, and as a wash in *conjunctivitis*, as a gargle in *sore throat*, etc. In China it is often used for certain of these purposes as a fine powder mixed with water, or in decoction rather than in infusion; and doubtless in these forms its operation is more energetic.

THEOBROMA.—CACAO.

Semen (s. Fabæ) cacao.—*Cucacó, Fèves du Mexique, Fr.*; *Kakaobohnen, G.*

The seeds of *Theobroma Cacao*, *Linné*. *Bentley and Trimen, Med. Plants*, 38.

Nat. Ord.—*Sterculiaceæ, Buettneriææ*.

Origin.—The cacao (often incorrectly called *cocoa*) or *chocolate tree* is indigenous to Brazil and other parts of tropical America northward to Mexico, and is largely cultivated throughout the tropics. It is about 40 feet (12 M.) high, has alternate, oblong-lanceolate or lance-ovate, acute, and entire leaves, and produces pale-pink, five-petalled flowers in clusters from the axils of old leaf-scars. The fruit is about 6 inches (15 Cm.) long, pear-shaped, with an elongated nipple-shaped apex, ten-furrowed and while unripe five-celled, and contains numerous seeds imbedded in a sweet pulpy mass.

Preparation.—Cacao-seeds are prepared for use by removing them from the fruit and simply drying them, in which case they retain their astringent and bitter taste; or they are subjected to a sweating process by enclosing them in a box or burying them in the ground for two or three days, whereby they lose much of their astringency and bitterness, and change in color; the best cured cacao is kept in heaps covered with plantain or other green leaves, for about a week before it is finally dried. The seeds of *Th. bicolor, Humboldt*, *Th. guayanensis, Willdenow*, *Th. sylvestre, Martius*, *Th. ovatifolium, Sessé*, and other species are stated to be collected, prepared, and mixed with the seeds of the cacao; but, according to Karsten, these uncultivated species do not furnish any commercial cacao. The seeds of *Herrania albiflora, Goudot*, and several other species appear to have the properties of cacao, and are used like the latter in the mountain-districts of South America under the name of *cacao cimarrona*, but they are only of about the size of a pea and do not enter commerce. The consumption of cacao-seeds in South America and South-western Europe has been estimated at over 100,000,000 pounds annually.

Description.—The seeds are $\frac{3}{8}$ to 1 inch (15–25 Mm.) long, ovate or oblong, somewhat flattened, and vary in color, according to the manner in which they have been prepared, from brown-red to brown or grayish-brown. A prominent raphe runs along one edge of the seed from one end to the other, uniting the hilum and chalaza, and is divided at the latter into many branching nerves. The testa is thin, papery, and fragile. The embryo has the shape of the seed, and consists of a small conical radicle and two large oily cotyledons, which are strongly ribbed upon their face, and by the projecting folds of the inner seed-coat are divided from the back into numerous small irregular lobes, so that they readily break into many angular pieces. The odor of cacao-seeds is slight, but on warming is agreeably aromatic; their taste is oily, aromatic, and bitterish.

Constituents.—The quantitative analyses by Lampadius, Tuchen (1857), and A. Mitscherlich (1859) vary greatly in their results. Lampadius found the seeds to yield about 12 per cent. of husks or shells and about 88 per cent. of kernels, and the latter to contain about 53 per cent. of fat. Mitscherlich obtained from the seeds nearly 50 per cent. of fat, 14 to 18 per cent. of starch, 13 to 18 per cent. of proteids, 1.2 to 1.5 per cent. of theobromine, 3.5 per cent. of ash, and 0.6 per cent. of sugar. Tuchen found also about 3 per cent. of gluten, and isolated between 4.5 and 6.6 per cent. of *cacao-red*. The latter is soluble in water and alcohol, precipitated by acetate of lead, and is generated in the seeds during the sweating process; it appears to be combined with a proteid, and when pure has a carmine-red color, does not change the color of litmus, and is insoluble in litmus and fixed oils. *Oil of theobroma* is described on page 1094. The odorous principle of cacao appears to be somewhat volatile, but has not been isolated. *Theobromine*, $C_7H_5N_4O_2$ (molecular weight 180), was discovered by Woskresensky (1841), and was found by Bley (1842) to be present also in small proportion in cacao-shells. The alkaloid is obtained from the infusion of cacao by precipitating it with acetate of lead, removing the excess of lead by sulphuretted hydrogen, evaporating and exhausting the residue with boiling alcohol, from which the alkaloid separates in minute colorless or white bitter crystals which are sparingly soluble in cold water, alcohol, and ether, and require for solution 55 parts of boiling water, 47 parts of boiling alcohol, and 600 parts of boiling ether. The alkaloid sublimes without decomposition at 290° C. (554° F.), and has a neutral reaction, but yields with acids crystallizable salts which are decomposed by water. Strecker converted theobromine into caffeine by heating the silver compound of the former with methyl iodide to 100° C. (212° F.). From Trojanowsky's researches (1875), it appears that the ash of the kernel is usually a little below 3 per cent., and should not materially exceed that amount; starch was found to vary between 2.23 and 6.65 per

cent., the fat from 39.3 to 52.05 per cent., and the theobromine from 1.265 to 4.652 per cent., while the shells alone yielded from 0.866 to 4.540 per cent. of the alkaloid.

Uses.—Cacao-seeds are employed for preparing butter of cacao (p. 1694) by expressing them between heated iron plates. The press-cake, ground either by itself or with starchy substances, is sold as *cocoa*. The seeds, ground together, while warm with about their own weight of sugar, constitute *chocolate*. This is usually flavored with about $\frac{1}{4}$ per cent. of cinnamon or other aromatics, and occasionally various amylaceous or mucilaginous substances are added to it.

The following formulas are taken from the French Codex, the last two from F. Cod. 1866:

CHOCOLATA SIMPLICIOR.—Simple chocolate, *E.*; Chocolat de santé, *Fr.*—3000 parts each of Caraccas and Marañon cacao are well cleaned, torrefied, deprived of the shells, and the remaining kernels reduced in a heated mortar to a paste, which is well mixed with 5000 parts of sugar and 30 parts of powdered cinnamon, and transferred to a hot slab, where it is worked with a roller until uniformly mixed; the mass is now transferred to sheet-tin moulds, the surfaces rendered smooth by beating, and, after cooling, the cakes are wrapped in tin-foil.

CHOCOLATA CUM FERRO.—Iron chocolate, *E.*; Chocolat ferrugineux, *Fr.*—Mix 10 parts of ferric oxide with 990 parts of simple chocolate.

CHOCOLATA CUM VANILLA. Vanilla 4 parts; sugar 36 parts; chocolate without cinnamon 1000 parts.

CHOCOLATA CUM CETRARIA.—Iceland moss chocolate, *E.*; Chocolat au lichen d'Islande, *Fr.*—Mix 100 parts of saccharated powdered Iceland moss jelly (see page 419) with 1000 parts of simple chocolate.

CHOCOLATA CUM SALEP.—Salep chocolate, *E.*; Chocolat au salep, *Fr.*—Incorporate 30 parts of powdered salep with 1000 parts of simple chocolate.

Preparations analogous to the latter are made by substituting powdered tapioca, sago, or arrowroot for the salep, and the aromatics are often varied by replacing the cinnamon wholly or in part with powdered cloves, mace, nutmeg, cardamom, or vanilla sugar. Chocolate has also been medicated by incorporating with 1000 parts of simple chocolate 30 parts of powdered catechu, or 60 parts of guarana or powdered cinchona, or 100 parts of calcined magnesia, etc. Chocolate has been proposed as a pleasant vehicle in the preparation of lozenges containing santolin, etc.

Medical Action and Uses.—The dietetic uses of chocolate do not require any detailed notice in this place. Prepared with water or milk, it is employed as a substitute for coffee in Southern Europe, South America, Mexico, and the West Indies, and to a less degree in other civilized countries. It is difficult to discern in it, when thus used, any of the stimulating qualities which belong to the theobromine it contains. It is to be preferred to the other agents mentioned when a nutritive rather than an excitant operation is desired; and hence it is familiarly employed during convalescence from acute diseases, and as a substitute for tea or coffee in the diet of persons whose nervous system is liable to be deranged by them. Chocolate prepared with milk, and seasoned by the addition of a modicum of coffee, is less stimulating than the latter and more palatable than chocolate alone.

The physiological action of theobromine has been investigated by Mitscherlich. 15 grains of it dissolved in water and administered hypodermically to rabbits occasioned grinding of the teeth, slowing of the respiration even to a third or a fourth of the normal rate, reduction of the temperature, increased frequency and diminished force of the pulse, and convulsions of spinal origin. When the poison was more slowly absorbed the animals lost their muscular power gradually. There was no diuresis nor any thirst or loss of appetite. Occasionally there was retching or vomiting. In frogs the lungs and bladder were distended. Death appeared to be due to paralysis of the vagus or spinal cord, and, when the poison was rapidly absorbed, spinal convulsions hastened the end. When it occurred promptly, there was long-continued irritability of the voluntary muscles and persistence of the peristaltic movements of the intestine; when the poisoning took place more gradually, the heart and voluntary muscles lost their irritability; the ventricles were contracted; the auricles, the great veins, the small vessels in every part of the body, especially in the mucous and serous membranes, the brain, liver, and kidneys, were strongly congested; and extravasations of blood were frequently found in the mucous and peritoneal coats of the bladder, and more rarely in the stomach and duodenum. The blood had a dark-red color, which became lighter on exposure to the air. Mitscherlich concluded that theobromine is poisonous in the same manner as caffeine, but

that it is poisonous and fatal in much smaller doses, and also that it is absorbed from the stomach as well as from the subcutaneous connective tissue.

Theobromine does not appear to have been used therapeutically, but the identity of its action with that of theine and caffeine renders it probable that it may be substituted for them in appropriate cases, but in smaller doses.

THERIACA, Br.—TREACLE.

Syrupus fuscus, U. S. 1870; *Sacchari fœc*, *Syrupus communis*, s. *hollandicus*.—*Molasses*, E.; *Mélasse*, *Pyromel*, Fr.; *Mélasse*, *Brauner Syrup*, G.

The uncrystallized residue of the refining of sugar.—Br.

Origin and Properties.—The manner in which molasses is obtained is described on page 1321. That variety procured in the preparation of raw sugar is in the United States usually designated as *West India molasses*, while that drained from refined sugar is known as *sugar-house molasses*. Both kinds closely resemble each other, except that the former is of a lighter color and has a different somewhat empyreumatic flavor. Molasses is a brown, thick, fermentable, uncrystallizable syrup of a very sweet taste and having a specific gravity of about 1.40. It contains about 75 per cent. of solid matter, of which from 5 to 7 per cent. are salts. The molasses of beet-root sugar, according to Landolt (1868), contains 56 to 64 per cent. of sugar and about 20 per cent. of oxalate, tartrate, and malate of potassium.

Medical Uses.—Molasses—or treacle, as it is called in England—is rather a food than a medicine. Apart from its pharmaceutical uses, it is seldom employed medicinally except as an ingredient of the common domestic enema, which consists usually of a pint of warm water to which a wine-glassful or more of molasses and a heaped tablespoonful of salt have been added. It is also a popular remedy for superficial *burns*, which it protects as well as oil.

THUJA, U. S.—THUJA (ARBOR VITÆ).

Thuya, *Arbre de vie*, Fr.; *Lebensbaum*, G.

The small branches of *Thuja occidentalis*, Linné.

Nat. Ord.—Coniferæ.

Origin.—The arbor vitæ, also called *white cedar*, is a tree with spreading branches, attaining under favorable circumstances a height of 50 feet (15 M.). It grows in cedar swamps in Canada and the northern section of the United States, and is met with southward along the Alleghanies and westward to Wisconsin. It has been introduced into Europe as an ornamental tree.

Description.—The branchlets are dark-green and rather glossy above, dull pale-green beneath, two-edged, and flat from the appressed scale-like leaves, which are placed in four rows, closely imbricate, $\frac{1}{8}$ to $\frac{1}{4}$ inch (3–4 Mm.) long, rhombic-ovate, obtusely pointed, and bear upon the back near the apex an elevated roundish gland; the leaves forming the edges of the branchlets are folded in the centre, compressed, boat-shaped, when young with a small gland beneath the apex, the older ones glandless. The odor is strongly balsamic and the taste pungently aromatic, camphoraceous, and bitter.

The allied *Thuja orientalis*, Linné, which is indigenous to Asia, is sometimes cultivated as an ornamental tree. It is distinguished from the preceding by the erect branches and by the absence of glands and the grooved back of the leaves. The Western species, *Thuja gigantea*, Nuttall, grows from Northern California northward, and attains a height of 120 feet (36 M.).

Constituents.—The volatile oil of arbor vitæ was examined by Bonastre (1825) and Schweizer (1844). Hübschmann (1846) obtained about 1 per cent. of the weight of the branchlets. The volatile oil is colorless or greenish-yellow, has the density 0.925, and is a mixture of two oxygenated oils boiling near 195° and 205° C. (383° and 400° F.); it is readily soluble in alcohol, and when treated with potassa or with sulphuric acid acquires a black color. Kawalier (1854–58) obtained from arbor vitæ, in addition to the volatile oil, a gelatinous compound, sugar, two resins, tannin, pinipicrin, and thujin. *Pinipicrin*, $C_{22}H_{36}O_{11}$, was discovered by Kawalier (1853) in the leaves and bark of *Pinus sylvestris*. It is a yellow bitter powder which becomes soft at 55° C. (131° F.), fuses to a transparent liquid at 100° C. (212° F.), is not precipitated by lead salts, dissolves in water, alcohol, and spirit of ether, is insoluble in pure ether, and when boiled with diluted acids is split into sugar and *ericiinol*. *Thujin*, $C_{20}H_{22}O_{12}$, crystallizes in small lemon-yellow

tables, has an astringent taste, dissolves readily in alcohol and hot water, acquires with alkalis a deep-yellow and red-brown and with ferric chloride a dark-green color, and is precipitated by acetate and subacetate of lead. When heated with dilute hydrochloric acid it is converted into sugar and *thujigenin*, $C_{14}H_{12}O_7$, and *thujetin*, $C_{14}H_{14}O_8$, both of which are almost insoluble in cold water, and when in alcoholic solution acquire a handsome blue-green color with ammonia. Thujin, boiled with hydrate of barium, yields sugar and *thujetic acid*, $C_{28}H_{22}O_{13}$, which is insoluble in water. These compounds are probably related to *quercitrin* and its derivatives.

Pharmaceutical Preparation.—*TINCTURA THUJÆ*. Tincture of arbor vitæ. 5 parts of the fresh small branches of arbor vitæ are bruised, and macerated with 6 parts of alcohol for 8 days; the liquid is expressed and filtered.—*P. G.* 1872. The tincture is of a greenish-yellow color.

Medical Action and Uses.—Arbor vitæ somewhat resembles savine in its qualities, and particularly by irritating the skin when the fresh leaves or an ointment made from them is applied to it. Like savine, it has been found useful in repressing the fungous granulations of *ulcers*, in removing *warts*, and in an ointment as a palliative of chronic *rheumatism*. Some have even gone so far as to attribute to it the cure of *cancerous* ulcers both of external parts and of the uterus. The published reports, however, rather denote cases of simple ulcers aggravated by improper applications as those which have been benefited by this medicine. Internally, it has been given with alleged benefit in *amenorrhœa* and *pulmonary catarrh*, and for destroying *worms*. For these several purposes the distilled oil has been found efficient. Boerhaave used a distilled water of the leaves in *dropsy*. A fluid extract and a saturated tincture have been given in *doses* of a fluidrachm (*Gm.* 4) several times a day, and applied topically on compresses and to the uterus on a tampon. An ointment made with the leaves or with the volatile oil has been used in rheumatism.

THUS AMERICANA, Br.—COMMON FRANKINCENSE.

The concrete turpentine of *Pinus Tæda*, *Linné*. (See *TEREBINTHINA*.)

Medical Uses.—This turpentine may be used for the various purposes to which other turpentines are adapted. In England it forms a constituent of the officinal pitch plaster, under the name of common frankincense.

THYMOL, U. S., Br., F. Cod.—THYMOL.

Thymolum, *P. G.*; *Acidum thymicum*.—*Thymol*, *E.*, *Fr.*, *G.*; *Thymic acid*, *E.*; *Acide thymique*, *Fr.*; *Thymiansäure*, *G.*

Formula $C_{10}H_{14}O$. Molecular weight 150.

Origin.—Thymol is present in the volatile oils of *Thymus vulgaris*, *Linné*, *Monarda punctata*, *Linné*, and *Ptychotis Ajowan*, *De Candolle*, and very likely in other volatile oils of the natural orders Labiatae and Umbelliferae.

Preparation.—Oil of thyme is subjected to fractional distillation. That portion which distils at a temperature above $200^{\circ} C.$ ($392^{\circ} F.$) is separately collected, and is agitated with solution of soda, the solution of thymol sodium separated from the thymene, and the thymol liberated by hydrochloric acid; after it has crystallized it is pressed between bibulous paper and recrystallized from alcohol. This is *Lallemand's process* (1853), which may be modified so as to distil off only the hydrocarbons at a temperature not exceeding $180^{\circ} C.$ ($356^{\circ} F.$), and treating the residue in the still with soda solution as stated. By a similar process thymol is obtained from the volatile oils of *Monarda* and of *Ptychotis*.

Properties.—Thymol crystallizes in thin, colorless, rhombic scales or is seen in commerce in large translucent crystals of the spec. grav. 1.028. It melts between 50° and $52^{\circ} C.$ (122° – $125.6^{\circ} F.$) (*U. S.*, *P. G.*) to a colorless liquid lighter than water, retains its fluid condition often for a long time, and boils near $230^{\circ} C.$ ($446^{\circ} F.$). It has an aromatic thyme-like odor and a warm, pungent but scarcely caustic taste. It dissolves sparingly in water, requiring at $15^{\circ} C.$ 1100 (*P. G.*) or 1200 (*U. S.*) parts for solution, but is soluble in half its weight of alcohol, ether, and chloroform, in 2 parts of soda solution sp. gr. 1.16, and freely in benzol, benzin, carbon disulphide, glacial acetic acid, and fixed and volatile oils. It forms with soda a crystallizable and readily soluble compound, and does not change the color of solution of ferric chloride. Symes (1879) ascertained that on being triturated with one-half to ten times its weight of camphor a colorless syrupy

liquid is obtained, but it does not liquefy with chloral hydrate. According to Gerrard, the strongest aqueous solution of thymol available is 1 in 1000, and a solution of 4 grains of it in a fluidounce of alcohol is miscible with water without becoming turbid; 3 grains of thymol are dissolved by 1 grain of caustic soda and 1½ grains of caustic potassa. Solid fats, when heated, are excellent solvents of thymol. A solution of 1 part of thymol in 100 parts of warm glycerin remains clear. Thymol is also soluble in 4 parts of cold sulphuric acid; the solution has a yellowish color, and on being gently heated becomes rose-red. On pouring this solution into 10 volumes of water, digesting the mixture with an excess of lead carbonate, and filtering, the liquid becomes violet-blue on the addition of ferric chloride. This reaction is due to *sulphothymolic acid*, $C_{10}H_{14}SO_4$, discovered by Lallemand (1853). Hammarsten and Robert (1881) give the following as the most delicate test by which one-millionth of thymol may still be detected: Mix the liquid with one-half of its volume of glacial acetic acid, then with at least an equal volume of sulphuric acid, and warm gently, when a bright reddish-violet color is produced which is not destroyed by boiling. According to Hirschsohn (1881), a solution of thymol in 60,000 parts of water is rendered turbid by bromine-water, but, according to Hammarsten, the precipitate is not crystalline like tribromophenol.

Composition.—Thymol is the phenol of cymene, and its composition is shown by the formula $C_6H_3.C_3H_7.CH_3.OH$. Widman (1882) has succeeded in preparing it synthetically from cuminol (see page 524) by converting this into nitrocuminol, acting upon this with phosphorus pentachloride, when nitrocymylene chloride, $C_{10}H_{11}(NO_2)Cl_2$, is formed, and treating this with nascent hydrogen, first at a low temperature, afterward with the aid of heat, to obtain cymidin, $C_{10}H_{13}.NH_2$. A dilute solution of cymidin sulphate is treated with potassium nitrite and finally distilled, when thymol is obtained, having the melting-point $44^\circ C.$ ($111.2^\circ F.$), which is the same as found by Lallemand and Stenhouse for thymol from the oils of thyme and of pyctotis. Widman prepared nitrosothymol from artificial thymol; the product from both fused between 160° and $162^\circ C.$ (320° – $323.6^\circ F.$).

Tests.—Thymol should be volatilized by the heat of a water-bath without leaving any residue (inorganic and non-volatile organic compounds). Its saturated aqueous solution should have a neutral reaction, and should not acquire a darker color on the addition of a drop of test solution of ferric chloride (carbolic acid, various phenols, etc.).

Action and Uses.—These have been considered under *OLEUM THYMI*.

TILIA.—LINDEN.

Flores tilieæ, P. G.—*Linden-flowers*, E.; *Fleurs de tilleul*, Fr.; *Lindenblüthen*, G.

The inflorescence of different species of *Tilia*.

Nat. Ord.—Tiliaceæ.

Origin.—The different species of linden, which are also known as *lime tree*, *white-wood*, and *bass-wood*, are stately trees from 40 to 100 feet (12–30 M.) high, and have a soft white wood, a fibrous bark, and alternate petiolate, heart-shaped, serrate leaves, frequently with a more or less oblique base. The wood yields a very light charcoal.

TILIA ULMIFOLIA, *Scopoli* (*T. parvifolia*, *Ehrhart*, *T. microphylla*, *Ventenat*). The leaves are pale-green on the lower surface and pubescent in the angles of the veins, otherwise smooth; the cymes are about seven-flowered.

TILIA PLATYPHYLLOS, *Scopoli* (*T. grandifolia*, *Ehrhart*, *T. pauciflora*, *Hayne*). The leaves are larger and softly pubescent beneath; the cymes are about three-flowered. This, with the preceding species, constitutes *Tilia europæa*, *Linneé*, and is occasionally cultivated as an ornamental tree.

TILIA AMERICANA, *Linneé*. It has thickish and smooth (*T. glabra*, *Ventenat*) or underneath softly pubescent and frequently thin (*T. pubescens*, *Aiton*) leaves; the cymes are mostly many-flowered. The smooth form grows in Canada and the United States, the pubescent variety from Maryland southward.

TILIA HETEROPHYLLA, *Ventenat* (*T. alba*, *Michaux*, *T. laxiflora*, *Pursh*). It is found from the mountains of Pennsylvania along the Ohio and Mississippi and southward, and has the leaves bright-green and smooth above and silvery-whitened beneath. It resembles the South European *Tilia argentea*, *Desfontaines*, which, however, has the leaves on shorter petioles.

Description.—Linden-flowers grow in axillary cymes, and have the peduncle partly united to the midrib of a leaf-like, linear, or oblong-lanceolate greenish-yellow bract. The flowers of each cyme vary in the different species from three to about thirty in num-

ber, and have a five-parted calyx and five whitish or yellowish, lanceolate or oblong, usually notched petals. The numerous stamens are hypogynous, slightly united in the first two species by the base of their filaments into about five groups, or in the other species with the base of a petal-like scale placed opposite each petal. The ovary is five-celled, has a style with a five-lobed stigma, and produces a globular, nut-like, one-celled capsule containing one or two seeds. Linden-flowers have an agreeable and (when dry) feeble odor and a sweetish and mucilaginous taste. American linden-flowers and their bracts are larger than the European, and the petals have a somewhat horn-like appearance.

Constituents.—From the analyses made by Marggraf, Brossat, Buchner, Siller, Winckler, and others, it appears that linden-flowers contain mucilaginous or pectinaceous principles, sugar, a little tannin, fat, malates and other salts. The odorous principle is a colorless or yellowish, sweetish, light, and fragrant volatile oil, which is readily soluble in alcohol and dissolves iodine without giving off vapors. Herberger and Winckler obtained between $\frac{1}{20}$ and $\frac{1}{10}$ per cent.

Pharmaceutical Preparation.—AQUA TILLÆ, Linden-flower water. Distil 1 part of linden-flowers and sufficient water until 4 parts (10 parts, *P. G.* 1872) of distillate are obtained.—*F. Cod.*

Allied Plants.—CORCHORUS CAPSULARIS, C. OLITORIUS, *Linne*, and several other species are annual herbs of India, where they are cultivated for their bast-fibres, which are known in commerce as *gunny* and *jute*; the fibre yields from 1 to 2 per cent. of ash. The second species is also employed as a potherb.

Medical Uses.—On the continent of Europe linden-flowers, buds, and leaves are among the most generally used of domestic remedies, in the form of an infusion, to palliate *painful indigestion, nervousness, nervous headache*, and even mild forms of *hysteria*. For these purposes it is taken either cold or warm, according to circumstances, but in the latter way to dissipate commencing *catarrhs of the respiratory passages and diarrhæa* occasioned by cold. The flowers are also used in warm general baths to allay nervous irritability, or a strong infusion of them is administered by enema for similar purposes. The American species is probably quite as operative as the European, and both depend for whatever virtues they possess upon their combined lenitive and stimulant qualities. The agreeable smell and taste of the infusion render it acceptable to the sick and appropriate as a vehicle for more active medicines. The infusion is usually made with from 30 to 60 grains of the flowers to a pint (Gm. 2-4 to Gm. 500) of water.

TINCTURÆ.—TINCTURES.

Teintures, Alcoolés, Fr.; Tinkturen, G.

Tinctures are solutions of medicinal non-volatile or only partially volatile substances in liquids other than water and glycerin. Solutions of volatile substances in water are known as *medicated waters*, and similar solutions in alcohol as *spirits*. The menstrua employed in the preparation of tinctures are alcohols of different strengths, spirit of ether or spirit of nitrous ether, and aromatic spirit of ammonia or ammoniated alcohol. According to the menstruum employed, tinctures are distinguished as *ammoniated, ethereal, and alcoholic*, and that class of tinctures in the preparation of which diluted alcohol or a still weaker spirit has been used is sometimes designated as *hydro-alcoholic*. By far the greatest number of tinctures are made with an alcoholic menstruum. The employment of spirit of nitrous ether in tinctures is confined to a few unofficial preparations.

Alcoholic Menstruum.—Most tinctures of the United States Pharmacopœia are prepared with diluted alcohol, of the British Pharmacopœia with proof spirit, and of the French and German Pharmacopœias with alcohol of about 60 per cent., or of specific gravities 0.912 and 0.894. While it is desirable to keep the alcoholic strength of tinctures as low as possible, it is evidently improbable that one and the same menstruum should be equally well adapted for the preservation of liquid preparations of drugs having the most varied composition; and that improvements in this respect are needed is shown by the unsightly deposits occurring in some and the change into gelatinous masses observed in other tinctures. In most cases these obvious changes are prevented by the employment of a stronger alcoholic menstruum.

Strength.—The British Pharmacopœia prepares tinctures in such a manner that 1 Imperial pint (20 fluidounces) represents $2\frac{1}{2}$ oz. av. of the drug, or 1 part of the drug is

used for 8 measured parts of the finished tincture; the U. S. P. 1870 recognized a similar proportion—1 troyounce of drug to 8 fluidounces of tincture. There are, however, numerous important exceptions to this rule, and notably among tinctures of narcotic and other powerful drugs. The present U. S. P. directs tinctures, like all other liquid preparations (fluid extracts excepted), to be prepared by weight; and in making this change of manipulation the previous strength of the tinctures has been preserved as nearly as possible. The French and German Pharmacopœias prepare their tinctures almost without exception in such a manner that 1 part of the drug is represented by about 5 or 10 parts (by weight) of the tincture, either 5 or 10 parts of the menstruum being used for extracting 1 part of the drug by maceration. Prepared in this manner, the actual weight of the tincture is equal to that of the menstruum and of the soluble matter combined, so that the strength is only approximately as 1 in 5 or 10.

It is to be regretted that the tinctures of the different pharmacopœias, or at least those prepared from potent drugs, are not of the same composition, as will be seen from the following table, in which no account is taken of the difference in the density of the menstruum:

100 parts of tincture of—	Represent parts of the active drug—				100 parts of tincture of—	Represent parts of the active drug—

Preparation.—Tinctures of resins, oleoresins, balsams, and of most gum-resins and extractive drugs are best prepared by maceration. Nearly all other drugs are conveniently extracted by percolation, which process is fully described on pages 606, etc., and if the process is properly conducted the drug will be practically exhausted long before the requisite amount of tincture has been obtained. The chief objections that can be raised against this process are, that the manipulation must vary with the nature of the drug, and that a certain amount of alcohol will be retained in the powder. The former is of no weight with the pharmacist, who recognizes his duty of intimately acquainting himself with the characteristics and peculiarities of each drug passing through his hands; and the second objection will be of little moment if weaker menstrua are gradually and judiciously employed, as indicated on page 608. In the formulas which follow the “parts” directed by the Pharmacopœia have been rendered in convenient weights, and the approximate measure has been given for each preparation. This measure necessarily varies somewhat with the temperature and with the amount of solid matter taken up from the drug; but it serves a convenient purpose in indicating when the percolate has nearly attained the desired weight, thus avoiding frequent weighings. The tare of the receiving vessel is accurately taken and marked on the paper indicating the approximate measure to be obtained, after which percolation may proceed and be finished with little trouble.

The British Pharmacopœia avoids the second objection by expressing the contents of the percolator as soon as the requisite quantity of menstruum has been used. In most of its formulas the preparation of a pint (Imperial) of tincture is directed, and the following explains the manipulations which have been adopted: Macerate the material for 48

hours in 15 fluidounces of the menstruum in a closed vessel, agitating occasionally; then transfer to a percolator and when the fluid ceases to pass continue the percolation with the remaining 5 ounces of menstruum. Afterward subject the contents of the percolator to pressure, filter the product, mix the liquids, and add sufficient menstruum to make 1 pint.

The German Pharmacopœia prepares all tinctures by maceration. The drugs, either coarsely powdered or cut into thin slices, and the menstruum are introduced into a bottle, which should be only partly filled, so as to permit the frequent agitation of the contents; after macerating in a shady place at about 15° C. (59° F.) for a week, the liquid is decanted and the residue subjected to pressure; the liquids thus obtained are mixed, set aside for a day or two, and then filtered, care being taken to prevent the evaporation of alcohol. The liquid which remains absorbed in the drug is not replaced.

The French Codex directs its tinctures to be made by maceration or by displacement. For the latter process the directions are similar to those of the United States Pharmacopœia, except that the powder is ordered to be of medium fineness and is not moistened previously to its introduction into the percolator.

ETHEREAL TINCTURES—*Éthérolés, F. Cod.*—are not recognized by the U. S. P., and only one has been admitted by the Br. P. (*lobelia*) and by the P. G. (*valeriana*), both using spirit of ether for the menstruum. For eight ethereal tinctures of the French Codex a menstruum containing more ether is used; it is designated *Ether à 0.758*, and is prepared by mixing 3 parts of alcohol with 7 parts of ether spec. grav. .724. These tinctures are prepared by maceration or displacement, provision being made to prevent evaporation of the ether.

Preservation.—All tinctures should be perfect solutions, and to retain them entirely transparent the evaporation of the volatile portions should be prevented. Tinctures are best kept in well-stoppered bottles, in a room where the temperature is not subject to great variations, and where they are not exposed to the direct sunlight. The size of the bottles should be adapted to the quantities of the tincture that are likely to be used within a reasonable length of time.

TINCTURÆ HERBARUM RECENTIUM, U. S.—TINCTURES OF FRESH HERBS.

Alcoolaturæ, F. Cod.—*Alcoolatures, Fr.; Tinkturen von frischen Pflanzen, G.*

Tinctures made from fresh herbs were, to some extent, prepared more than two hundred years ago, but were more prominently introduced by Hahnemann, and are extensively employed in homœopathic practice. They have attracted more or less attention in Europe since about 1817, when Schrader (*Buchner's Repertorium*, iii. 20) made a number of investigations, and recommended such tinctures prepared from the fresh juice and twice its weight of alcohol. A similar method was subsequently advocated by Béral and by Deschamps, while Soubeiran suggested the use of the fresh plants and their maceration with strong alcohol in definite proportions. This method was adopted in the French Codex of 1866, and has been retained in that of 1884. Tinctures made from fresh herbs have been admitted in the new U. S. Pharmacopœia, which, however, gives only a general formula.

Preparation.—"These tinctures, when not otherwise directed, are to be prepared by the following formula: Take of the fresh herb, bruised or crushed, 50 parts; alcohol 100 parts. Macerate the herb with the alcohol for fourteen days; then express the liquid and filter."—*U. S.*

This is essentially the formula for preparing the third class of tinctures of the Homœopathic Pharmacopœia. The French Codex directs equal parts of the fresh drug and of 90 per cent. alcohol, the maceration to be continued for ten days; in this manner alcoolatures are prepared from *aconite-leaves* and *root*, *arnica-flowers*, *belladonna-leaves* and *root*, *bryony*, *colchicum-flowers* and *root*, *conium-leaves*, *digitalis-leaves*, *drosera* (entire plant), *eucalyptus-leaves*, *hyoscyamus-leaves*, *pulsatilla* (flowering herb), *spilanthes-flowers*, and *stramonium-leaves*.

It is evident that these preparations must vary in strength at least to the same extent as juices (see p. 1452), and that they are of doubtful utility, except perhaps for such drugs which, like the leaves of *Rhus Toxicodendron*, owe their virtues to very volatile uncombined principles.

TINCTURA ACONITI, U. S., Br., P. G.—TINCTURE OF ACONITE.

Tinctura aconiti radicis, U. S. P. 1870.—*Tincture of aconite-root*, E.; *Teinture de racine d'aconit*, Fr.; *Eisenhuttinktur*, G.

Preparation.—Aconite, in No. 60 powder, 400 parts (12 oz. av.); Tartaric Acid 4 parts (52½ grains); Alcohol a sufficient quantity; to make 1000 parts (30 oz. av.). Moisten the powder with 200 parts (6 oz. av. or 7 fluidounces) of alcohol in which the tartaric acid has previously been dissolved, and macerate for 24 hours; then pack it firmly in a cylindrical glass percolator, and gradually pour alcohol upon it until 1000 parts (30 oz. av. or about 34 fluidounces) of tincture are obtained.—*U. S.*

Aconite-root 2½ oz. av., alcohol (sp. gr. .838) sufficient to make 1 Imperial pint (20 fluidounces).—*Br.*

Aconite-root 20 parts, alcohol (sp. gr. .912) 100 parts.—*F. Cod.*

Aconite-root 10 parts, alcohol (sp. gr. .894) 100 parts.—*P. G.*

There is no obvious necessity for the use of tartaric acid in the first formula, but the selection of efficient root and its careful percolation are of the utmost importance. The tincture is of a yellowish-brown color, and on the addition of water becomes milky from the precipitation of resin. Formerly *tincture of aconite-leaves* (2 troyounces to 1 pint of diluted alcohol) was official; it was much weaker than the present tincture, and could be given in larger doses.

Medical Uses.—Tincture of aconite is the best form for the administration of this powerful medicine. The *dose* is from 1 to 5 minims (Gm. 0.06–0.30).

TINCTURA ALOES, U. S., Br., P. G.—TINCTURE OF ALOES.

Teinture d'aloès, Fr.; *Aloetinktur*, G.

Preparation.—Purified Aloes, in moderately fine powder, 10 parts (1 oz. av.); Extract of Glycyrrhiza, in moderately fine powder, 10 parts (1 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (10 oz. av.). Mix the powders with 80 parts (8 oz. av. or 8½ fluidounces) of diluted alcohol, and macerate the mixture for 7 days in a closed vessel; then filter through paper, adding, through the filter, enough diluted alcohol to make the tincture weigh 100 parts (10 oz. av. or about 10 fluidounces).—*U. S.*

The formulas of other pharmacopœias require—Socotrine aloes ½ ounce, extract of liquorice 1½ ounces (av.), proof spirit sufficient for 1 pint (Imperial).—*Br.* Aloes 1 part, alcohol (sp. gr. .912) 5 parts.—*F. Cod.* Aloes 1 part, alcohol (sp. gr. .832) 5 parts.—*P. G.*

The tincture has a dark blackish-brown color and a very bitter taste.

Medical Uses.—This preparation is rarely used as a purgative, for which purpose not less than half an ounce (Gm. 16) of it would be necessary. As a laxative 1 or 2 fluidrachms (Gm. 4–8) may be taken after food. It has been applied topically as a dressing for indolent ulcers, excoriations, bed-sores, fissures, and cutaneous eruptions. It enters into various preparations of old repute for their virtues in such affections—*e. g.* Turlington's balsam, Friars' balsam, etc.—and has more recently been employed for similar purposes with glycerin, by evaporating from 4 to 8 parts of the tincture of aloes, and then gradually adding 30 parts of glycerin.

TINCTURA ALOES ET MYRRHÆ, U. S.—TINCTURE OF ALOES AND MYRRH.

Elixir proprietatis Paracelsi.—*Elixir de propriété*, Fr.; *Aloëelixir*, G.

Preparation.—Purified Aloes, in moderately fine powder, 10 parts (1 oz. av.); Myrrh, in moderately fine powder, 10 parts (1 oz. av.); Alcohol a sufficient quantity; to make 100 parts (10 oz. av.). Mix the powders with 80 parts (8 oz. av. or 8½ fluidounces) of alcohol, and macerate the mixture for 7 days in a closed vessel; then filter through paper, adding, through the filter, enough alcohol to make the tincture weigh 100 parts (10 oz. av. or about 10 fluidounces).—*U. S.*

This preparation has been dropped from the other pharmacopœias; that of the P. G. 1872 was four-fifths of the above strength and contained also 4 per cent. of saffron and 8 per cent. of diluted sulphuric acid sp. gr. 1.115.

The color of this tincture is deep reddish-brown; if prepared with saffron it is of a rich orange-brown. It is precipitated by water.

In this connection should be mentioned the following preparation, which has long enjoyed considerable reputation on the continent of Europe:

TINCTURA ALOES COMPOSITA, *P. G.*; Elixir ad longam vitam, Elixir succicum.—Compound tincture of aloes, Swedish bitters, *E.*; Elixir de longue vie, Elixir suédois, *Fr.*; Lebenselixir, *G.*—Aloes 6 parts, and gentian, rhubarb, zedoary, and saffron, each 1 part, are macerated for a week with 200 parts of alcohol sp. gr. .894; the tincture is expressed and filtered.—*P. G.* The formula of the French Codex reduces the aloes to 4 parts, the other ingredients to $\frac{1}{2}$ part, and adds $\frac{1}{2}$ part each of agaric and of confection of opium.

Medical Uses.—As a purgative capable of especially stimulating the pelvic organs this preparation has been employed under the name of *Elixir proprietatis* ever since it was invented by Paracelsus, and also as peculiarly fitting for *constipation* in females when associated with *amenorrhœa* or irregular menstruation. But this state is commonly a result of general atony, and can only be radically cured by remedies addressed to the general system. The *dose* is from 1 to 2 fluidrachms (*Gm.* 4–8).

TINCTURA ARNICÆ FLORUM, *U. S.*—TINCTURE OF ARNICA- FLOWERS.

Tinctura arnicæ, *U. S. P.* 1870, *P. G.*—*Teinture de fleur d'arnica*, *Fr.*; *Arnikatinktur*, *G.*

Preparation.—Arnica-Flowers, in No. 20 powder, 20 parts (6 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 40 parts (12 oz. av. or $12\frac{1}{2}$ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—*U. S.*

Arnica-flowers 20 parts, alcohol (sp. grav. .912) 100 parts.—*F. Cod.*

Arnica-flowers 10 parts, alcohol (sp. grav. .894) 100 parts.—*P. G.*

The first formula yields a yellowish-brown tincture of a darker tint than the other two and that of the *U. S. P.* 1870, a less alcoholic menstruum being now employed, which extracts more of the extractive matter, but probably less of the resinous and oily constituents. The present tincture becomes less opalescent with water than one prepared with a stronger alcoholic menstruum.

Medical Uses.—In Germany tincture of arnica is universally employed as the sovereign domestic remedy for *wounds*, *bruises*, and all manner of *local pains*, which it benefits quite as much through the alcohol as through the essential oil that it contains. It is applied diluted with water as a lotion or upon compresses; it is not often prescribed internally, but may be given in *doses* of from 10 to 60 drops (*Gm.* 0.60–4).

TINCTURA ARNICÆ RADICIS, *U. S.*—TINCTURE OF ARNICA-ROOT.

Tinctura arnicæ, *Br.*; *Teinture de racine d'arnica*, *Fr.*; *Arnikawurzel tinktur*, *G.*

Preparation.—Arnica-Root, in No. 40 powder, 10 parts (3 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 10 parts (3 oz. av. or $3\frac{1}{2}$ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—*U. S.*

Arnica-root 1 oz. av., alcohol (sp. gr. .838) sufficient to make 1 Imperial pint (20 fluidounces).—*Br.*

The first formula yields a darker-colored tincture than the second, due not merely to the larger amount of drug used, but on account of the reduced alcoholic strength of the menstruum, which is the same as that used for the fluid extract.

Action and Uses.—The German Pharmacopœia does not contain any tincture of arnica-root, and it is difficult to understand why the American should be so encumbered. The *dose* may be stated as about the same as that of the tincture of the flowers.

TINCTURA ASAFÆTIDÆ, *U. S., Br.*—TINCTURE OF ASAFETIDA.

Tinctura asæ fætidæ, *P. G.*—*Teinture d'asafetida*, *Fr.*; *Asantinktur*, *G.*

Preparation.—Asafetida, bruised, 20 parts (6 oz. av.); Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Mix the asafetida with 80 parts (24 oz. av. or 28 fluidounces) of alcohol, and macerate for 7 days in a closed vessel; then filter through

paper, adding, through the filter, enough alcohol to make the tincture weigh 100 parts (30 oz. av. or about 33 fluidounces).—*U. S.*

The proportions of other pharmacopœias are—*Asafetida* 2½ oz. av., rectified spirit sufficient for 1 pint (Imperial).—*Br.* *Asafetida* 1 part, alcohol 5 parts.—*F. Cod.*, *P. G.*

The tincture is about one-third stronger than that of the *U. S. P.* 1870, and nearly agrees with those of the French and German Pharmacopœias. It has a yellowish brown-red color and is rendered milky on the addition of water.

Off. Prep.—*Mistura magnesiae et asafetida*, *U. S.*

TINCTURA ÆTHEREA ASAFETIDÆ. *Asafetida* 2 parts, ether 7 parts, alcohol 3 parts.—*F. Cod.*

Medical Uses.—Owing to its repulsive taste, tincture of *asafetida* is seldom given by the mouth, although the *dose* is commonly stated to be from 30 minims to a fluidrachm (*Gm.* 2–4). It is more convenient and useful in an enema, with water alone, or with other appropriate adjuncts, for the relief of intestinal flatulence and for obtaining the influence of the drug in hysterical attacks. From ½ to 1 fluidounce (*Gm.* 16–32) may be used in this manner.

TINCTURA AURANTII AMARI, *U. S.*—TINCTURE OF BITTER ORANGE-PEEL.

Tinctura aurantii, *U. S.* 1870, *Br.*—*Tincture of orange-peel*, *E.*; *Teinture d'orange amère*, *Fr.*; *Pomeranzentinktur*, *G.*

Preparation.—Bitter Orange-Peel, in No. 30 powder, 20 parts (6 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 20 parts (6 oz. av. or 6½ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it moderately in a conical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—*U. S.*

Other pharmacopœias direct: Bitter orange-peel 2 ounces (av.), proof spirit sufficient for 1 pint (Imperial).—*Br.* Bitter orange-peel 1 part; macerate with 5 parts of alcohol spec. grav. .863.—*F. Cod.* (spec. grav. .894, *P. G.*).

The tincture has a yellowish-brown color, and is about one-fourth stronger than that of the *U. S. P.* 1870.

Off. Prep.—*Mistura ferri aromatica*, *Syrupus aurantii*, *Tinct. quiniæ*, *Br.*

Medical Uses.—Tincture of bitter orange-peel is employed almost exclusively as a flavoring ingredient in mixtures. The *dose* is 1 to 2 fluidrachms (*Gm.* 4–8).

TINCTURA AURANTII DULCIS, *U. S.*—TINCTURE OF SWEET ORANGE-PEEL.

Teinture d'orange douce, *Fr.*; *Apfelsinentinktur*, *G.*

Preparation.—Sweet Orange-Peel, recently separated from the fresh fruit and deprived of the inner white layer, 20 parts (6 oz. av.); Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Mix the orange-peel, previously cut into small pieces, with 80 parts (24 oz. av. or 28 fluidounces) of alcohol, and macerate for 24 hours; then pack it moderately in a conical percolator, and gradually pour alcohol upon it until 100 parts (30 oz. av. or about 34 fluidounces) of tincture are obtained.—*U. S.*

By careful grating the yellow rind of fresh oranges is easily removed, and at once obtained in a suitable condition for preparing the tincture, which has a yellow color and a very agreeable odor.

TINCTURA AURANTII RECENTIS, *Br.*—TINCTURE OF FRESH ORANGE-PEEL.

Preparation.—Take of Bitter Orange, Rectified Spirit, each a sufficiency. Carefully cut from the orange the colored part of the rind in thin slices, and macerate 6 ounces of this in 18 fl. oz. of the spirit for a week, with frequent agitation. Then pour off the liquid, press the dregs, mix the liquid products, and filter; finally, add sufficient spirit to make 1 pint (Imperial).—*Br.*

Medical Uses.—The tincture of fresh orange-peel contains a larger proportion of the volatile oil and has a more agreeable flavor than that made from the dry rind of the bitter orange. The *dose* is 1 or 2 fluidrachms (*Gm.* 4–8).

TINCTURA BELLADONNÆ, U. S., Br.—TINCTURE OF BELLADONNA.*Teinture de belladone*, Fr.; *Belladomatinktur*, G.

Preparation.—Belladonna-Leaves, in No. 60 powder, 15 parts (4½ oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 20 parts (6 oz. av. or 6½ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—*U. S.*

The proportions directed by other pharmacopœias are—Belladonna-leaves 1 ounce (av.), proof spirit sufficient for 1 pint (Imperial).—*Br.* Belladonna-leaves 1 part, alcohol (sp. gr. .912) 5 parts.—*F. Cod.*

This tincture differs very little in strength from that of the U. S. P. 1870. The color is greenish-brown or brown-green, according to the strength of the alcohol.

TINCTURA ÆTHEREA BELLADONNÆ. Belladonna-leaves 2 parts, ether 7 parts, alcohol 3 parts.—*F. Cod.*

Medical Uses.—The *dose* of this tincture is about 7 minims, representing 1 grain of the leaves (Gm. 0.50).

TINCTURA BENZOINI, U. S.—TINCTURE OF BENZOIN.*Tinctura benzoës*, P. G.—*Teinture de benjoin*, Fr.; *Benzoëntinktur*, G.

Preparation.—Benzoin, in moderately coarse powder, 20 parts (6 oz. av.); Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Mix the powder with 80 parts (24 oz. av. or 28 fluidounces) of alcohol, and macerate for 7 days in a closed vessel; then filter through paper, adding, through the filter, enough alcohol to make the tincture weigh 100 parts (30 oz. av. or about 32 fluidounces).—*U. S.*

Macerate benzoin 1 part in alcohol 5 parts.—*F. Cod., P. G.*

The tincture is brownish-red, and yields with water a milky mixture having an acid reaction.

LAC VIRGINIS—Virgin's milk, *E.*; *Lait virginal*, *Fr.*; *Jungfernmileh*, *G.*—is a cosmetic preparation consisting of tincture of benzoin 1 part and rose-water from 20 to 100 parts.

Medical Uses.—The tincture of benzoin was formerly in more general use than at present, both internally and externally. By the former method it was employed in chronic mucous profluvia of the *bronchial* and *urinary organs*, and even in chronic *diarrhœa* and *dysentery*; in the same cases, in short, for which *copaiba* has more recently been recommended. As a local application by means of the atomizer it may sometimes be administered with benefit in chronic *laryngeal* and *bronchial catarrh*. Externally, it is useful both as a stimulant and a protective for *ulcers*, and even for slight *fresh wounds*. But it is more applicable to irritable and indolent sores, as *bed-sores*, ulcers tending to gangrene, *sore nipples*, *chapped hands* and *lips*, and to slight lesions of the same sort about the *anus*. Mixed with water or rose-water, it may be used to remove *freckles* and slight *papular* and other *eruptions*, as well as to preserve the freshness and suppleness of the skin. It is the medicinal ingredient of the usual forms of court plaster, and too often renders this preparation irritating rather than healing. The *dose* of tincture of benzoin is from 30 minims to a fluidrachm (Gm. 2–4).

TINCTURA BENZOINI COMPOSITA, U. S., Br.—COMPOUND TINCTURE OF BENZOIN.

Tinctura balsamica, F. Cod.; *Balsamum commendatoris*, *Elixir traumaticum*.—*Teinture balsamique*, *Baume du commandeur de Permes*, F.; *Persischer Wundbalsam*, G.

Preparation.—Benzoin, in coarse powder, 12 parts (3 oz. av.); Purified Aloes, in coarse powder, 2 parts (½ oz. av.); Storax 8 parts (2 oz. av.); Balsam of Tolu 4 parts (1 oz. av.); Alcohol a sufficient quantity; to make 100 parts (25 oz. av.). Mix the benzoin, aloes, storax, and balsam of Tolu with 75 parts (18¾ oz. av. or 22 fluidounces) of alcohol, and macerate the mixture for 7 days in a closed vessel; then filter through paper, adding, through the filter, enough alcohol to make the tincture weigh 100 parts (25 oz. av. or about 26 fluidounces).—*U. S.*

Take of benzoin, in coarse powder, 2 ounces; prepared storax 1½ ounces; balsam of Tolu ½ ounce (av.); Socotrine aloes 160 grains; rectified spirit sufficient for 1 pint (Imperial). Macerate for 7 days and filter.—*Br.*

St. Johnswort 2 parts; angelica-root, myrrh, olibanum and aloes, of each 1 part; balsam of Tolu and benzoin, of each 6 parts; alcohol (spec. grav. .863) 72 parts.—*F. Cod.*

The older pharmacopœias had still more complicated formulas.

The tincture is intended to take the place of numerous preparations formerly employed, as *Wade's*, *Verrain's*, *Saint Victor's*, *Jesuits'*, *Friars'*, *Turlington's*, *Persian*, and *Swedish balsam*. It is of a deep red-brown color, and yields with water a reddish-white opaque mixture having an acid reaction.

Medical Uses.—The uses of the compound tincture are essentially the same as those of the simple tincture of benzoin, but the former is in most cases the more efficient of the two. Especially is this true of its use in affections of the air-passages and lesions of the skin. For such ailments it was for centuries in high repute under various names, as *Friars' balsam*, *Turlington's balsam*, etc., until it was displaced by the influence of doctrinal principles in therapeutics. Those who considered the cure of disease of more consequence than the justification of a doctrine adhered to its use, and the medicine survived the theory. It is needless to particularize all the cases in which this preparation may be beneficially used; they are, as already stated, those mentioned under the head of the simple tincture. The *dose* is from 30 minims to a fluidrachm (Gm. 2–4).

The compound is far more efficient than the simple tincture as an application to the various ulcerative lesions mentioned in the article upon that preparation, and especially to *bed-sores*. After cleansing and drying the sore it should be thoroughly covered with the tincture, over which should be laid two thicknesses of fresh cotton wadding extending far beyond the sore, and the whole supported by a broad bandage. The application is for a short time painful, but it should be removed at intervals of two or more days, care being taken at each dressing to remove any dead tissue that is loose (Woodman).

TINCTURA BRYONIÆ, U. S.—TINCTURE OF BRYONIA.

Teinture de bryone blanche, Fr.; *Zaunrüben tinktur*, G.

Preparation.—Bryonia, recently dried and in No. 40 powder, 10 parts (3 oz. av.); Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 10 parts (3 oz. av. or $3\frac{1}{2}$ fluidounces) of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it until 100 parts (30 oz. av. or about 34 fluidounces) of tincture are obtained.—*U. S.*

This tincture is not recognized by the other pharmacopœias; it has a brown-yellow color, is destitute of any characteristic odor, and has a somewhat bitter taste. Since bryony does not grow in North America, it will be difficult to comply with the pharmacopœial directions of using the “recently-dried” root. The bitter principle, bryonin, is soluble in water: hence diluted alcohol would seem to be an equally effective menstruum.

Action and Uses.—This drastic purgative may be prescribed in *doses* of from 15 to 60 drops (Gm. 1–4).

TINCTURA BUCHU, Br.—TINCTURE OF BUCHU.

Teinture de buchu, Fr.; *Buchutinktur*, G.

Preparation.—Take of Buchu-Leaves, in No. 20 powder, $2\frac{1}{2}$ ounces (av.); Proof Spirit 1 pint (Imperial). Prepare the tincture by maceration, as described under TINCTURÆ.—*Br.* Buchu 1 part, alcohol (sp. gr. .836) 5 parts.—*F. Cod.*

The first tincture has a greenish-brown, the second a brownish-green, color; both have the odor and taste of the drug.

Medical Uses.—A medicine intended to allay irritated conditions of the urinary passages should seldom be prepared with alcohol, or if it is so it should be administered in a large proportion of water. The convenience of dispensing buchu under certain circumstances may justify this preparation, but on purely therapeutical grounds it is ineligible. The *dose* of the tincture is 1 or 2 fluidrachms (Gm. 4–8).

TINCTURA CALENDULÆ, U. S.—TINCTURE OF CALENDULA.

Tincture of marigold, E.; *Teinture de souci*, Fr.; *Calendulatinktur*, G.

Preparation.—Calendula, in No. 20 powder, 20 parts (6 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 40 parts

(12 oz. av. or 12½ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 30 fluidounces) of tincture are obtained.—*U. S.*

This, like *Tinctura bryoniæ*, is a newly-introduced preparation, which is not recognized by other pharmacopœias. It should be remembered that the *Pharmacopœia* defines calendula to be the fresh flowering herb, and that two cultivated species of *Tagetes* are likewise popularly known as marigold (see page 357). The intention seems to be that calendula, freshly gathered, should be at once dried, powdered, and converted into tincture.

Action and Uses.—Considering the deobstruent virtues attributed to calendula, alcohol does not appear to be an appropriate vehicle for its administration. The tincture, however, is convenient for topical application.

TINCTURA CALUMBÆ, *U. S., Br.*—TINCTURE OF CALUMBA.

Tinctura colombo.—*Teinture de colombo*, *Fr.*; *Kolombotinktur*, *G.*

Preparation.—Calumba, in No. 20 powder, 10 parts (3 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 parts (30 oz. av.). Mix alcohol and water in the proportion of 3 parts (18 oz. av. or 21 fluidounces) of alcohol to 2 parts (12 oz. av. or 11½ fluidounces) of water, and, having moistened the powder with 10 parts (3 oz. av. or 3½ fluidounces) of the mixture, macerate for 24 hours; then pack it in a cylindrical percolator, and gradually pour menstruum upon it until 100 parts (30 oz. or about 32 fluidounces) of tincture are obtained.—*U. S.*

Columbo 2½ oz. av., proof spirit sufficient for 1 pint (Imperial).—*Br.* Columbo 1 part, alcohol (sp. grav. .912) 5 parts.—*F. Cod.*

The alcoholic strength of the menstruum has been very properly increased, and is now slightly above that of the French Codex. The tincture has a brown-yellow color, and is much less prone to unsightly precipitation than that of the former *Pharmacopœia*, which was made with diluted alcohol.

Medical Uses.—This tincture possesses all the virtues of calumba, and may be given for the same purposes as that medicine. It is chiefly employed as a stomachic tonic during convalescence from acute diseases and in *feeble states of digestion* from other causes. It may also be added to bitter infusions where a special stimulant action is desired. The *dose* is 1 or 2 fluidrachms (*Gm.* 4–8).

TINCTURA CANNABIS INDICÆ, *U. S., Br., P. G.*—TINCTURE OF INDIAN CANNABIS.

Tinctura cannabis, *U. S.* 1870.—*Tincture of hemp* (*Indian hemp*), *E.*; *Teinture de chanvre de l'Inde*, *Fr.*; *Indischhanftinktur*, *G.*

Preparation.—Indian Cannabis, in No. 40 powder, 20 parts (6 oz. av.); Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 20 parts (6 oz. av. or 7 fluidounces) of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it until 100 parts (30 oz. av. or about 35 fluidounces) of tincture are obtained.—*U. S.*

The tincture of the French Codex is apparently of the same strength, but is made with alcohol spec. grav. .912, which is too weak a menstruum. It is to be regretted that the present formula must be regarded as the reverse of an improvement. Good Indian cannabis yields about 12½ per cent. of alcoholic extract; the tincture will therefore contain about 2½ per cent. of extract, or about 150 grains in the pint. The *Pharmacopœia* of 1870 ordered 360 grains of extract to the pint. The British and German *Pharmacopœias* direct this tincture to be made from the extract, and both preparations are practically of the same strength, and double that of the *U. S. P.*

Extract of Indian hemp 1 oz. av., rectified spirit 1 pint.—*Br.*

Extract of Indian hemp 1 part, alcohol (sp. grav. .832) 19 parts.—*P. G.*

Medical Uses.—The tincture of Indian hemp may be employed for the same purposes as the extract of that plant, but is ineligible on account of the precipitation of its resin by water. The primary *dose* is about 20 minims (*Gm.* 1.30).

TINCTURA CANTHARIDIS, U. S., Br., F. Cod.—TINCTURE OF CANTHARIDES.

Tinctura cantharidum, P. G.—*Teinture de cantharides*, Fr.; *Spanischfliegentinktur*, G.

Preparation.—Cantharides, in No. 60 powder, 5 parts ($1\frac{1}{2}$ oz. av.); Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 3 parts of alcohol, and pack it firmly in a cylindrical percolator; then gradually pour alcohol upon it until 100 parts (30 oz. av. or about 35 fluidounces) of tincture are obtained.—*U. S.*

The proportions directed by other pharmacopœias are—Cantharides $\frac{1}{4}$ oz. av., proof spirit 1 pint (Imperial).—*Br.* Cantharides 1 part, alcohol 10 parts.—*F. Cod., P. G.*

The tincture has the burning taste and the peculiar odor of cantharides. Made with alcohol, it is of a greenish-yellow color; but diluted alcohol dissolves the dark extractive matter and yields a brown-yellow tincture. The tincture of the U. S. P. 1870 was made with diluted alcohol, and represented in the fluidounce 15 grains (the present one 18.7 grains) of cantharides.

Medical Uses.—This preparation is convenient for use in the comparatively rare cases in which cantharides are internally administered. It may be prescribed in doses of from 10 to 20 drops (Gm. 0.60–1.20) and upward until vesical irritation is produced. Tincture of cantharides should be administered largely diluted in a mucilaginous vehicle. The external uses of this preparation include numerous cases in which a more prolonged and sustained irritation, amounting sometimes to rubefaction, is required than can be obtained by more immediate irritants. Although sometimes applied in liniments to the whole surface of the body, it is manifestly less appropriate to such a purpose than stimulants which act more promptly and for a shorter time; its proper use is as a substitutive stimulant in local *torpor*, *congestions*, *inflammations*, and *pains*, in *neuralgia* of certain nerves, *alopecia*, *frost-bite*, *fistulous ulcers*, etc. The following liniment is used in alopecia: ℞. Cologne-water fʒj; Tincture of Cantharides fʒiss; Tinctures of Rosemary and Lavender, each 10 drops. The scalp should be gently rubbed every day with this lotion, applied on a sponge or piece of flannel.

TINCTURA CAPSICI, U. S., Br., P. G.—TINCTURE OF CAPSICUM.

Teinture de piment des jardins, Fr.; *Spanischpfeffertinktur*, G.

Preparation.—Capsicum, in No. 30 powder, 5 parts ($1\frac{1}{2}$ oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 parts (30 oz. av.). Mix alcohol and water in the proportion of 19 parts ($28\frac{1}{2}$ oz. av. or $33\frac{3}{8}$ fluidounces) of alcohol to 1 part ($1\frac{1}{2}$ oz. av. or $11\frac{1}{2}$ fluidrachms) of water, and, having moistened the powder with 3 parts of the mixture, pack it firmly in a cylindrical percolator; then gradually pour menstruum upon it until 100 parts (30 oz. av. or about 34 fluidounces) of tincture are obtained.—*U. S.*

Other pharmacopœias direct—Capsicum $\frac{3}{4}$ ounce (av.), rectified spirit sufficient for 1 pint (Imperial).—*Br.* Capsicum 1 part, alcohol 10 parts.—*P. G.*

The tincture has a light reddish-orange color and the fiery taste of capsicum. Made according to the U. S. P. 1870, diluted alcohol was used, and a fluidounce of it contained 15 grains (the present tincture 19 grains) of capsicum; the color of the latter is somewhat lighter.

Medical Uses.—This tincture can be used for most of the purposes for which capsicum has been recommended, and especially as an addition to gargles, rubefacient liniments, and mixtures intended to stimulate the stomach exhausted by alcoholic excesses. It may be prescribed in doses of 1 or 2 fluidrachms (Gm. 4–8), appropriately diluted.

TINCTURA CARDAMOMI, U. S.—TINCTURE OF CARDAMOM.

Teinture de cardamome, Fr.; *Kardamomentinktur*, G.

Preparation.—Cardamom, in No. 30 powder, 15 parts ($4\frac{1}{2}$ oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 15 parts ($4\frac{1}{2}$ oz. av. or $4\frac{3}{4}$ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—*U. S.*

It is of a brown-yellow color, and has the aromatic odor and spicy taste of cardamom.

Medical Uses.—The simple is much less used than the compound tincture of cardamom. It may, however, be prescribed as a carminative in the *dose* of 1 or 2 fluidrachms (Gm. 4–8).

TINCTURA CARDAMOMI COMPOSITA, U. S., Br.—COMPOUND TINCTURE OF CARDAMOM.

Teinture de cardamome composée, Fr. ; Zusammengesetzte Kardamomentinktur, G.

Preparation.—Cardamom 20 parts (1 oz. av.); Cinnamon 20 parts (1 oz. av.); Caraway 10 parts ($\frac{1}{2}$ oz. av.); Cochineal 5 parts ($\frac{1}{4}$ oz. av.); Glycerin 60 parts (3 oz. av.); Diluted Alcohol a sufficient quantity; to make 1000 parts (50 oz. av. or about 50 fluidounces). Mix the cardamom, cinnamon, caraway, and cochineal, and reduce them to a moderately coarse (No. 40) powder. Having moistened the powder with 25 parts ($1\frac{1}{4}$ fluidounces) of diluted alcohol, pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 940 parts (47 oz. av. or about $47\frac{1}{2}$ fluidounces) of tincture are obtained; then add the glycerin, and mix them.—*U. S.*

Cardamom-seeds, freed from the pericarps, and caraway-fruit, each $\frac{1}{4}$ ounce; raisins, freed from their seeds, 2 ounces; cinnamon-bark $\frac{1}{2}$ ounce (av.); cochineal 55 grains; proof spirit sufficient for 1 pint (Imperial).—*Br.*

Both tinctures have a red color, due to cochineal, and are of an agreeable aromatic odor and taste.

Off. Prep.—Decoct. aloes comp., Mist. ferri arom., Mist. sennæ comp., Tinct. chloroformi comp., *Br.*

Medical Uses.—This tincture, on account of its brilliant color and carminative properties, is, when mixed with sweetened hot water, a favorite remedy for flatulent *colic*. It is a customary addition to mixtures intended to relieve similar affections. The *dose* is 1 or 2 fluidrachms (Gm. 4–8).

TINCTURA CASCARILLÆ, Br.—TINCTURE OF CASCARILLA.

Teinture de cascarrille, Fr. ; Kaskarilltinktur, G.

Preparation.—Take of Cascarilla-Bark $2\frac{1}{2}$ oz. av.; proof spirit 1 pint (Imperial). Macerate and finish the tincture by the process described under TINCTURÆ.—*Br.* Cascarilla 1 part, alcohol (sp. grav. .863) 5 parts.—*F. Cod.*

The tincture has a reddish-brown color.

Medical Uses.—Although not generally used in this country, it is not unworthy of being employed in cases requiring a tonic and stimulant operation. It is especially useful in *dy-peptic* gastro-intestinal derangements due to atony, and is beneficially associated in these affections and others with compound tincture of cinchona. The *dose* is from $\frac{1}{2}$ to 2 fluidrachms (Gm. 2–8).

TINCTURA CASTOREI, F. Cod., P. G.—TINCTURE OF CASTOR.

Teinture de castoreum, Fr. ; Bibergeiltinktur, G.

Preparation.—Take of Castor, in coarse powder, 1 oz. av.; Rectified Spirit 1 pint. Macerate for seven days in a closed vessel, with occasional agitation; strain, press, filter, and add sufficient rectified spirit to make 1 pint (Imperial).—*Br.*, 1867.

Macerate 1 part of castor in 10 parts of alcohol (sp. grav. .863).—*F. Cod.* (sp. grav. .832, *P. G.*).

The tincture has a deep reddish-brown color, is rendered opalescent by water, and with a larger quantity of water becomes milky, of a dingy brownish-white color, deposits red-brown resinous matter, and on standing becomes nearly colorless and almost transparent; on the addition of excess of ammonia the resin remains undissolved (see page 400).

TINCTURA ÆTHEREA CASTOREI. Castor 1 part, ether (sp. gr. .724) 7 parts, alcohol 3 parts.—*F. Cod.*

Medical Uses.—Tincture of castor is seldom employed, but in the obligatory variation of medicines used in the treatment of *hysterical disorders* it may occasionally find its place, particularly in enemas. The latter method is peculiarly appropriate when an hysterical attack occurs about the *menstrual period*, with symptoms of utero-ovarian irritation and flatulent distension of the bowels. The ataxic state of *low fevers* may be treated in the same manner, but with less prospect of doing good than by the use of asafetida, valerian, opium, or simply alcohol. *Dose*, from $\frac{1}{2}$ to 2 fluidrachms (Gm. 2–8).

TINCTURA CATECHU COMPOSITA, U. S.—COMPOUND TINCTURE OF CATECHU.

Tinctura catechu, U. S. 1870, Br., P. G.—*Tinture de cachou*, Fr.; *Katechutinktur*, G.

Preparation.—Catechu, in No. 40 powder, 12 parts (3 oz. av.); Cinnamon, in No. 40 powder, 8 parts (2 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (25 oz. av.). Mix the powders, and, having moistened the mixture with 15 parts (3½ oz. av. or 3½ fluidounces) of diluted alcohol, macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (25 oz. av. or about 25 fluidounces) of tincture are obtained.—U. S.

The formulas of other pharmacopœias direct: Pale catechu 2½ oz. av., cinnamon-bark 1 ounce av., proof spirit sufficient for 1 pint (Imperial).—Br. Catechu 1 part, alcohol (sp. grav. .912 or .894) 5 parts.—F. *Cod.*, P. G.

The tincture has a dark red-brown color, a strongly astringent taste, and an acid reaction; it does not become milky on the addition of water, produces with ferric salts green-black precipitates, and when heated with potassium bichromate becomes brownish-red.

Medical Uses.—Compound tincture of catechu is used internally chiefly for the purpose of diminishing *diarrhœa*. When the latter affection is acute, the tincture is generally administered in chalk mixture; when chronic, it is often given with port wine. Externally, it is useful as a dressing for indolent *ulcers* of soft tissues, and particularly of the *nipples* and *anus*. Diluted with water, it may be injected into the *rectum* or *vagina* in chronic *fluxes* of those organs. The *dose* is from 30 minims to 2 fluidrachms (Gm. 2–8).

TINCTURA CHIRATÆ, U. S., Br.—TINCTURE OF CHIRATA.

Tincture of chiretta, E.; *Teinture de chirette*, Fr.; *Chirettatinktur*, G.

Preparation.—Chirata, in No. 40 powder, 10 parts (3 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 10 parts (3 oz. av. or 3½ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—U. S.

Chiretta, cut small and bruised, 2½ oz. av.; proof spirit 1 pint (Imperial). Prepare the tincture by the process described under TINCTURÆ.—Br.

Medical Uses.—The medicinal qualities of this preparation are closely analogous to those of *columbo*. It is but little used in this country. *Dose*, from 30 minims to 2 fluidrachms (Gm. 2–8).

TINCTURA CHLOROFORMI COMPOSITA, Br.—COMPOUND TINCTURE OF CHLOROFORM.

Preparation.—Take of Chloroform 2 fluidounces; Rectified Spirit 8 fluidounces; Compound Tincture of Cardamom 10 fluidounces. Mix.—Br.

TINCTURA CHLOROFORMI ET MORPHINÆ, Br. Dissolve morphine hydrochlorate 8 grains, and oil of peppermint 4 minims, in rectified spirit 1 fluidounce, and add chloroform 1 fluidounce and ether 2 fluidrachms. Mix liquid extract of liquorice and treacle each 1 fluidounce with syrup 3 fluidounces, add this to the above solution; then add diluted hydrocyanic acid ½ fluidounce, and sufficient syrup to make 8 fluidounces.—Br. (See also CHLORODYNE, p. 440.)

Medical Uses.—This preparation is convenient for administering chloroform as a liquid internally. The *dose* is from 20 to 40 minims (Gm. 1.30–2.60). It is chiefly used for allaying flatulent, biliary, and renal *colics*, but has also been employed in *delirium tremens* and in *mania-à-potu*. (For remarks on CHLORODYNE, see p. 446.)

TINCTURA CIMICIFUGÆ, U. S., Br.—TINCTURE OF CIMICIFUGA.

Tincture of black snakeroot, E.; *Teinture d'actée à grappes*, Fr.; *Cimicifugatinktur*, G.

Preparation.—Cimicifuga, in No. 60 powder, 20 parts (6 oz. av.); Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 15 parts (4½ oz. av. or 5 fl. oz.) of alcohol, macerate for 24 hours, pack firmly in a cylindrical percolator, and with alcohol obtain 100 parts (30 oz. av. or about 34 fl. oz.) of tincture.—U. S.

Cimicifuga in No. 40 powder 2½ oz.; proof spirit sufficient for 20 fl. oz.—Br.

Medical Uses.—The tincture of cimicifuga seems to be an unnecessary medicine,

since the fluid extract contains all the virtues of the drug in a smaller quantity of alcohol. *Dose*, from 1 to 2 or 3 fluidrachms (Gm. 4-12).

TINCTURA CINCHONÆ, U. S., Br.—TINCTURE OF CINCHONA.

Tinctura cinchona flavæ, F. Cod.; *Tinctura chinæ*, P. G.—*Tincture of yellow cinchona*, E.; *Teinture de quinquina jaune*, Fr.; *Chinatinktur*, G.

Preparation.—Yellow Cinchona, in No. 60 powder, 20 parts (6 oz. av.); Glycerin 10 parts (3 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 parts (30 oz. av.). Mix the glycerin with 65 parts (19½ oz. av. or 22½ fluidounces) of alcohol and 25 parts (7½ oz. av. or 7½ fluidounces) of water, and, having moistened the powder with 20 parts (6 oz. av.) of the mixture, macerate for 24 hours; then pack it firmly in a cylindrical glass percolator, and gradually pour on the remainder of the mixture. When the liquid has disappeared from the surface gradually pour on more of the mixture of alcohol and water, using the same proportions as before, and continue the percolation until 100 parts (30 oz. av. or about 32 fluidounces) of tincture are obtained.—U. S.

Other pharmacopœias employ—Red cinchona 4 ounces av., proof spirit sufficient for 1 pint (Imperial).—Br. Yellow cinchona 1 part, alcohol (sp. grav. .912) 5 parts—F. Cod. Cinchona containing 3½ per cent. of alkaloids 1 part, alcohol (sp. grav. 0.894) 5 parts.—P. G.

The tincture has a red-brown color, and, if not sufficiently strong in alcohol, deposits a sediment of cinchonic red containing kinates of the alkaloids. Mr. A. B. Taylor (1865) found a menstruum composed of 2 measures of alcohol and 1 measure each of water and glycerin capable of preventing this precipitation for several months. The present U. S. P. uses alcohol and water nearly in the same proportion as before, and adds a small quantity of glycerin, equal to about one-fifteenth of the measure of the menstruum.

Medical Uses.—Tincture of cinchona is seldom given alone, but is generally used as an addition to tonic mixtures, infusions, etc., and especially for modifying the taste of solutions of quinia. But for these and all other purposes the compound tincture is preferable. *Dose*, 1 or 2 fluidrachms (Gm. 4-8).

TINCTURA CINCHONÆ COMPOSITA, U. S., Br.—COMPOUND TINCTURE OF CINCHONA.

Tinctura chinæ composita, P. G.; *Huxham's tincture of bark*, E.; *Teinture de quinquina composée*, *Elixir fébrifuge d'Huxam*, Fr.; *Zusammengesetzte Chinatinktur*, G.

Preparation.—Red Cinchona 10 parts (2½ oz. av.); Bitter Orange-Peel 8 parts (2 oz. av.); Serpentaria 2 parts (½ oz. av.); Glycerin 10 parts (2½ oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 parts (25 oz. av.). Mix the glycerin with 80 parts (20 oz. av. or 23½ fluidounces) of alcohol and 10 parts (2½ oz. av. or 2½ fluidounces) of water. Having mixed the cinchona, orange-peel, and serpentaria, reduce them to a fine (No. 60) powder. Moisten the powder with 20 parts (5 oz. av.) of the menstruum, and macerate for 24 hours; then pack it firmly in a cylindrical glass percolator, and gradually pour on the remainder of the menstruum. When the liquid has disappeared from the surface, gradually pour upon it enough of a mixture of alcohol and water, using the same proportions as before, and continue the percolation until 100 parts (25 oz. av. or about 27 fluidounces) of tincture are obtained.—U. S.

Red cinchona 2 oz. av.; bitter orange-peel 1 oz. av.; serpentary-root ½ oz. av.; saffron 55 grains; cochineal 28 grains; proof spirit sufficient to obtain 1 pint (Imperial).—Br.

The tincture of the German Pharmacopœia is also known as *Elixir roborans Whyttii*, and is composed of cinchona 6 parts, orange-peel and gentian-root, each 2 parts, Chinese cinnamon 1 part, alcohol (spec. grav. .894) 50 parts.

The first formula directs a menstruum containing nearly one-fourth more alcohol than is ordered for the simple tincture of cinchona; the strength of the latter appears to be ample also for the compound tincture. The preparation has a deep red-brown color, an aromatic odor, and a bitter and astringent taste.

Medical Uses.—The one disease—or morbid condition, rather—in which this preparation of cinchona is superior to all others is the *typhoid state*, whatever may be the original affection during which it is developed. In doing good the cinchona is aided by the serpentaria and alcohol of the compound, if not, as was once believed, by the saffron

also (*Br. P.*). It should be given in small and repeated doses of from 1 to 2 fluidrachms (*Gm.* 4–8), with 3 or 4 parts of water.

TINCTURA CINNAMOMI, *U. S., Br., F. Cod., P. G.*—TINCTURE OF CINNAMON.

Teinture de cannelle, *Fr.*; *Zimmttinktur*, *G.*

Preparation.—Cinnamon, in No. 40 powder, 10 parts (3 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 parts (30 oz. av.). Mix alcohol and water in the proportion of 3 parts (18 oz. av. or 21 fluidounces) of alcohol to 2 parts (12 oz. av. or 11½ fluidounces) of water, and, having moistened the powder with 5 parts (1½ oz. av. or 1½ fluidounces) of menstruum, pack it in a conical percolator, and gradually pour menstruum upon it until 100 parts (30 oz. av. or about 32 fluidounces) of tincture are obtained.—*U. S.*

Ceylon cinnamon 2½ oz. av., proof spirit sufficient for 1 pint (Imperial).—*Br.* Ceylon cinnamon 1 part, alcohol (sp. grav. .863) 5 parts.—*F. Cod.* Chinese cinnamon 1 part, alcohol (sp. grav. 0.894) 5 parts.—*P. G.*

The tincture has a red-brown color and a sweetish, warmly aromatic, and somewhat astringent taste. It sometimes gelatinizes when the menstruum becomes too weak in alcohol.

Medical Uses.—The agreeable taste and slight astringency of this preparation render it a suitable addition to mixtures intended to check recent diarrhœa. It may be added to lime-water to control nausea and vomiting. *Dose*, ½ to 2 fluidrachms (*Gm.* 2–8).

TINCTURA COCCI, *Br.*—TINCTURE OF COCHINEAL.

Teinture de cochenille, *Fr.*; *Cochenilletinktur*, *G.*

Preparation.—Take of Cochineal, in powder, 2½ oz. av.; Proof Spirit 1 pint (Imperial). Macerate for 7 days in a closed vessel, with occasional agitation; strain, press, filter, and add sufficient proof spirit to make 1 pint.—*Br.* Cochineal 1 part, alcohol (spec. grav. .863) 10 parts.—*F. Cod.*

This tincture has a deep-red color, which is affected by reagents, as described on page 479.

Medical Uses.—It is used exclusively for coloring tinctures, ointments, and mixtures.

TINCTURA COLCHICI, *U. S., P. G.*—TINCTURE OF COLCHICUM.

Tinctura colchici seminum, *Br.*—*Tincture of colchicum-seeds*, *E.*; *Teinture de colchique*, *Fr.*; *Zeitlosentinktur*, *G.*

Preparation.—Colchicum-Seed, in No. 30 powder, 15 parts (4½ oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 15 parts (4½ oz. av. or 4½ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it moderately in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—*U. S.*

Colchicum-seed 2½ oz. av., proof spirit sufficient for 1 pint (Imperial).—*Br.* Colchicum-seed 1 part, alcohol (sp. gr. 0.912) 5 parts.—*F. Cod.* Colchicum-seed 1 part, alcohol (sp. grav. .894) 10 parts.—*P. G.*

That unbroken colchicum-seeds may be completely deprived of colchicine by digestion has been mentioned on page 483; but all the pharmacopœias direct the seeds to be bruised or powdered. The tincture is of a brownish-yellow color, has a bitter taste, and becomes opalescent with water.

Medical Uses.—This tincture possesses the proper virtues of colchicum, and may be used as well as the wine. The difference of alcoholic strength between it and the wine can make no perceptible difference in the effects of such doses as are employed in practice. The *dose* is from 10 to 30 minims (*Gm.* 0.60–2).

TINCTURA CONII, *U. S., Br.*—TINCTURE OF CONIUM.*Teinture de ciguë, Fr.; Schierlingstinktur, G.*

Preparation.—Conium, in No. 30 powder, 150 parts (4½ oz. av.); Diluted Hydrochloric Acid 4 parts (52 grains or minims); Diluted Alcohol a sufficient quantity; to make 1000 parts (30 oz. av.). Moisten the powder with 45 parts (1¾ oz. av. or 9½ fluidrachms) of diluted alcohol, previously mixed with the diluted hydrochloric acid, and macerate for 24 hours; then pack it moderately in a conical glass percolator, and gradually pour diluted alcohol upon it until 1000 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—*U. S.*

This tincture is now very properly prepared from the full-grown but still green fruit, which, in our opinion, should be bruised and exhausted by maceration, so as to prevent the volatilization of a portion of the alkaloid. For reducing conium-fruit to powder it should be dried at as low a temperature as possible. The acid is added to the menstruum with the view of fixing the alkaloid.

The British Pharmacopœia likewise directs the fruit, in the nearly ripe state, 2½ oz. av. being used with sufficient proof spirit to obtain 1 Imperial pint. The tincture of the French Codex is made from the leaves 1 part and alcohol (sp. grav. .912) 5 parts. It has the peculiar nauseous odor and taste of the drug.

Medical Uses.—Tincture of conium cannot be regarded as an eligible preparation, inasmuch as the quantity of it capable of producing definite effects contains sufficient alcohol to counteract the sedative action of the conium. It is supplanted by the juice of conium. *Dose*, from 20 to 60 minims (Gm. 1.30–4).

TINCTURA CROCI, *U. S., Br., P. G.*—TINCTURE OF SAFFRON.*Teinture de safran, Fr.; Safrantinktur, G.*

Preparation.—Saffron 10 parts (1 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (10 oz. av.). Moisten the saffron with 10 parts (1 oz. av. or 8½ fluidrachms) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (10 oz. av. or about 10½ fluidounces) of tincture are obtained.—*U. S.*

Saffron 1 oz. av.; proof spirit sufficient for 1 pint (Imperial).—*Br.*

Saffron 1 part. Macerate with 10 parts of alcohol (sp. grav. .863, *F. Cod.*) (sp. gr. .894, *P. G.*) for 10 days; express, and filter.—*F. Cod., P. G.*

The tincture is of a rich orange-yellow color, and has the odor and taste of saffron.

Medical Uses.—Tincture of saffron is rarely given alone internally. It is chiefly employed to impart a pleasing color to mixtures. *Dose*, 1 or 2 fluidrachms (Gm. 4–8).

TINCTURA CUBEÆ, *U. S., Br.*—TINCTURE OF CUBEÆ.*Teinture de cubèbe, Fr.; Kubentinktur, G.*

Preparation.—Cubeæ, in No. 30 powder, 10 parts (3 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 10 parts (3 oz. av. or 3½ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—*U. S.*

Powdered cubebs 2½ oz. av., proof spirit sufficient to obtain 1 pint (Imperial).—*Br.*
Powdered cubebs 1 part, alcohol (sp. gr. .863) 5 parts.—*F. Cod.*

The tincture has a brownish color. It is too weak in alcohol for dissolving much of the volatile oil or resin contained in good cubebs; both these constituents are present in the French tincture, which becomes milky with water.

Medical Uses.—Tincture of cubeb is chiefly of use in *gleet*, but sometimes also as a carminative. The *dose* is from ½ to 2 fluidrachms (Gm. 2–8).

TINCTURA DIGITALIS, *U. S., Br.*—TINCTURE OF DIGITALIS.*Teinture de digitale, Fr.; Fingerhuttinktur, G.*

Preparation.—Digitalis, recently dried and in No. 60 powder, 15 parts (4½ oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 15 parts (4½ oz. av. or 4½ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol

upon it until 100 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—*U. S.*

Digitalis 2½ oz. av., proof spirit sufficient for 1 pint (Imperial).—*Br.* Digitalis 1 part, alcohol (sp. grav. .912) 5 parts.—*F. Cod.* Dried digitalis-leaves 1 part, alcohol (sp. grav. .894) 10 parts.—*P. G.*

Digitalis not growing wild in North America, and the cultivated plant being of doubtful medicinal value, it will be difficult to comply with the directions to use recently-dried leaves only. The tests given on p. 545 are valuable for determining the quality of digitalis; namely, the infusion made with 30 parts of water should become distinctly turbid with a solution of tannin, and the infusion with 10 parts of water should not yield a precipitate with ferric chloride. The tincture has a brown-green color, the peculiar odor of the leaves, and a bitter taste.

TINCTURA DIGITALIS ÆTHEREA. Bruised digitalis 1 part, ether (sp. grav. .758) 5 parts.—*F. Cod.* It is of a dark-green color.

Medical Uses.—The special virtues of digitalis are possessed by this preparation, which is more used than any other to obtain the action of the drug upon the heart. Its convenience, rather than its superiority to the infusion, has probably led to this custom. Friction of the abdomen and of other parts of the body with tincture of digitalis has sometimes been followed by diuresis in dropsy. *Dose*, from 10 to 20 minims (Gm. 0.60–1.20) three times a day. Great care should be taken in obtaining a new parcel of the medicine to learn whether it be of the same strength as that previously used.

TINCTURA ERGOTÆ, *Br.*—TINCTURE OF ERGOT.

Tinctura secalis cornuti.—*Teinture de seigle ergoté*, Fr.; *Mutterkorntinktur*, G.

Preparation.—Take of Ergot, finely comminuted, 5 oz. av.; Proof Spirit 1 pint (Imperial). Prepare the tincture by the process described under TINCTURÆ.—*Br.*

The tincture has a red-brown color and the odor and taste of ergot.

Medical Uses.—The stimulant action of the alcohol in this preparation probably renders it less eligible than the wine or the fluid extract of ergot. The *dose* is from 10 minims to a fluidrachm (Gm. 0.60–4).

TINCTURA FERRI ACETATIS, *U. S.*, *Br.*—TINCTURE OF ACETATE OF IRON.

Tinctura ferri acetici ætherea, *P. G.*—*Tincture of ferric acetate*, E.; *Teinture d'acétate de fer*, Fr.; *Eisenacetattinktur*, G.

Preparation.—Solution of Acetate of Iron 50 parts (5 oz. av. or 4½ fluidounces); Alcohol 30 parts (3 oz. av. or 3½ fluidounces); Acetic Ether 20 parts (2 oz. av. or about 17½ fluidrachms); to make 100 parts (10 oz. av.). Mix the alcohol and acetic ether, and gradually add the solution of acetate of iron, taking care that the mixture remains cool. Keep the tincture in glass-stoppered bottles in a cool and dark place.—*U. S.*

Solution of ferric acetate 80 parts, alcohol 12 parts, acetic ether 8 parts.—*P. G.*

Take of strong solution of acetate of iron 5 fluidounces; acetic acid 1 fluidounce; rectified spirit 5 fluidounces; distilled water 9 fluidounces. Mix, and then add sufficient distilled water to make 20 fluidounces. Preserve in a stoppered bottle.—*Br.*

On mixing solutions of ferric sulphate and potassium acetate the mixture assumes a dark blood-red color from the formation of ferric acetate; $\text{Fe}_2\text{SO}_4 + 6\text{KC}_2\text{H}_3\text{O}_2$ yields $\text{Fe}_2\text{C}_2\text{H}_3\text{O}_2 + 3\text{K}_2\text{SO}_4$. The sulphate of potassium which is produced at the same time, being insoluble in alcohol, is precipitated, and the filtrate will be an alcoholic solution of normal ferric acetate. This process of double decomposition has been abandoned in the present British Pharmacopœia for a tincture which contains an excess of acetic acid, while that of the U. S. P. contains normal ferric acetate, and that of the P. G. a more basic salt (see p. 899); the last two authorities order also the addition of acetic ether. The solution of ferric acetate, *Br.* (see p. 899), is of the same strength as the tincture, but contains less free acetic acid.

Properties.—This tincture is “a clear, dark reddish-brown liquid, transparent in thin layers, having the odor of acetic ether, an acidulous and astringent taste, and a slightly acid reaction. Sp. gr. about 0.950 (1.044–1.046, *P. G.*). It is miscible in all proportions with water, without becoming turbid.”—*U. S.*, *P. G.* For reasons stated on page 899 the tincture must be kept in the dark and in a cool place.

A weak tincture or solution of ferric acetate is largely used as a *wood-stain*. Woods containing tannin are thereby colored black, resembling ebony. To produce the same imitation with wood which is free from tannin, this is first soaked in a solution of extract of logwood before it is treated with ferric acetate.

Tests.—The diluted tinctures, after being precipitated by an excess of ammonia, yield a filtrate which should not be precipitated by sulphuretted hydrogen (zinc, copper), barium chloride (sulphate), or, after having been acidulated with nitric acid, by nitrate of silver (chloride); and on being evaporated and ignited should not leave any fixed residue (alkalies, earths).

“20 Gm. of the tincture carefully evaporated and, after addition of a few drops of nitric acid, ignited, should yield a residue weighing 1.12 Gm.”—*U. S.* 10 Gm. of the solution are required to leave 1.13 Gm. of ferric oxide. (See also tests on p. 900.)

Medical Uses.—This preparation is reputed by English authorities to be not only an excellent chalybeate for general purposes, but also one of the best of the *styptic* ferruginous preparations for internal administration. It should be given largely diluted with water and taken in small and repeated doses. The *dose* is from 5 to 30 minims (Gm. 0.20–2). The acetic-etheral tincture is convenient in hysterical anæmic cases, but only as an occasional substitute for the more actively reconstituent preparations of iron.

TINCTURA FERRI CHLORIDI, *U. S.*—TINCTURE OF CHLORIDE OF IRON.

Tinctura ferri perchloridi, Br.; *Tinctura ferri sesquichloridi*.—*Tincture of perchloride of iron*, *Tincture of ferric chloride*, E.; *Teinture de perchlorure de fer*, Fr.; *Eisenchloridtinktur*, G.

Preparation.—Solution of Chloride of Iron 35 parts (8½ oz. av. or 6 fluidounces); Alcohol 65 parts (16¼ oz. av. or 19 fluidounces); to make 100 parts (25 oz. av. or nearly 25 fluidounces). Mix the solution with the alcohol, and let it stand in a closely-covered vessel at least three months; then transfer it to glass-stoppered bottles.—*U. S.*

Mix strong solution of perchloride of iron 5 fluidounces with rectified spirit 5 fluidounces and distilled water 10 fluidounces.—*Br.*

The two tinctures are practically alike, except that the first contains free hydrochloric acid, and when it is kept on hand for some time, as now directed by the Pharmacopœia, previous to dispensing it, acquires an ethereal odor from the formation of various compounds, resulting from the action upon the alcohol of the free acid, and probably also of the ferric chloride, the latter being reduced to ferrous chloride more particularly on exposing the tincture to the light. Notwithstanding this gradual reduction is well known, the *U. S. P.* requires the tincture, on the addition of freshly-prepared test solution of potassium ferricyanide, to acquire merely a greenish-brown color without a trace of blue; which is simply an impossibility, the tincture being even not directed to be kept in the dark, which would at least lessen, though not entirely prevent, the reducing action. The present Br. P. has reduced the alcohol to ⅓ the former strength.

Tincture of ferric chloride is perfectly transparent, and has a brown-yellow or bright brownish color, an agreeable ethereal odor, a strongly astringent, ferruginous taste, and an acid reaction. Its specific gravity is .988 (*U. S.*). The tincture behaves to alkalies, potassium ferrocyanide, and silver nitrate like the solution (see page 901). Dr. Robert Battey and Mr. J. C. Wharton (1870) occasionally observed the tincture to deposit white crystals of sulphate of calcium, which were probably derived from impurity in the acid.

Tests.—Impurities like nitric acid, sulphate of copper, zinc, alkalies, and ferric oxychloride are detected in the same manner as stated for the salt and the solution (see pp. 676 and 901). In testing for oxychloride the Pharmacopœia directs 8 parts of the tincture to be diluted with 100 parts of distilled water before boiling. “10 Gm. of the tincture, when completely precipitated by excess of water of ammonia, yield a precipitate which, when washed, dried, and ignited, should weigh 0.652 Gm.”—*U. S.*

Off. Prep.—Mistura ferri et ammonii acetatis, *U. S.*

TINCTURA FERRI CHLORATI ÆTHEREA, *P. G.*, s. Tinctura tonico-nervina Bestuscheffii, s. Liquor anodynus martiatus, s. Spiritus ferri chlorati æthereus. 1 part of solution of ferric chloride spec. grav. 1.282 (containing 19.9 per cent. Fe_2Cl_6) is mixed with alcohol 7 parts and ether 2 parts, the mixture exposed to the sunlight until colorless, and afterward kept in partially filled bottles in a shady place until it has acquired a yellow color. During the bleaching process the ferric is reduced to ferrous chloride, chloride of ethyl

and a little aldehyd being generated through the influence of the nascent chlorine. On exposure to the air the salt is partly oxidized to ferric oxychloride. This is known as *Bestuscheff's tincture*. It has a warm and ferruginous taste, is precipitated black by ammonia, white by silver nitrate, and blue by both ferrocyanide and ferricyanide of potassium, and contains 1 per cent. of iron. 10 Cem. of this tincture, after being agitated with an equal volume of the solution of potassium acetate, should separate on standing 3 Cem. of ethereal liquid.

TASTELESS TINCTURE OF IRON, introduced by M. Creuse (1873), has the ferruginous taste modified by an alkali citrate, the compound formed being analogous in color and taste to the pharmacopœial phosphate and pyrophosphate of iron (see pp. 691 and 693). For 1 fluidounce of the tincture about 130 grains of citric acid neutralized by an alkali, or about 200 grains of potassium citrate, are required, and one-half the alcohol ordered by the Pharmacopœia should be replaced by water.

Physiological Action.—Tincture of chloride of iron is, of all ferruginous compounds except the solutions of the chloride and of the persulphate, the one that exerts the most powerful local action as a styptic, and indeed as a caustic, upon delicate tissues. Even when largely diluted it constricts the mouth and fauces. A diuretic action is attributed to it, which is probably due to the ether which it contains. It is very apt to attack the teeth unless properly diluted and taken through a tube. One or two cases are reported of strangury caused by its external application.

Medical Uses.—Like the solution of chloride of iron, this preparation may be used as a local styptic, but it is less efficient than the former. It is better suited for internal administration in all cases of passive *hemorrhage*, and especially in that from the uterus. It is eminently serviceable when hemorrhage depends upon imperfect coagulability of the blood, associated with a lax condition of the solids and general debility. For these reasons, doubtless, it is very efficient in *purpura hemorrhagica*. It is probably the best preparation that can be employed in chronic *albuminuria*, although the utility of other ferruginous preparations in the same affection proves that they do not act by their astringency as much as by their reconstituent power in the blood. Indeed, the form in which the tincture is ordinarily given in renal disorders, "Basham's mixture," no longer holds iron as a chloride, but as an acetate. Possibly, the free acids of this preparation act as diuretics. The formula for this solution is as follows: *℞. Tr. ferri chloridi f ʒss; Acid. acetic. dil. f ʒj; Liq. ammoniæ acetic. f ʒivss; Tr. aurant. cort. f ʒss; Glycerinæ f ʒss.*—*M. S.* A tablespoonful, largely diluted, two or three times a day. The tincture of the chloride is the best form in which iron can be given in *diabetes*.

In various chronic mucous fluxes, including *leucorrhœa*, *bleorrhœa*, *bronchorrhœa*, *diarrhœa*, and also in passive *sweats*, this preparation is often of essential service, both by its constricting action and its reconstituent operation. It is scarcely less efficient in *vesical catarrh*, especially when it is associated with paralysis of the bladder. Doubtless the double action just indicated renders it an efficient remedy for *seminal losses* due to an excessive or unnatural stimulation of the genital organs. To its astringency must probably be ascribed its remarkable efficacy in *idiopathic erysipelas* and its alleged utility in other forms of the same affection. In regard to the first-named disease, the virtues of the medicine are incontestable whenever it is administered in sufficient doses—*i. e.* of 20 to 30 drops (Gm. 1.30–2) every two hours, both night and day. In many cases of traumatic erysipelas its utility is equally well established. Applied topically and undiluted, it is said to prevent the spreading of the eruption (*Hopadze. Med. Record*, xix. 364), but this statement may not apply to the idiopathic affection. In *puerperal fever*, an affection which stands in the closest relationship to erysipelas, the power of this medicine has been unequivocally demonstrated (*Bell, Edinburgh Med. Jour.*, xxvi. 50, 74). In *diphtheria* this tincture is one of the most efficient topical applications to the parts on which the exudation is seated, and its internal administration in appropriate doses, such as from 5 to 15 drops (Gm. 0.30–1) every half hour or hour, has produced better results than any other medicine. When thus administered the special topical use of the medicine may be dispensed with (*Boston Med. and Surg. Jour.*, July, 1881, p. 58). As an application to *chilblains* it is sometimes used. It has also been employed, in large and repeated doses, in acute articular *rheumatism*, but, while the results show that it is tolerated in most instances, and appears to be beneficial in a small proportion of mild cases, yet the proportion of cardiac complications occurring during its administration seems to have been unusually large.

This tincture may be applied in the same manner as the solution of chloride of iron for arresting *hemorrhage*, whether external or internal. It may be inhaled as an atomized

solution in cases of pulmonary hæmorrhage. For the latter purpose a solution of 1 part of the tincture to 10 parts of water may be used.

The dose of this medicine is from 10 to 30 drops (Gm. 0.60–2), largely diluted with water.

TINCTURA GALLÆ, U. S., Br.—TINCTURE OF NUTGALL.

Tinctura gallarum, P. G.—*Tincture of galls*, E.; *Teinture de noix de galle*, Fr.; *Galläpfeltinktur*, G.

Preparation.—Nutmall, in No. 40 powder, 20 parts (6 oz. av.); Glycerin 10 parts (3 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Mix the glycerin with 90 parts (27 oz. av. or 28 fluidounces) of diluted alcohol, and, having moistened the powder with 10 parts of the mixture, pack it in a conical glass percolator; then gradually pour upon it, first, the remainder of the mixture, and afterward diluted alcohol, until 100 parts (30 oz. av. or about 29 fluidounces) of tincture are obtained.

—U. S.

Nutmall 2½ oz. av., proof spirit sufficient for 1 pint (Imperial).—Br. Macerate nutgall 1 part with 5 parts of alcohol spec. grav. .912 (*F. Cod.*), (sp. grav. .894, *P. G.*).

Nutmall yields over 60 per cent., or 20 parts yield at least 12 parts, of extract; the menstruum of the first formula weighing 100 parts, about one-eighth of it, containing ¾ oz. of glycerin, must remain in the powder. The addition of glycerin is intended to retard the formation of gallic acid, which is deposited if the tincture be long kept. The tincture has a yellowish-brown color, a strongly astrigent taste, and an acid reaction, and yields blue-black precipitates with ferric salts.

Medical Uses.—Tincture of nutgall is seldom given internally, but is sometimes used, diluted with water, as a lotion in relaxed conditions of the *mouth* and *fauces*, of the *rectum*, and of the *vagina*. Dose, from 30 minims to 2 fluidrachms (Gm. 2–8).

TINCTURA GELSEMI, U. S., Br.—TINCTURE OF GELSEMIUM.

Teinture de gelsemium, Fr.; *Gelsemiumtinktur*, G.

Preparation.—Gelsemium, in No. 60 powder, 15 parts (4½ oz. av.); Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 10 parts (3 oz. av. or 3½ fluidounces) of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it until 100 parts (30 oz. av. or about 35 fluidounces) of tincture are obtained.—U. S.

The tincture is of a brown-yellow color, becomes milky with water, and has the aromatic odor and bitter taste of the drug. A somewhat weaker alcohol would be equally well adapted, but alcohol spec. grav. .912, which is ordered by the French Codex for preparing *extract of gelsemium*, appears to be too aqueous for conveniently exhausting all the desirable principles. The Br. P. orders gelsemium 2½ ounces, proof spirit 20 fluidounces.

Medical Uses.—This preparation represents all the virtues and all the dangers of gelsemium. It may be prescribed in doses of 10 minims (Gm. 0.60), and gradually increased.

TINCTURA GENTIANÆ COMPOSITA, U. S., Br.—COMPOUND TINCTURE OF GENTIAN.

Preparation.—Gentian 8 parts (4 oz. av.); Bitter Orange-Peel 4 parts (2 oz. av.); Cardamom 2 parts (1 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (50 oz. av.). Mix the gentian, orange-peel, and cardamom, and reduce the mixture to a moderately coarse (No. 40) powder. Moisten the powder with 10 parts (5 oz. av. or 5½ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (50 oz. av. or about 51 fluidounces) of tincture are obtained.—U. S.

The British Pharmacopœia prepares 1 pint (Imperial) of tincture from gentian 1½ ounces, bitter orange-peel ¾ ounce, and ¼ ounce (av.) of cardamom-seeds deprived of the pericarps, using sufficient proof spirit.

The principal change in the first formula is the direction to powder the drugs together to prevent the loss of the volatile oil remaining in the dried aromatics. The tincture has a brown-yellow color, an agreeable aromatic odor, and a bitter taste. It acquires with ferric salts a dark black-brown color.

Allied Tinctures.—TINCTURA GENTIANÆ ALKALINA.—Teinture de gentiane alcaline (stomach-ique), Elixir amer de Peyrilhe, *F. Cod.*—Gentian 10 parts, crystallized sodium carbonate 3 parts, alcohol (sp. grav. .912) 300 parts.

TINCTURA GENTIANÆ.—Tincture of gentian, *E.*; Teinture de gentiane, *Fr.*; Enziantinktur, *G.*—Macerate gentian 1 part in 5 parts of alcohol spec. grav. .912 (*F. Cod.*), (sp. gr. .894, *P. G.*).

Medical Uses.—This tincture is a very agreeable bitter and an efficient stomachic in cases of *feeble digestion*. It is especially adapted to improve the tone of the stomach exhausted by the abuse of alcoholic drinks. The *dose* is 1 or 2 fluidrachms (*Gm.* 4–8).

TINCTURA GUAIACI, *U. S.*—TINCTURE OF GUAIAAC.

Teinture de résine de gayac, *Fr.*; *Guajak tinktur*, *G.*

Preparation.—Guaiac, in coarse powder, 20 parts (6 oz. av.); Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Mix the powder with 80 parts (24 oz. av. or 28½ fluidounces) of alcohol, and macerate for 7 days in a closed vessel; then filter through paper, adding, through the filter, enough alcohol to make the tincture weigh 100 parts (30 oz. av. or about 32 fluidounces).—*U. S.*

Since guaiac resin dissolves completely in alcohol with the exception of the impurities, the tincture is conveniently made by maceration. The formula directs the original weight to be made up, irrespective of the amount of insoluble impurities, by washing the filter with alcohol. The tincture has been dismissed from the German Pharmacopœia; that of the French Codex (1 part resin to 5 parts alcohol sp. gr. .863) is weaker. The tincture has a dark brownish-red color, is precipitated by water, and is colored green or blue by ferric chloride and other agents.

Allied Tincture.—TINCTURA GUAIACI LIGNI.—Tincture of guaiacum-wood, *E.*; Teinture de gayac, *Fr.*—Macerate for 10 days guaiacum-wood 10 parts in alcohol (spec. grav. .912) 50 parts; express and filter.—*Fr. Cod.*

Medical Uses.—The tincture may be used in most of the cases to which other preparations of guaiacum are adapted, but especially in chronic fibrous *rheumatism* and in scanty or painful *menstruation*. It has been especially recommended in *tonsillitis*. The ammoniated tincture is in general to be preferred, and may be used as a *gargle* in the proportion of a fluidrachm to 2 fluidounces of water. Both tinctures, being decomposed by water, should be administered internally in mucilage or syrup. *Dose*, 1 or 2 fluidrachms (*Gm.* 4–8) several times a day.

TINCTURA GUAIACI AMMONIATA, *U. S., Br.*—AMMONIATED TINCTURE OF GUAIAAC.

Teinture de gayac ammoniacale, *Fr.*; *Ammoniakalische Guajak tinktur*, *G.*

Preparation.—Guaiac, in coarse powder, 20 parts (4 oz. av.); Aromatic Spirit of Ammonia a sufficient quantity; to make 100 parts (20 oz. av.). Mix the powder with 80 parts (16 oz. av. or 17½ fluidounces) of aromatic spirit of ammonia, and macerate for 7 days in a closed vessel; then filter through paper, adding, through the filter, aromatic spirit of ammonia until 100 parts (20 oz. av. or about 20 fluidounces) of tincture are obtained.—*U. S.*

Guaiacum resin in powder 4 oz. av., aromatic spirit of ammonia sufficient for 1 pint (Imperial).—*Br.*

The two formulas yield practically identical tinctures, which resemble tincture of guaiac in appearance, but have an ammoniacal odor and taste.

Allied Tincture.—DEWEES'S TINCTURE OF GUAIAACUM. Digest for a few days powdered guaiacum resin 4 ounces, carbonate of sodium or potassium 90 grains, powdered pimento 1 ounce, in diluted alcohol 1 pint. Add spirit of ammonia, if required, in the proportion of 1 or 2 drachms to each 4 fluidounces of the tincture.

Medical Uses.—The uses of this preparation are the same as those of the simple tincture. It may be applied locally in *tonsillitis* by means of a brush. The ammonia it contains may possibly promote the curative effects of the resin. At all events, the ammoniated tincture is generally preferred. *Dose*, 1 or 2 fluidrachms (*Gm.* 4–8).

Deweese claimed that in idiopathic *amenorrhœa* of long standing he had for more than forty years almost daily used the preparation which bears his name, without its having failed in any case proper for its use. He prescribed a teaspoonful of it three times a day in a wine-glassful of milk or white wine.

TINCTURA HUMULI, U. S.—TINCTURE OF HOPS.*Tinctura lupuli, Br.; Teinture de houblon, Fr.; Hopfentinktur, G.*

Preparation.—Hops, well dried and in No. 20 powder, 20 parts (6 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 40 parts (12 oz. av. or 12½ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. or about 31 fluidounces) of tincture are obtained.—*U. S.*

The British tincture of hop is about one-third weaker and is made from 2½ ounces av. of hop, with sufficient proof spirit to obtain 1 pint (Imperial).

Hops should not be dried by artificial heat; when air-dry, they may be conveniently reduced to powder by grinding them together with some clean sand in an ordinary drug-mill; when unground, they are unsuited for percolation, and so bulky that in preparing the tincture by maceration most of the liquid is absorbed, necessitating the frequent agitation of the mixture and afterward its forcible expression. The tincture is of a yellowish-brown color, and has the odor and bitter taste of hop, though in less degree than the tincture of lupulin, which has been dismissed from the present Pharmacopœia (see p. 939).

Medical Uses.—The proportion of hops or of lupulin in the average dose of this tincture is too small to produce much effect beyond that of the alcohol it contains. A draught of malt liquor would generally be preferable. The *dose* is from 1 to 3 fluidrachms (Gm. 4–12).

TINCTURA HYDRASTIS, U. S.—TINCTURE OF HYDRASTIS.*Teinture de hydrastis, Fr.; Hydrastistinktur, G.*

Preparation.—Hydrastis, in No. 60 powder, 20 parts (6 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 15 parts (4½ oz. av. or 4½ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—*U. S.*

This is a new tincture, which has a brown-yellow color and bitter taste. A menstruum stronger in alcohol would render the tincture more permanent.

Medical Uses.—Probably this tincture fully represents hydrastis. Its dose is yet to be determined, but provisionally may be stated at a fluidrachm (Gm. 4).

TINCTURA HYOSCYAMI, U. S., Br.—TINCTURE OF HYOSCYAMUS.*Teinture de jusquiame, Fr.; Bilsenkrauttinktur, G.*

Preparation.—Hyoscyamus, recently dried and in No. 60 powder, 15 parts (4½ oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 15 parts (4½ oz. av. or 4½ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 30 fluidounces) of tincture are obtained.—*U. S.*

Hyoscyamus-leaves, in coarse powder, 2½ oz. av., proof spirit sufficient for 1 Imperial pint.—*Br.* Hyoscyamus 1 part, alcohol (sp. grav. .912) 5 parts.—*F. Cod.*

The tincture is greenish-brown, and has the narcotic odor of the leaves and a bitter taste.

Medical Uses.—The tincture is generally believed to contain all the virtues of hyoscyamus, and is directed to be given in the *dose* of a fluidrachm (Gm. 4). But, according to Mr. Boulter's experiments (*St. Bartholomew's Reports*, xv. 224), the tinctures of the leaves and seeds are practically quite useless, although they occasion some dilatation of the pupils and render the pulse weak, irregular, and intermittent. The tincture of the root, on the other hand, in doses of from ½ to 2 fluidrachms, produced dryness of the mouth and fauces, with thirst, flushed face, cracked lips, and sometimes delirium.

TINCTURA IGNATIÆ, U. S.—TINCTURE OF IGNATIA.*Teinture de fève de Saint Ignace, Fr.; Ignazbohrentinktur, G.*

Preparation.—Ignatia, in No. 60 powder, 10 parts (3 oz. av.); Alcohol, Water, each a sufficient quantity. Mix alcohol and water in the proportion of 8 parts (32 oz.

av. or $37\frac{1}{2}$ fluidounces) of alcohol to 1 part (4 oz. av. or $3\frac{1}{2}$ fluidounces) of water. Moisten the powder with 10 parts (3 oz. av. or $3\frac{1}{2}$ fluidounces) of the menstruum, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it until the ignatia is exhausted. Reserve the first 90 parts (27 oz. av.) of the percolate; evaporate the remainder to 10 parts (3 oz. av.) and mix with the reserved portion. Of this tincture take any convenient number of parts, and by means of a water-bath evaporate it to dryness. Weigh the resulting extract, and from its weight calculate the quantity of extract contained in the 100 parts of tincture obtained; then dissolve the dried extract in the remainder of the tincture, and add enough of the above menstruum to make the product weigh so many parts that each 100 parts of tincture shall contain 1 part of dry extract. Lastly, mix thoroughly and filter through paper. Tincture of ignatia thus prepared represents about 10 parts (3 oz. av.) of ignatia in 100 parts (30 oz. av. or about 34 fluidounces).—*U. S.*

The object of this process is to have the tincture always approximately of uniform strength; to secure this result it is absolutely necessary to closely adhere to the alcoholic strength of the menstruum, since variation therein is accompanied by variation in the amount of extract, though not in that of the alkaloids. If extract of ignatia is on hand which has been prepared with alcohol of the strength indicated, the tincture may be made by dissolving 1 part (or 40 grains) of it in 99 parts (or 9 oz. av. = $10\frac{1}{4}$ fluidounces) of the menstruum. (For further remarks on standardizing this tincture see TINCTURA NUCIS VOMICÆ.)

Medical Uses.—Like the tincture of *nux vomica*, this preparation is chiefly used to reinforce other bitter tonics or to represent the minutest doses of the alkaloids it contains. *Dose*, 5 to 20 minims (Gm. 0.30–1.20).

TINCTURA IODI, *U. S., Br., F. Cod., P. G.*—TINCTURE OF IODINE.

Tinctura iodinii, *U. S.* 1870.—*Teinture d'iode*, *Fr.*; *Jodtinktur*, *G.*

Preparation.—Iodine 8 parts ($\frac{1}{2}$ oz. av.); Alcohol 92 parts ($5\frac{3}{4}$ oz. av. or $6\frac{3}{4}$ fluidounces); to make 100 parts ($6\frac{1}{4}$ oz. av. or about 7 fluidounces). Dissolve the iodine in the alcohol.—*U. S.*

Iodine $\frac{1}{2}$ oz. av., iodide of potassium $\frac{1}{2}$ oz. av., rectified spirit 1 pint (Imperial).—*Br.* Iodine 1 part, alcohol (spec. grav. .833) 12 parts, *F. Cod.* (10 parts, *P. G.*).

The tincture has a deep brown-red color and the odor of iodine, evaporates completely without leaving any fixed residue (that of *Br. P.* leaves KI), and yields a precipitate of iodine on being mixed with water. The iodine gradually reacts with the alcohol at ordinary temperatures, and more rapidly at a somewhat elevated temperature, resulting in the formation of hydriodic acid and other compounds, which prevent the precipitation by water of some of the iodine. According to Guibourt, after the tincture has been kept on hand for about eighteen months it is scarcely rendered turbid by water. The tincture should therefore be made in moderate quantities only, or, according to Castelhaz (1882), may be preserved of proper strength by the addition of one-half of 1 per cent. of potassium iodate, which salt is insoluble in alcohol and regenerates iodine from the hydriodic acid formed; at the same time, however, a corresponding quantity of iodate is converted into iodide; $KIO_3 + 6HI$ yield $3I_2 + KI + 3H_2O$. According to Pavesi (1883), chloral hydrate dissolves in tincture of iodine without decomposition, and renders it miscible with water without precipitation. The tincture should be kept in well-stopped bottles to prevent the evaporation of alcohol.

Tests.—"6.33 Gm. of the tincture, mixed with a solution of 2 Gm. of iodide of potassium in 25 Cem. of water and a little gelatinized starch, should require for complete decoloration 40 Cem. of the volumetric solution of hyposulphite of sodium."—*U. S.* This test indicates 8 per cent. of free iodine, and is perfectly correct for the freshly-prepared tincture, but entirely too rigorous for that which has been kept on hand for some time. The same test has been adopted by the *P. G.*; but, while the freshly-made tincture contains 9.09 per cent. of free iodine, the tincture is regarded as being of good quality if the iodine has been reduced to 8.78 per cent. The French Codex directs the tincture to be recently made, without further indicating the limit of time.

Off. Prep.—Vapor iodi, *Br.*

Allied Tinctures.—TINCTURA IODI DECOLORATA. Digest 10 parts each of iodine, hyposulphite of sodium, and water until solution has been effected; then add 16 parts of ammoniated alcohol and 75 parts of alcohol. After setting the mixture aside for two or three days it becomes colorless and is ready for use.—*P. G.* 1872. It has a somewhat ethereal and feebly ammoniacal odor,

and contains *iodide of ammonium*, *iodide of ethyl* (C_2H_5I), and *hydriodate of triethylamine* ($C_6H_{15}NI$); the latter compound is gradually converted into iodide of ethyl and triethylamine. In addition to these compounds the tincture contains also a little iodide and sulphate of sodium, which are not present if the tincture is made as originally proposed (1869) by Dr. C. O. Curtman (iodine 10 drachms, alcohol 13 fluidounces, stronger ammonia-water 3 fluidounces). In the latter case, however, about 27 days are required for effecting complete decoloration.

TINCTURA IODINII COMPOSITA, COMPOUND TINCTURE OF IODINE. Dissolve iodine 240 grains and iodide of potassium 480 grains in alcohol 1 pint.—*U. S.* 1870. This tincture resembles the simple tincture of iodine in appearance, but differs from it in being miscible with water without causing precipitation. The British *Tinctura iodi* likewise contains potassium iodide, but in insufficient quantity to prevent its precipitation by water, at least when recently made.

Medical Uses.—They are set forth at length under **IODUM**. This preparation is unsuited for internal administration, since the addition of water precipitates its iodine. The compound tincture, which is no longer official, is to be preferred for this purpose. The *dose* of the simple tincture is from 5 to 15 drops (Gm. 0.30–1). It may be given largely diluted with water properly flavored.

Decolorized tincture of iodine is, as above pointed out, no longer a tincture of iodine, and is practically of no more value as a local discutient than a solution of iodide of sodium or ammonium in water.

The compound tincture (1870) is not precipitated by water, and is also more permanent than the simple tincture, as well as less irritating and more absorbable. It is greatly to be preferred for internal use. The *dose* is from 10 to 30 drops (Gm. 0.60–2), largely diluted with water or some mild liquid.

TINCTURA IPECACUANHÆ ET OPII, *U. S.*—TINCTURE OF IPECACUANHA AND OPIUM.

Preparation.—Deodorized Tincture of Opium 100 parts (10 oz. av.); Fluid Extract of Ipecac 10 parts (1 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (10 oz. av.). Evaporate the deodorized tincture of opium on a water-bath until it weighs 85 parts (8½ oz. av.). When it has become cold add to it the fluid extract of ipecac: filter the mixture and pass enough diluted alcohol through the filter to make the tincture weigh 100 parts (10 oz. av. or about 10 fluidounces).—*U. S.*

This tincture has been admitted into the Pharmacopœia to take the place of similar preparations which have been used to some extent under the designation of *tincture of Dover's powder*.

Medical Uses.—The virtues of this new preparation, which is apparently intended to present Dover's powder in a liquid form, are not very evident. If, as generally has been supposed, the gradual solution and absorption of the opium and ipecac in that preparation has much to do with its diaphoretic operation, then in the liquid form the object is less likely to be attained. And it is difficult to understand why an extemporaneous mixture of deodorized tincture of opium and wine of ipecac would not have answered the same purpose as this new official formula.

TINCTURA JALAPÆ, *Br.*—TINCTURE OF JALAP.

Trinture de jalap, Fr.; *Jalapentinktur*, G.

Preparation.—Macerate and displace coarsely-powdered jalap 2½ oz. av. with sufficient proof spirit to obtain 1 pint (Imperial).—*Br.*

Jalap 1 part, alcohol (sp. grav. .912) 5 parts.—*F. Cod.*

Medical Uses.—This tincture is seldom used except as an addition to other purgative liquids. The *dose* is from ½ fluidrachm to 2 fluidrachms (Gm. 2–8).

TINCTURA KINO, *U. S.*, *Br.*—TINCTURE OF KINO.

Teinture de kino, Fr.; *Kinotinktur*, G.

Preparation.—Kino 10 parts (1 oz. av.); Glycerin 15 parts (1½ oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 parts (10 oz. av.). Mix the glycerin with 60 parts (6 oz. av. or 7 fluidounces) of alcohol, and 15 parts (1½ oz. av. or 11½ fluidrachms) of water. Rub the kino in a mortar, adding gradually 30 parts (3 oz. av.) of this menstruum until a smooth paste is made; transfer this to a bottle, add the remainder of the menstruum, and macerate for 24 hours, occasionally shaking the bottle; then filter through paper, adding, through the filter, enough of a mixture of alcohol and

water, made in the proportion of 4 parts (5 fluidrachms) of alcohol and 1 part (1 fluidrachm) of water, to make the tincture weigh 100 parts (10 oz. av. or about 10 fluidounces). Keep the tincture in well-stopped bottles.—*U. S.*

Kino in coarse powder 2 ounces; glycerin 3 fluidounces; distilled water 5 fluidounces; rectified spirit 12 fluidounces. Macerate for 7 days in a closed vessel, with occasional agitation; filter and add sufficient alcohol to make 1 pint (Imperial).—*Br.* Macerate for 10 days kino 1 part with alcohol (sp. grav. .913) 5 parts, and filter.—*F. Cod.*

Tincture of kino is conveniently prepared by maceration, and has a dark brown-red color. Made with alcohol and properly preserved, it will remain limpid, but if made with diluted alcohol it will gradually lose its astringency and become gelatinous. According to P. P. Fox (1877), this may be prevented, without increasing the alcoholic strength, by replacing one-half of the water with an equal measure of glycerin—a fact noticed by Haselden as early as 1860; and this is substantially the process adopted by the present U. S. Pharmacopœia. The employment of magnesia, logwood, and other foreign substances with the same end in view is objectionable and unnecessary. The origin of kino, and probably also its age, may influence the tendency to gelatinize.

Medical Uses.—This tincture is used for most of the internal purposes of kino in the dose of 1 or 2 fluidrachms (Gm. 4–8). When made according to the formula of 1870, it tended to gelatinize in watery mixtures. The presence of glycerin in the present tincture is supposed to remedy that defect, but perhaps at the expense of the astringency of the preparation.

TINCTURA KRAMERLÆ, *U. S., Br.*—TINCTURE OF KRAMERIA.

Tinctura ratanhizæ, P. G.—*Tincture of rhatany*, E.; *Teinture de ratanhia*, Fr.; *Ratanhatinktur*, G.

Preparation.—Krameria, in No. 40 powder, 20 parts (6 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 20 parts (6 oz. av. or 6½ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—*U. S.*

Rhatany 2½ oz. av., proof spirit sufficient for 1 pint (Imperial).—*Br.* Macerate rhatany 1 part in 5 parts of alcohol sp. grav. .912, *F. Cod.* (sp. grav. .894, *P. G.*).

This tincture has a brown-red color and a strongly astringent taste. After having been kept in partly-filled bottles it deposits rhatany-red, and occasionally gelatinizes. It is therefore best prepared in small quantities.

Medical Uses.—This is the form in which rhatany is perhaps more frequently used than any other astringent in the treatment of subacute *diarrhœa*. For this purpose it is usually added to the chalk mixture. Diluted with water, it forms a very useful mouth-wash when the *gums* are spongy. It has also been reputed serviceable in atonic *menorrhagia* and in other forms of passive *hæmorrhage*. The dose is 1 or 2 fluidrachms (Gm. 4–8).

TINCTURA LARICIS, *Br.*—TINCTURE OF LARCH.

Teinture d'écorce de mélèze, Fr.; *Lärchenrindentinktur*, G.

Preparation.—Take of Larch-Bark, in No. 40 powder, 2½ oz. av.; Rectified Spirit 1 pint. Prepare 1 pint (Imperial) of tincture by the formula given under TINCTURÆ.—*Br.*

This tincture has a red-brown color, and should be carefully preserved like other astringent tinctures.

Medical Uses.—Tincture of larch-bark is not employed in this country. It has been used in England as a remedy for passive *hæmorrhages*, *purpura*, and *chronic bronchitis*. The dose is from 20 to 30 minims (Gm. 1.30–2).

TINCTURA LAVANDULÆ COMPOSITA, *U. S., Br.*—COMPOUND TINCTURE OF LAVENDER.

Spiritus lavandulæ compositus, U. S. 1870.—*Compound spirit of lavender*, *Lavender drops*, E.; *Teinture de lavande composée*, Fr.; *Zusammengesetzte Lavendeltinktur*, G.

Preparation.—Oil of Lavender 8 parts (½ oz. av. or 4½ fluidrachms); Oil of Rosemary 2 parts (⅓ oz. av. or 65 minims); Cinnamon, in coarse powder, 18 parts (1½ oz.

av.); Cloves 4 parts ($\frac{1}{4}$ oz. av.); Nutmeg 10 parts ($\frac{1}{2}$ oz. av. = 274 grains); Red Saunders, in coarse powder, 8 parts ($\frac{1}{4}$ oz. av.); Alcohol 680 parts (42 $\frac{1}{2}$ oz. av. or 49 $\frac{1}{2}$ fluidounces); Water 270 parts (16 $\frac{3}{4}$ oz. av. or 16 $\frac{1}{4}$ fluidounces); Diluted Alcohol a sufficient quantity; to make 1000 parts (62 $\frac{1}{2}$ oz. av.). Dissolve the oils in the alcohol and add the water. Crush the nutmeg in a mortar, mix it with the cinnamon, cloves, and red saunders, and reduce the mixture by grinding to a coarse (No. 20) powder. Moisten the mixture with a sufficient quantity of the alcoholic solution of the oils, pack it firmly in a cylindrical percolator, gradually pour upon it the remainder of the alcoholic solution, and afterward sufficient diluted alcohol, until 100 parts (62 $\frac{1}{2}$ oz. av. or about 4 $\frac{1}{4}$ pints) of tincture are obtained.—*U. S.*

Take of oil of lavender 1 $\frac{1}{2}$ fluidrachms; oil of rosemary 10 minims; cinnamon-bark, bruised, nutmeg, bruised, each 150 grains; red sandal-wood 300 grains; rectified spirit 2 pints (Imperial). Macerate the cinnamon, nutmeg, and red sandal-wood in the spirit for 7 days in a closed vessel, with occasional agitation; then strain and press, dissolve the oils in the strained tincture, filter, and add sufficient rectified spirit to make 2 pints.—*Br.*

The tincture of the first formula is stronger in volatile oils and aromatics than that made by the second formula. Both have a red color, form opalescent mixtures with water, and, if prepared from good materials, have an agreeable odor and a strong but pleasant aromatic taste.

Off. Prep.—Liquor potassii arsenitis (Liq. arsenicalis), *U. S.*, *Br.*

Medical Action and Uses.—Of the numerous ingredients in this popular and useful compound, oil of lavender, except by its disproportionate quantity, is one of the least active and efficient. It is universally employed in this country as a domestic cordial remedy for *nausea*, *flatulent colic*, and gastric distress after food. It is most conveniently administered on a lump of sugar or in a little hot and sweetened water. The *dose* is from half a fluidrachm to a fluidrachm (Gm. 2–4).

TINCTURA LIMONIS, *Br.*—TINCTURE OF LEMON-PEEL.

Teinture de zeste de citron (limon), Fr.; *Citronenschalentinktur*, G.

Preparation.—Take of Fresh Lemon-Peel, sliced thin, 2 $\frac{1}{2}$ oz. av.; Proof Spirit 1 pint. Macerate for 7 days in a closed vessel, with occasional agitation; strain, press, and filter; then add sufficient proof spirit to make 1 pint (Imperial).—*Br.*

Medical Uses.—Tincture of lemon-peel is used for flavoring mixtures, etc. *Dose*, a fluidrachm (Gm. 4).

TINCTURA LOBELIÆ, *U. S.*, *Br.*, *P. G.*—TINCTURE OF LOBELIA.

Teinture de lobélie enflée, Fr.; *Lobeliatinktur*, G.

Preparation.—Lobelia, in No. 40 powder, 20 parts (6 oz.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 20 parts (6 oz. av. or 6 $\frac{1}{4}$ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—*U. S.*

Lobelia 2 $\frac{1}{2}$ oz. av., proof spirit sufficient for 1 pint (Imperial).—*Br.* Lobelia 1 part, alcohol (spec. grav. .912) 5 parts.—*F. Cod.* Lobelia 1 part, alcohol (spec. grav. 0.894) 10 parts.—*P. G.*

The tincture is of a green-brown color and has a somewhat heavy odor and a bitter and acrid taste.

Medical Uses.—Lobelia is most frequently prescribed under the form of this tincture. Its *dose* as an expectorant is from 10 minims to a fluidrachm (Gm. 0.60–4). In asthmatic attacks 1 or 2 fluidrachms (Gm. 4–8) should be administered every half hour or hour.

TINCTURA LOBELIÆ ÆTHEREA, *Br.*—ETHEREAL TINCTURE OF LOBELIA.

Preparation.—Take of Lobelia, in coarse powder, 2 $\frac{1}{2}$ oz. av.; Spirit of Ether 1 pint. Macerate for 7 days in a closed vessel, with occasional agitation; then strain, press, filter, and add sufficient spirit of ether to make 1 pint (Imperial).—*Br.*

It is of a brownish-green color.

Medical Uses.—This preparation is perhaps more efficient than the simple tincture in *asthma*. The *dose* is from 10 to 30 minims (Gm. 0.60–2).

TINCTURA MATICO, U. S.—TINCTURE OF MATICO.

Teinture de matico, Fr.; *Maticotinktur*, G.

Preparation.—Matico, in No. 40 powder, 10 parts (3 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the matico with 10 parts (3 oz. av. or 3½ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—*U. S.*

This tincture has been newly admitted into the Pharmacopœia. It is about one-tenth the strength of the fluid extract, and, being made with a weaker alcohol, is of a greenish-brown color. The following formula yields a brown-green tincture: Matico 1 part, alcohol (spec. grav. .863) 5 parts.—*F. Cod.*

Medical Uses.—In nearly all the affections in which matico is used alcohol is contraindicated, and hence it would seem that the already official fluid extract of matico was sufficient without a tincture. Of the new preparation the dose may be stated at 1 or 2 fluidrachms (Gm. 4–8).

TINCTURA MOSCHI, U. S., P. G.—TINCTURE OF MUSK.

Teinture de musc, Fr.; *Moschustinktur*, G.

Preparation.—Musk 10 parts (1 oz. av.); Alcohol 45 parts (4½ oz. av. or 5½ fluidounces); Water 45 parts (4½ oz. av. or 4½ fluidounces); Diluted Alcohol a sufficient quantity; to make 100 parts (10 oz. av.). Rub the musk in a mortar first with a little of the water, until a smooth mixture is made, and then with the remainder of the water. Transfer the whole to a bottle, add the alcohol, and macerate the mixture for 7 days, occasionally shaking the bottle. Then filter through paper, adding, through the filter, enough diluted alcohol to make the tincture weigh 100 parts (10 oz. av. or about 10 fluidounces).—*U. S.*

Musk 10 parts, alcohol (spec. grav. .863) 100 parts.—*F. Cod.* Musk 2 parts, water and alcohol (spec. grav. .894), of each 50 parts.—*P. G.*

The manipulation described above is the same as directed by the German Pharmacopœia, but the strength of the alcohol and the proportion of musk differ considerably. Strong alcohol gives a light-brown tincture, which becomes slightly opalescent with water; but weak alcohol yields a dark reddish-brown tincture, which has a strong musk odor and remains clear on the addition of water.

Medical Uses.—This preparation will be found convenient for the rare occasions in which musk is used medicinally. The alcoholic menstruum promotes its action. Every 10 minims of the tincture contains about 1 grain of musk. *Dose*, about 1 fluidrachm (Gm. 4).

TINCTURA MYRRHÆ, U. S., Br., P. G.—TINCTURE OF MYRRH.

Teinture de myrrhe, Fr.; *Myrrhentinktur*, G.

Preparation.—Myrrh, in moderately coarse powder, 20 parts (6 oz. av.); Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Mix the powder with 80 parts (24 oz. av. or 28 fluidounces) of alcohol, and macerate for 7 days in a closed vessel; then filter through paper, adding, through the filter, enough alcohol to make the tincture weigh 100 parts (30 oz. av. or about 34 fluidounces).—*U. S.*

Myrrh 2½ oz. av., rectified spirit sufficient for 1 pint (Imperial).—*Br.* Myrrh 1 part, alcohol spec. grav. .863 (*F. Cod.*) (or .832, *P. G.*) 5 parts.

The tincture is of a brownish-yellow or reddish-yellow color, has the balsamic odor of myrrh and a bitter aromatic taste, and yields a precipitate of resin on the addition of water. E. B. Shuttleworth (1871) suggested the utilization of the gum left on preparing the tincture for making a mucilage, by dissolving it in boiling water, straining, and allowing to settle. The adhesive properties are increased by the addition of a small quantity of molasses.

Medical Uses.—Tincture of myrrh is seldom used internally, but it may be prescribed in *doses* of from 30 minims to a fluidrachm (Gm. 2–4). It is chiefly used as a stimulant, astringent, and protective agent in the treatment of *aphthæ*, *spongy gums*,

relaxed *urula*, aphthous affections of the *vagina*, etc. In these cases it is generally diluted with water, which precipitates its resin. Campardon (1879) reports that "*whooping cough* yields easily and promptly to tincture of myrrh administered in 'wine of cinchona.'" He prescribes it in doses of 10 drops or of 5 drops every hour, according to the age of the patient, and asserts that in every one of numerous cases it destroyed the spasmodic element of the cough in a few days (*Bull. de thérap.*, xcv. 193).

TINCTURA NUCIS VOMICÆ, U. S., Br.—TINCTURE OF NUX VOMICA.

Tinctura strychni, P. G.—*Teinture de noix vomique*, Fr.; *Krähenaugentinktur*, G.

Preparation.—Nux Vomica, in No. 40 powder, 20 parts (6 oz. av.); Alcohol, Water, each a sufficient quantity. Mix alcohol and water in the proportion of 8 parts (32 oz. av. or 37½ fluidounces) of alcohol to 1 part (4 oz. av. or 3½ fluidounces) of water. Moisten the powder with 20 parts (6 oz. av. or 6½ fluidounces) of the menstruum, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it until the nux vomica is exhausted. Reserve the first 90 parts (27 oz. av. or about 30 fluidounces) of the percolate; evaporate the remainder to 10 parts (3 oz. av.) and mix with the reserved portion. Of this tincture take any convenient number of parts, and by means of a water-bath evaporate to dryness; weigh the resulting extract, and from its weight calculate the quantity of dry extract contained in the 100 parts of tincture; then dissolve the dried extract in the remainder of the tincture, and add enough of the above menstruum to make the product weigh so many parts that each 100 parts of tincture shall contain 2 parts of dry extract. Lastly, mix thoroughly and filter through paper. Tincture of nux vomica thus prepared represents about 20 parts (6 oz. av.) of nux vomica in 100 parts (30 oz. av. or about 34 fluidounces).—U. S.

Dissolve extract of nux vomica, 133 grains, in distilled water 4 fluidounces and rectified spirit sufficient for 20 fluidounces.—Br. This formula has been adopted in accordance with the investigations of Dunstan and Short, noticed below.

Rasped nux vomica 1 part, alcohol (sp. gr. .863) 5 parts.—F. Cod. Nux vomica 1 part, alcohol (sp. gr. 0.894) 10 parts.—P. G.

TINCTURA STRYCHNI ÆTHEREA. Coarsely-powdered nux vomica 1 part, spirit of ether 10 parts. Macerate for 8 days, express, and filter.—P. G. 1872.

These tinctures have a yellowish color and a very bitter taste, and become opalescent when mixed with water. A few drops of the tincture, evaporated to dryness, leave a brownish-yellow residue, which is colored yellowish-red by nitric acid. The tough nature of the drug necessitates its prolonged maceration or digestion with the menstruum, and the firm packing in case the tincture is prepared by percolation. R. Rother (1883) noticed that the horny matter of nux vomica is speedily softened by sodium chloride, without becoming in the least mucilaginous, and proposes the addition of ¼ oz. of the salt for 8 oz. of the drug; a portion of the salt may be mixed with the powder, and the remainder dissolved in the water before the alcohol is added. G. W. Kennedy (1870) observed the separation of crystals of strychnine from a tincture which had been prepared with nux vomica, yielding an aqueous infusion of an alkaline reaction.

The first formula is an attempt at standardizing this important tincture, the strength being adjusted by the amount of extract, as is also directed for tincture of *ignatia*. We have stated elsewhere (p. 651) that the percentage of extract obtained from the drug varies considerably with the alcoholic strength of the menstruum, strong alcohol yielding less and weak alcohol more extract from the same sample of nux vomica. The tincture should therefore never be prepared from the extract unless the latter has been made in strict conformity with the Pharmacopœia—i. e. with the same menstruum directed for the tincture. ½ oz. av. of such extract dissolved in 24½ oz. av. or 27½ fluidounces of alcohol spec. grav. .846 will yield the pharmacopœial tincture.

The percentage of alkaloids contained in nux vomica is not constant (see p. 1024), and even the relative amount of strychnine and brucine varies in different specimens. Investigations made by W. R. Dunstan and F. W. Short (1883–84) show that it is perfectly feasible to obtain pharmaceutical preparations of nux vomica containing a definite amount of total alkaloids, and they propose an extract which should contain 15 per cent. of these alkaloids, and a tincture containing 1 grain of alkaloids in 1 Imperial fluidounce. Accepting the standard extract, 500 grains of the tincture (U. S. P.), containing 10 grains of extract, should contain 1.5 grains of alkaloids, and may be assayed by Dunstan and Short's process as follows: Evaporate the tincture over a water-bath almost to dry-

ness; dissolve the residue in 2 fluidrachms of chloroform and $\frac{1}{2}$ fluidounce of dilute sulphuric acid, mixed with an equal bulk of water; when the liquids have separated draw off the chloroform, add to the acid liquid ammonia in excess and $\frac{1}{2}$ fluidounce of chloroform; well agitate, gently warm, transfer the clear chloroform to a weighed dish, evaporate, dry at 100° C. (212° F.) for one hour, allow to cool, and weigh.

Medical Uses.—This is a very convenient form for the exhibition of *nux vomica*, especially in small doses, although it is of uncertain strength. It is particularly adapted for use in *atonic dyspepsia*. *Dose*, from 5 to 20 minims (Gm. 0.30–130).

TINCTURA OPII, U. S., Br.—TINCTURE OF OPIUM.

Tinctura opii simplex, P.G.—*Tinctura extracti opii*, Fr. Cod.; *Tinctura thebaica*, *Tinctura meconii*.—*Laudanum*, E.; *Teinture d'extrait d'opium*, *Teinture thébétique*, Fr.; *Einfache Opiumtinktur*, G.

Preparation.—Powdered Opium 10 parts (4 oz. av.); Water 40 parts (16 oz. av. or 15 $\frac{1}{2}$ fluidounces); Alcohol 40 parts (16 oz. av. or 19 $\frac{3}{4}$ fluidounces); Diluted Alcohol a sufficient quantity; to make 100 parts (40 oz. av.). Rub the opium in a mortar with the water, previously heated to the temperature of 90° C. (194° F.), until a smooth mixture is made, and macerate for 12 hours; then add the alcohol, mix thoroughly, and transfer the whole to a conical percolator. Return to the percolator the first portion of percolate until it becomes clear, and when the liquid ceases to drop gradually pour on diluted alcohol, continuing the percolation, until 100 parts (40 oz. av. or about 40 fluidounces) of tincture are obtained.—U. S.

Take of opium, in coarse powder, 1 $\frac{1}{2}$ oz. av., proof spirit 1 pint. Macerate for 7 days in a closed vessel, with occasional agitation; then strain, press, filter, and add sufficient proof spirit to make 1 pint (Imperial). It contains the soluble matter of 33 grains of opium nearly, or about 3.3 grains of morphine in 1 fluidounce.—Br.

Powdered opium 1 part, alcohol sp. grav. 0.894 and distilled water, each 5 parts.—P. G. Extract of opium 10 parts, alcohol (sp. gr. 0.912) 120 parts.—F. Cod.

Each fluidrachm (U. S. measure) of these tinctures represents 4.3 grains (Br.), 5.5 grains (U. S. against 4.7 grains, U. S. 1870), and 5.3 grains (P. G.) of dry opium, and 4 grains (F. Cod.) of extract of opium. Calculating 60 per cent. as the yield of extract from dry opium, 1 grain of powdered opium is represented by 9 minims (F. P.), 11.3 minims (P. G.), 11 minims (U. S. against 12.8 minims, U. S. 1870), and 14 minims (Br.), U. S. measure, of these tinctures. The powdered or dry opium used is directed to contain of morphine 12 to 16 per cent. (U. S.), about 10 per cent. (at least 6 to 8 per cent. for crude opium, Br.), at least 10 to 12 per cent. (F. Cod.), 10 per cent. (P. G.).

With due care, opium is readily exhausted by weak alcohol, about 60 per cent. of its constituents being soluble in that menstruum. To ensure uniformity of strength in this important preparation, the opium employed in making it should be well dried, of full morphine strength, and sufficiently long macerated or digested in the menstruum to be completely disintegrated at least a day before it is transferred to a percolator or filter. The residue after drying should yield nothing to water, and dilute acids should dissolve from it only minute quantities of alkaloid compounds. The color of the tincture is deep reddish-brown. It has the narcotic odor and bitter taste of opium, and should be preserved in well-stopped bottles to prevent evaporation of the alcohol.

The term *laudanum* is still recognized by several European pharmacopœias as a synonym for opium. In connection with various epithets (antihystericum, diureticum, etc.) it was formerly employed to designate numerous solid compound preparations of opium, while the stronger liquid opiates were called *laudanum liquidum*, and distinguished by other epithets—tincture of opium, for instance, as *laudanum liquidum simplex*. However, in the United States and Great Britain the tincture is popularly known as laudanum.

Off. Prep.—Enema opii, Linimentum opii, Br.; Mistura magnesiæ et asafœtidæ, U. S.

Allied Tinctures.—TINCTURA OPII ACETATA, U. S. 1870. Dry powdered opium 2 troyounces, distilled vinegar 12 fluidounces, alcohol $\frac{1}{2}$ pint; macerate for a week, express, and filter. The yield is about 20 fluidounces, and 10 minims contain 1 grain of opium. This tincture is now rarely used.

TINCTURA OPII MURIATICA. Macerate for 2 weeks powdered opium 1 ounce, hydrochloric acid 1 ounce, and distilled water 20 ounces; filter (Nichol). This is half the strength of laudanum and contains no alcohol.

Medical Uses.—The simple tincture of opium—or laudanum, as it is distinctively called—possesses most of the good and evil qualities of pure opium. Of the latter the most

conspicuous is its tendency to nauseate. This operation is supposed to depend upon the narcotine which it contains, and which is removed in the process for making the deodorized tincture. The latter is therefore preferable for internal administration, but laudanum forms a convenient addition to liniments, poultices, and other external anodyne applications. It should be remembered that by being kept in imperfectly stoppered vials it becomes relatively stronger by the evaporation of its alcohol. The *dose* for an adult is about 25 drops or 13 minims (Gm. 1), equivalent to about 1 grain of opium.

TINCTURA OPII AMMONIATA, *Br.*—AMMONIATED TINCTURE OF OPIUM.

Teinture d'opium ammoniacale, Fr.; Ammoniakalische Opiumtinktur, G.

Preparation.—Take of Opium in coarse powder. 100 grains; Saffron, cut small, Benzoic Acid, each 180 grains; Oil of Anise 1 fluidrachm; Strong Solution of Ammonia 4 fluidounces; Rectified Spirit 16 fluidounces. Macerate for 7 days in a well-closed vessel, with occasional agitation; then strain, press, filter, and add sufficient rectified spirit to make 1 pint (Imperial).—*Br.*

This is a slight modification of the formula formerly recognized by the Edinburgh Pharmacopœia. The preparation was known as *elixir paregoricum scoticum*, and in Scotland employed as paregoric elixir. It contains the opium alkaloids in a free state, dissolved by the aid of alcohol and of an excess of ammonia. 90 minims of it represent very nearly 1 grain of opium.

Medical Uses.—This preparation, sometimes called Scotch paregoric, is composed of nearly the same ingredients as ordinary paregoric, except that in it ammonia takes the place of the camphor in that preparation. The *dose* is from half a fluidrachm to a fluidrachm (Gm. 2-4).

TINCTURA OPII CAMPHORATA, *U. S.*—CAMPHORATED TINCTURE OF OPIUM.

Tinctura camphoræ composita, Br.; Tinctura extracti opii camphorata, F. Cod.; Tinctura opii benzoica, P. G.; Elixir paregoricum.—Paregoric elixir, E.; Elixir parégorique, Teinture d'opium camphrée, Fr.; Benzoësäurehaltige Opiumtinktur, G.

Preparation.—Powdered Opium 4 parts (44 grains); Benzoic Acid 4 parts (44 grains); Camphor 4 parts (44 grains); Oil of Anise 4 parts (44 grains or 47 minims); Glycerin 40 parts (440 grains or 1 oz. av.); Diluted Alcohol a sufficient quantity; to make 1000 parts (11,000 grains = 25½ oz. av.). Add 900 parts (9900 grains = 22½ oz. av. or 23½ fluidounces) of diluted alcohol to the other ingredients, contained in a suitable vessel, and macerate for 7 days, frequently stirring; then filter through paper in a well-covered funnel, and pass enough diluted alcohol through the filter to make the product weigh 1000 parts (25½ oz. av. or about 25½ fluidounces).—*U. S.*

Opium, in coarse powder, benzoic acid, each 40 grains; camphor 30 grains; oil of anise ½ fluidrachm; proof spirit 1 pint (Imperial).—*Br.* Extract of opium, benzoic acid, oil of anise, each 3 parts; camphor 2 parts; alcohol (sp. gr. .912) 650 parts.—*F. Cod.* Powdered opium and oil of anise, each 1 part; benzoic acid 4 parts; camphor 2 parts; alcohol (sp. gr. 0.894) 192 parts.—*P. G.*

1 grain of opium is represented in 273 (*U. S.*), 256 (*U. S.* 1870), and 230 (*Br.*) minims (*U. S.* measure), and in 250 (*U. S.*), 200 (*P. G.*), and 132 (*F. Cod.*) grains of the tincture. This tincture has a brownish-yellow color, an anise-like and camphoraceous odor, a sweetish, pungently aromatic, and slightly bitter taste, and an acid reaction; on the addition of water it turns milky. It is an ingredient in *Mistura glycyrrhizæ comp., U. S.*

Allied Preparations.—The following formulas were adopted by the Philadelphia College of Pharmacy (1833) for the nostrums named:

BATEMAN'S PECTORAL DROPS. Digest for 24 hours rasped red saunders 2 troyounces in 4 gallons of diluted alcohol; filter, and add powdered opium, catechu, and camphor, each 2 troyounces, oil of anise 4 fluidrachms. Digest for 10 days and filter. It is of the same opium strength as paregoric.

GODFREY'S CORDIAL. Dissolve carbonate of potassium 2½ troyounces in water 26 pints; add sugar-house molasses 16 pints; heat the mixture over a gentle fire until it simmers; remove the scum; add tincture of opium 1½ pints, alcohol 2 pints, and oil of sassafras 4 fluidrachms, previously mixed together. Each fluidounce represents nearly 1½ grains of opium.

Medical Uses.—Camphorated tincture of opium is in common use to relieve *abdom-*

inal pains produced by flatus or by irritability of the stomach or bowels, and for allaying *cough* when there is no active inflammation of the respiratory organs. The *dose* for an adult is 1 or 2 fluidrachms (Gm. 4–8), and for an infant from 5 to 20 drops (Gm. 0.30–1.30). It is usually administered in sweetened water.

TINCTURA OPII DEODORATA, U. S.—DEODORIZED TINCTURE OF OPIUM.

Preparation.—Powdered Opium 10 parts (4 oz. av.); Ether 20 parts (8 oz. av. or 10½ fluidounces); Alcohol 20 parts (8 oz. av. or 9½ fluidounces); Water a sufficient quantity; to make 100 parts (40 oz. av.). Rub the opium in a mortar with 40 parts (16 oz. av. or 15½ fluidounces) of water, gradually added, until thoroughly softened, and macerate for 12 hours; then express, and repeat the operation twice, using the same quantity of water each time. Mix the expressed liquids, evaporate the mixture to 10 parts (4 oz. av. or about 3 fluidounces), and when it has cooled shake it repeatedly with the ether in a bottle. When the ethereal solution has separated by standing, pour it off, and evaporate the remaining liquid until all traces of ether have disappeared. Mix the residue with 50 parts (20 oz. av. or 19½ fluidounces) of water, and filter the mixture through paper. When the liquid has ceased to pass add enough water, through the filter, to make the filtered liquid weigh 80 parts (32 oz. av. or about 29½ fluidounces). Lastly, add the alcohol, and mix them.—*U. S.*

The process differs but little from that of 1870, except that the infusion of opium is concentrated to a nearly syrupy consistence before it is agitated with ether, whereby narcotine and the odorous principle, together with a little coloring matter, are removed. The remaining aqueous liquid is freed from ether by heat, properly diluted with water, filtered, and preserved by the addition of alcohol. T. G. Davis (1877) proposed to shorten the process by boiling the opium with 3 portions of water, each time for half an hour, expressing, evaporating to 4 fluidounces, mixing with an equal bulk of alcohol, filtering from the gummy precipitate, washing the filter with alcohol, evaporating to 4 fluidounces, and then finishing the product as directed by the Pharmacopœia.

This tincture is of the same opium strength (by weight) as laudanum, but rather lighter in color, and, being made with a more aqueous menstruum, is heavier, so that 10.5 minims represent 1 grain of opium. It is nearly identical with *denarcotized tincture of opium*, and takes the place of several preparations which were at one time introduced as *elixirs of opium*.

Off. Prep.—Tinctura ipecacuanhæ et opii, *U. S.*

Allied Preparations.—LIQUOR OPII COMPOSITUS. Opium is exhausted with water, the infusion concentrated, precipitated by alcohol, the clear liquid evaporated to a small bulk equal in weight to that of opium, and agitated with ether. The aqueous liquid, freed from the ether, is diluted with 1 part of its own weight of water, filtered, mixed with 1 part of stronger alcohol, and diluted with water to 5 parts. A portion of this is assayed, and the whole liquid is then mixed with the remaining ingredients in such proportions that 30 Cem. or 1 fluidounce shall contain 6 grains of morphine, 1 Cem. of chloroform, 2 Cem. of acetic ether, and 13 Cem. of stronger alcohol, the remaining liquid being water. As originally suggested by Dr. Squibb, this preparation contained 4 grains of morphine in the fluidounce, but after the appearance of the new Pharmacopœia this amount was increased to 6 grains. (For details see *Amer. Jour. Phar.*, 1870, p. 47.)

BATTLE'S SEDATIVE DROPS. 3 ounces of extract of opium are dissolved in 30 ounces of hot water, and the solution filtered and mixed with 6 ounces of alcohol. This preparation is about 50 per cent. stronger than those above described.

Medical Uses.—The nauseating effects of laudanum are supposed not to be produced by this preparation, which is of the same strength. It may be given in the *dose* of 15 minims (Gm. 1) or 25 drops.

TINCTURA PHYSOSTIGMATIS, U. S.—TINCTURE OF PHYSOSTIGMA.

Teinture de fève du Calabar, Fr.; Kalabarbohmentinktur, G.

Preparation.—Physostigma, in No. 40 powder, 10 parts (3 oz. av.); Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 10 parts (3 oz. av. or 3½ fluidounces) of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it until 100 parts (30 oz. av. or about 35 fluidounces) of tincture are obtained.—*U. S.*

Physostigma 1 part, alcohol (sp. gr. .863) 5 parts.—*F. Cod.*

In view of the fact that physostigmine and its salts when in solution are readily

altered by the influence of light and air (see pp. 1149 and 1152), it is doubtful whether the tincture is a sufficiently stable preparation; it is advisable, therefore, to make it only in small quantities as needed; and since the amount of matter soluble in strong alcohol is quite small (see p. 654), the tincture may very properly be made by maceration. 38 grains of powdered physostigma and 374 grains (or 1 fluidounce) of alcohol should be used, and after sufficient maceration the liquid should be filtered from the dregs without adding more alcohol.

Medical Uses.—This preparation fully represents physostigma. Its commencing dose may be stated at 10 minims (Gm. 0.60).

TINCTURA PYRETHRI, U. S., Br.—TINCTURE OF PYRETHRUM.

Tincture of pellitory, E.; Teinture de pyrêthre, Fr.; Bertramwurzeltinktur, G.

Preparation.—Pyrethrum, in No. 40 powder, 20 parts (6 oz. av.); Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 15 parts (4½ oz. av. or 5¼ fluidounces) of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it until 100 parts (30 oz. av. or about 34 fluidounces) of tincture are obtained.—*U. S.*

Powdered pellitory 4 oz. av., rectified spirit sufficient for 1 pint (Imperial).—*Br.* Pellitory 1 part, alcohol (sp. gr. .863) 5 parts.—*F. Cod.*

It has a brownish-yellow color and a very acrid taste, and on the addition of water becomes opalescent and milky.

Medical Uses.—Tincture of pellitory is not given internally, but is a convenient substitute for the root of the plant as an application to painful cavities in *carious teeth* and as a local stimulant in *paralysis of the tongue, rectum, palati, and pharynx.*

TINCTURA QUASSIÆ, U. S., Br.—TINCTURE OF QUASSIA.

Teinture de quassie amère, Fr.; Quassiatinktur, G.

Preparation.—Quassia, in No. 40 powder, 10 parts (3 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 10 parts (3 oz. av. or 3¼ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—*U. S.*

Quassia-wood, in chips, ¾ oz. av., proof spirit sufficient for 1 pint (Imperial).—*Br.* Quassia 1 part, alcohol (sp. gr. .912) 5 parts.—*F. Cod.*

The tincture has a light brownish-yellow color and a persistently bitter taste, and is not colored black by ferric salts.

Medical Uses.—It is occasionally employed during convalescence from low fevers and other exhausting acute diseases, as well as in various atonic *dyspeptic conditions* of gastric origin; but it is less frequently prescribed alone than as an addition to the infusion of quassia or of other bitter tonics or associated with their tinctures. The average dose is about 1 fluidrachm (Gm. 4). It is sometimes given in enema to destroy rectal *ascarides.*

TINCTURA QUININÆ, Br.—TINCTURE OF QUININE.

Preparation.—Take of Hydrochlorate of Quinine 160 grains; Tincture of Orange-Peel 1 pint (Imperial). Dissolve the hydrochlorate of quinine in the tincture with the aid of a gentle heat; then allow the solution to remain for 3 days in a closed vessel, shaking it occasionally, and then filter.—*Br.*

Medical Uses.—This preparation might very properly have been left to magistral prescription. Each fluidrachm (Gm. 4) contains 1 grain of hydrochlorate of quinine.

TINCTURA QUININÆ AMMONIATA, Br.—AMMONIATED TINCTURE OF QUININE.

Preparation.—Take of Sulphate of Quinia 160 grains; Solution of Ammonia 2½ fluidounces (Imperial); Proof Spirit 17½ fluidounces. Dissolve the sulphate of quinia in the spirit with a gentle heat, and add the solution of ammonia.—*Br.*

Medical Uses.—This association of quinine and ammonia is supposed to be indicated in *neuralgia* and other *nervous affections* due to a want of nervous energy. The dose is from ½ to 1 fluidrachm (Gm. 2-4).

TINCTURA RHEI, U. S., Br.—TINCTURE OF RHUBARB.

Teinture de rhubarbe, Fr.; *Rhabarbertinktur*, G.

Preparation.—Rhubarb 12 parts (3 oz. av.); Cardamom 2 parts ($\frac{1}{2}$ oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (25 oz. av.). Mix the rhubarb and cardamom, and reduce the mixture to a moderately coarse (No. 40) powder; moisten the powder with 10 parts (3 oz. av. or $3\frac{1}{2}$ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (25 oz. av. or about 25 fluidounces) of tincture are obtained.—U. S.

Rhubarb, in coarse powder, 2 oz. av.; cardamom-seeds, freed from the pericarps and bruised, coriander-fruit, bruised, saffron, each $\frac{1}{4}$ oz. av.; proof spirit sufficient for 1 pint (Imperial).—Br.

Rhubarb 1 part and alcohol (sp. gr. .912) 5 parts.—F. Cod.

The tincture is of a deep reddish-brown color, has the odor and taste of rhubarb, becomes turbid with water, and on standing deposits orange-yellow granular crystals, consisting mainly of chrysophanic acid. The use of a stronger alcohol or the addition of glycerin to the menstruum will only partly prevent this precipitation.

Allied Tinctures.—TINCTURA RHEI AQUOSA, P. G. Take of rhubarb, cut into thin pieces, 100 parts; powdered borax, carbonate of potassium, each 10 parts; add boiling distilled water 900 parts, and after 15 minutes alcohol 90 parts; macerate for 1 hour, express slightly, and to 850 parts of liquid add cinnamon-water 150 parts.

TINCTURA RHEI ET ABSINTHII; Tinct. absinthii composita, F. Cod.—Elixir stomachique de Stoughton, Fr.—Rhubarb, gentian, wormwood, germander, and bitter orange-peel, of each 5 parts; aloes and cascarilla, each 1 part; alcohol (sp. gr. .912) 200 parts.—F. Cod. Numerous other formulas for *Stoughton's bitters* have been in use, rhubarb, gentian, and orange-peel being the principal ingredients.

TINCTURA RHEI ET ALOES, s. *Elixir sacrum*. Rhubarb, bruised, 10 drachms, aloes 6 drachms, cardamom 4 drachms, diluted alcohol 2 pints. Macerate for 14 days, express, and filter.—U. S. 1850.

TINCTURA RHEI ET GENTIANÆ, s. *Tinct. rhei amara*. Rhubarb, bruised, 2 troyounces, gentian, bruised, 4 drachms, diluted alcohol 2 pints. Proceed as above.—U. S. 1850.

TINCTURA RHEI ET SENNÆ. Rhubarb 1 troyounce, senna 120 grains, coriander, fennel, each 60 grains, liquorice 30 grains, raisins, deprived of their seeds, 6 troyounces, diluted alcohol 3 pints. Macerate for 7 days, express, and filter through paper.—U. S. 1870. This tincture is known as *Warner's gout cordial* and has a reddish-brown color.

Medical Uses.—Tincture of rhubarb is used to qualify the action of saline purgatives and in *gouty* or other feeble states of the system requiring a stimulant as well as a laxative medicine. Its *dose* is from $\frac{1}{2}$ to 1 fluidounce (Gm. 16–32) as a purgative. As a stomachic it may be given in the dose of about a fluidrachm (Gm. 4).

TINCTURA RHEI AROMATICA, U. S.—AROMATIC TINCTURE OF RHUBARB.

Teinture de rhubarbe aromatique, Fr.; *Aromatische Rhabarbertinktur*, G.

Preparation.—Rhubarb 20 parts (5 oz. av.); Cinnamon 4 parts (1 oz. av.); Cloves 4 parts (1 oz. av.); Nutmeg 2 parts ($\frac{1}{2}$ oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (25 oz. av.). Mix the rhubarb, cinnamon, cloves, and nutmeg, and reduce the mixture to a moderately coarse (No. 40) powder; moisten the powder with 15 parts ($3\frac{1}{2}$ oz. av. or $3\frac{1}{2}$ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (25 oz. av. or about 24 fluidounces) of tincture are obtained.—U. S.

This tincture is for the first time recognized as a distinct preparation, it having formerly been made only for preparing spiced syrup of rhubarb (see p. 489). It has a dark red-brown color, a pleasant aromatic odor, and a spicy and bitter taste; on keeping it deposits some chrysophanic acid and other principles of rhubarb; on the addition of water it becomes turbid.

Off. Prep.—Syrupus rhei aromaticus, U. S.

Medical Uses.—This new official seems to have been intended only for the preparation of the aromatic syrup of rhubarb. It may, however, be added to the number of purgative tinctures which are used in *gouty* and enfeebled states of the system, such as the tinctures of aloes and myrrh or of rhubarb and senna (1870), and indeed may be appropriately administered along with them. *Dose*, 2 to 4 fluidrachms (Gm. 8–16).

TINCTURA RHEI DULCIS, U. S.—SWEET TINCTURE OF RHUBARB.*Teinture de rhubarbe douce, Fr.; Süsse Rhubarbertinktur, G.*

Preparation.—Rhubarb 8 parts (2 oz. av.); Glycyrrhiza 4 parts (1 oz. av.); Anise 4 parts (1 oz. av.); Cardamom 1 part ($\frac{1}{4}$ oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (25 oz. av.). Mix the rhubarb, glycyrrhiza, anise, and cardamom, and reduce the mixture to a moderately coarse (No. 40) powder; moisten the powder with 15 parts ($3\frac{3}{4}$ oz. av. or $3\frac{1}{2}$ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (25 oz. av. or about 25 fluidounces) of tincture are obtained.

—*U. S.*

This tincture has been in use for a number of years, and was admitted into the Pharmacopœia of 1880. It resembles tincture of rhubarb in appearance, but is one-third weaker in rhubarb, the bitter taste of which is somewhat modified by the other ingredients.

Medical Uses.—From the small proportion of rhubarb in this preparation it may be surmised that it was intended for infantile disorders. But as the aromatic tincture or the aromatic syrup can readily be employed in doses appropriate to such cases, the need of the new official is not apparent. The *dose* may be stated at 2 or 3 fluidrachms (Gm. 8–12).

TINCTURA SABINÆ, Br.—TINCTURE OF SAVIN.*Teinture de sabine, Fr.; Sadebaumtinktur, G.*

Preparation.—Take of Savin Tops, dried and coarsely powdered, $2\frac{1}{2}$ oz. av.; Proof Spirit 1 pint. Prepare the tincture according to the formula given under TINCTURÆ.

—*Br.*

Proof spirit appears to be hardly strong enough for dissolving the volatile oil and resin contained in savin. The tincture has a brown-green color.

Medical Uses.—Tincture of savin may be employed internally in all cases in which that mode of administering savin is appropriate. *Dose*, from 20 minims to a fluidrachm (Gm. 1.30–4).

TINCTURA SANGUINARIÆ, U. S.—TINCTURE OF BLOODROOT.*Teinture de sanguinaire, Fr.; Blutwurzelntinktur, G.*

Preparation.—Sanguinaria in No. 60 powder, 15 parts ($4\frac{1}{2}$ oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 parts (30 oz. av.). Mix alcohol and water in the proportion of 2 parts (20 oz. av. or $23\frac{1}{2}$ fluidounces) of alcohol to 1 part (10 oz. av. or $9\frac{1}{2}$ fluidounces) of water. Moisten the powder with 10 parts (3 oz. av. or $3\frac{1}{4}$ fluidounces) of the mixture, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it until 100 parts (30 oz. av. or about 32 fluidounces) of tincture are obtained.—*U. S.*

In alcoholic and in medicinal strength this tincture corresponds nearly with that of the preceding Pharmacopœia. It has a rich brownish-red color and the bitter and acrid taste of bloodroot.

Medical Uses.—This tincture contains all the virtues of bloodroot. It may be given in *doses* of from 30 to 60 minims (Gm. 2–4) as an “alterative” and expectorant, and as an emetic in doses of from 1 to 4 fluidrachms (Gm. 4–16).

TINCTURA SAPONIS VIRIDIS, U. S.—TINCTURE OF GREEN SOAP.*Spiritus saponis kalinus Hebra, Linimentum saponis viridis.—Teinture de savon vert, Fr.; Hebra's Seifenspiritus, G.*

Preparation.—Green Soap 65 parts ($16\frac{1}{4}$ oz. av.); Oil of Lavender 2 parts ($\frac{1}{2}$ oz. av. or $4\frac{1}{2}$ fluidrachms); Alcohol a sufficient quantity; to make 100 parts (25 oz. av.). Mix the soap and oil of lavender with 33 parts ($8\frac{1}{4}$ oz. av. or $9\frac{1}{2}$ fluidounces) of alcohol, and macerate the mixture until the soap is dissolved; then filter through paper, adding alcohol, through the filter, until 100 parts (25 oz. av.) of tincture are obtained.

—*U. S.*

This preparation was introduced by Prof. Hebra; its name should be changed to Linimentum.

Medical Uses.—This solution of green soap is more convenient than the soap itself, because its smell is not offensive and because it is free from the gritty particles often contained in the soap. It is used chiefly in the treatment of *psoriasis*, *lichen*, *eczema*, and *prurigo*.

TINCTURA SCILLÆ, U. S., Br., P. G.—TINCTURE OF SQUILL.

Teinture de scille, Fr.; *Meerzwiebeltinktur*, G.

Preparation.—Squill, in No. 30 powder, 15 parts ($4\frac{1}{2}$ oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 20 parts (6 oz. av. or $6\frac{1}{2}$ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it moderately in a conical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 30 fluidounces) of tincture are obtained.—U. S.

Squill $2\frac{1}{2}$ oz. av., proof spirit sufficient for 1 pint (Imperial).—Br. Squill 1 part, alcohol (sp. gr. .912, *F. Cod.*) (sp. gr. .894, *P. G.*) 5 parts.

The tincture is of a light-yellow color and has the nauseous bitter taste of squill.

Allied Tincture.—TINCTURA SCILLÆ KALINA. Macerate for a week squill 8 parts and caustic potassa 1 part in alcohol (sp. gr. 0.894) 50 parts; express, and filter. It has a brownish color.—P. G. 1872.

Medical Uses.—Tincture of squill is perhaps better adapted than squill in substance for the treatment of *dropsy*. It is generally associated with other medicines, as in the following efficient formula: ℞. Tincture of digitalis fʒij–fʒiij; tincture of squill fʒss; compound spirit of juniper fʒij; sherry wine fʒx; acetate of potassium ʒj. M.—S. A tablespoonful, largely diluted, three times a day. Tincture of squill is said to have produced diuresis when applied to the skin with friction. The *dose* is from 10 to 20 minims (Gm. 0.60–1.30).

TINCTURA SENEGÆ, Br.—TINCTURE OF SENEGA.

Teinture de polygala de Virginie, Fr.; *Senegatinktur*, G.

Preparation.—Take of Senega-Root, in coarse powder, $2\frac{1}{2}$ oz. av.; Proof Spirit 1 pint (Imperial). Proceed according to the directions given under TINCTURÆ.—Br. Senega 1 part, alcohol (sp. gr. .863) 5 parts.—*F. Cod.*

The tincture has a yellowish-brown color and the acrid taste of senega.

Medical Uses.—This preparation is probably less efficient than the syrup of senega in affections of the air-passages, and than the fluid extract as a stimulant of the uterine functions. The alcohol it contains renders it peculiarly unsuitable in the former, and probably impairs its virtues in the latter case, while it tends to produce a local irritant action upon the stomach. Its *dose* is from 30 minims to 2 fluidrachms (Gm. 2–8).

TINCTURA SENNÆ, Br.—TINCTURE OF SENNA.

Elixir salutis.—*Teinture de séné aromatique*, *Elixir de salut*, Fr.; *Sennatinktur*, G.

Preparation.—Take of Senna, broken small, $2\frac{1}{2}$ oz. av.; Raisins, freed from seeds, 2 ounces; Caraway-Fruit, bruised, Coriander-Fruit, bruised, each $\frac{1}{2}$ ounce; Proof Spirit 1 pint. Prepare 1 pint (Imperial) of tincture according to the formula given under TINCTURÆ.—Br.

Senna 1 part, alcohol (sp. gr. .912) 5 parts.—*F. Cod.*

It is used in preparing *Mistura sennæ comp.*, Br. The formulas of old pharmacopœias directed rhubarb or jalap in addition to the senna.

Medical Uses.—It is convenient as an addition to cathartic infusions, and particularly to the compound infusion of senna, or “black draught,” or along with the tincture of rhubarb in cases that require a stimulating purge, especially in persons of a gouty habit. The *dose* is from 1 to 3 or 4 fluidrachms (Gm. 4–16).

TINCTURA SERPENTARIÆ, U. S., Br.—TINCTURE OF SERPENTARIA.

Teinture de serpentaire, Fr.; *Schlangenwurzeltinktur*, G.

Preparation.—Serpentaria, in No. 40 powder, 10 parts (3 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 10 parts (3 oz. av. or $3\frac{3}{8}$ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it

firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—*U. S.*

Serpentaria 2½ oz. av., proof spirit sufficient to make 1 pint (Imperial).—*Br.*

The tincture has a brownish-yellow color and the camphoraceous odor and taste of the drug.

Medical Uses.—In the low forms of febrile disease for which serpentaria is employed the tincture is the most appropriate form of administering it. It may be associated advantageously in such cases with the compound tincture of cinchona. *Dose*, 1 or 2 fluidrachms (Gm. 4–8).

TINCTURA STRAMONII, *U. S.*, *Br.*—TINCTURE OF STRAMONIUM.

Teinture de semences de stramoine, Fr.; *Stechapfelsamentinktur*, G.

Preparation.—Stramonium-Seed, in No. 40 powder, 10 parts (3 oz. av.); Diluted Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 10 parts (3 oz. av. or 3½ fluidounces) of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it until 100 parts (30 oz. av. or about 31 fluidounces) of tincture are obtained.—*U. S.*

Stramonium-seeds 2½ oz. av., proof spirit sufficient for 1 pint (Imperial).—*Br.*

The tincture has a brownish-yellow color and becomes opalescent with water. The tincture of the first formula is about one-fifth weaker than that of the second formula, and about one-third weaker than that of the *U. S. P.* 1870. *Teinture de stramoine* (*F. Cod.*) is made from stramonium-leaves 1 part and alcohol (sp. gr. .912) 5 parts.

Medical Uses.—Although less frequently used than other preparations of stramonium, the tincture is probably one of the best, whether for internal administration or as a topical anodyne. It would seem appropriate for inhalation, when atomized, in cases of *spasmodic asthma*, and it has been used with marked advantage for the relief of *dysmenorrhœa*. It may also be given internally for the relief of *neuralgia*, and used locally for that affection and for *muscular rheumatism* in anodyne liniments. Even in subacute and chronic *articular rheumatism* it may be employed in the same way with advantage. The average *dose* of the tincture is 15 minims (Gm. 1).

TINCTURA SUMBUL, *Br.*—TINCTURE OF SUMBUL.

Teinture de sumbul, Fr.; *Sumbultinktur*, G.

Preparation.—Sumbul, in No. 30 powder, 10 parts (3 oz. av.); Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 10 parts (3 oz. av. or 3½ fluidounces) of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it until 100 parts (30 oz. av. or about 34 fluidounces) of tincture are obtained.—*U. S.*

Sumbul 2½ oz. av., rectified spirit sufficient for 1 pint (Imperial).—*Br.*

Both these tinctures possess the peculiar musk-like odor in a marked degree. The menstruum of the *Br. P.* 1867 was too weak for exhausting the root; alcohol of about 70 or 75 per cent. appears to be well adapted for this purpose.

Medical Uses.—This tincture probably possesses all the virtues of sumbul. Its *dose* is from 10 to 30 minims (Gm. 0.60–2).

TINCTURA TOLUTANA, *U. S.*, *Br.*—TINCTURE OF TOLU.

Teinture de baume de Tolu, Fr.; *Tolubalsamtinktur*, G.

Preparation.—Balsam of Tolu 10 parts (3 oz. av.); Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Add the balsam of Tolu to 90 parts (27 oz. av. or 31½ fluidounces) of alcohol, and macerate until dissolved; then filter through paper, adding, through the filter, enough alcohol to make the tincture weigh 100 parts (30 oz. av. or about 33 fluidounces).—*U. S.*

Balsam of Tolu 2½ oz. av., rectified spirit sufficient to make 1 pint (Imperial).—*Br.* Balsam of Tolu 1 part, alcohol (sp. gr. .863) 5 parts.—*F. Cod.*

The tincture has a yellowish color, and becomes milky on the addition of water.

Off. Prep.—Trochisci acidi tannici, Troch. morphiae, Troch. morphiae et ipecacuanhæ, Troch. opii, *Br.*

Medical Uses.—This preparation is used for little else than to flavor cough mixtures; it is ineligible even for that purpose, since it is decomposed by water. Its flavor,

however, remains after the removal of its resin, and in this manner the agreeable officinal syrup is formed. *Dose*, 1 or 2 fluidrachms (Gm. 4–8).

TINCTURA VALERIANÆ, U. S., Br., P. G.—TINCTURE OF VALERIAN.

Teinture de valériane, Fr.; *Baldriantinktur*, G.

Preparation.—Valerian, in No. 60 powder, 20 parts (6 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 parts (30 oz. av.). Mix alcohol and water in the proportion of 2 parts (20 oz. av. or 23½ fluidounces) of alcohol to 1 part (10 oz. av. or 9½ fluidounces) of water. Moisten the powder with 15 parts (4½ oz. av. or 5 fluidounces) of the mixture, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it until 100 parts (30 oz. av. or about 32 fluidounces) of tincture are obtained.—*U. S.*

Valerian 2½ oz. av., proof spirit sufficient for 1 pint (Imperial).—*Br.* Valerian 1 part, alcohol (sp. gr. .912, *F. Cod.*) (sp. gr. 894, *P. G.*) 5 parts.

The alcoholic and medicinal strength of the U. S. P has been altered, so that the tincture is practically identical with those of the French and German Pharmacopœias. The tincture is of a brown or reddish-brown color, varying somewhat with the variety of valerian employed, and has the odor and taste of the drug in a marked degree. On the addition of water it becomes opalescent and turbid.

Allied Tincture.—TINCTURA VALERIANÆ ÆTHEREA. Valerian 1 part, spirit of ether 5 parts.—*P. G.* Valerian 2 parts, ether (sp. gr. .724) 7 parts, alcohol 3 parts.—*F. Cod.* It is of a yellow or brownish-yellow color, and becomes opalescent and turbid on the addition of water.

Medical Uses.—The tincture is much less frequently employed than the other preparations of valerian, although in certain cases it is more efficacious—those, namely, in which a prompt and efficient operation is required. Such cases are the *typhoid state* with predominance of ataxic phenomena and *delirium tremens*. On the other hand, in purely nervous disorders, especially of an hysterical kind, it is far less eligible than the infusion, the oil, the ammoniated tincture, or even the fluid extract of valerian. The *dose* is 1 or 2 fluidrachms (Gm. 4–8).

TINCTURA VALERIANÆ AMMONIATA, U. S., Br.—AMMONIATED TINCTURE OF VALERIAN.

Teinture de valériane ammoniacale, Fr.; *Ammoniakalische Baldriantinktur*, G.

Preparation.—Valerian, in No. 60 powder, 20 parts (6 oz. av.); Aromatic Spirit of Ammonia a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the powder with 20 parts (6 oz. av. or 6½ fluidounces) of aromatic spirit of ammonia, and macerate for 24 hours in a closed vessel; then pack it firmly in a cylindrical glass percolator, and gradually pour aromatic spirit of ammonia upon it until 100 parts (30 oz. av. or about 32 fluidounces) of tincture are obtained.—*U. S.*

Valerian 2½ oz. av., aromatic spirit of ammonia sufficient for 1 pint (Imperial).—*Br.*

The tincture is of a brown color, with the odor and taste of valerian and of ammonia.

Medical Uses.—This preparation may be employed in all the disorders in which the simple tincture is eligible, but it is perhaps best adapted to cases of a purely nervous description, in which its use need not be prolonged. It may be given in *doses* of from 30 to 60 or more minims (Gm. 2–4) in sweetened water or mucilage, but never in milk. A non-official preparation, the elixir of valerianate of ammonia, operates in the same manner, but much less energetically. Both are suited to cases of *nervous headache* and of general nervousness with *insomnia* produced by exhaustion of mind or body. *Dose* of the tincture, 1 or 2 fluidrachms (Gm. 4–8).

TINCTURA VANILLÆ, U. S.—TINCTURE OF VANILLA.

Teinture de vanille, Fr.; *Vanilletinktur*, G.

Preparation.—Vanilla, cut into small pieces and bruised, 10 parts (3 oz. av.); Sugar, in coarse powder, 20 parts (6 oz. av.); Alcohol, Water, each a sufficient quantity; to make 100 parts (30 oz. av.). Mix alcohol and water in the proportion of 2 parts (16 oz. av. or 18½ fluidounces) of alcohol to 1 part (8 oz. av. or 7½ fluidounces) of water; macerate the vanilla in 50 parts (15 oz. av. or 16½ fluidounces) of this mixture for 12 hours, then drain off the liquid and set it aside. Transfer the vanilla to a mortar, beat it

with the sugar into a uniform powder, then pack it in a percolator, and pour upon it the reserved liquid; when this has disappeared from the surface gradually pour on menstruum, and continue the percolation until 100 parts (30 oz. av. or about 30 fluidounces) of tincture are obtained.—*U. S.*

Vanilla, cut, 1 part, alcohol (sp. grav. .863) 10 parts.—*F. Cod.*

The first formula agrees in the main with that for *essence* or *fluid extract of vanilla*, given in previous editions of this work; but the strength has been increased about 50 per cent., the commercial essence being usually made from 1 ounce of vanilla to 1 pint of tincture. Maceration of the cut vanilla with a portion of the menstruum previous to beating the former with sugar into powder we regard as an improvement of the manipulation heretofore recommended.

Tincture of vanilla is used only as a flavoring agent.

TINCTURA VERATRI VIRIDIS, *U. S., Br.*—TINCTURE OF VERATRUM VIRIDE.

Tincture of green (American) hellebore, *E.*; *Teinture de vétrate vert*, *Fr.*; *Grün-Nieswurz-tinktur*, *G.*

Preparation.—Veratrum Viride, in No. 60 powder, 50 parts (10 oz. av.); Alcohol a sufficient quantity; to make 100 parts (20 oz. av.). Moisten the powder with 15 parts (3 oz. av. or $3\frac{1}{2}$ fluidounces) of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it until 100 parts (20 oz. av. or about 22 fluidounces) of tincture are obtained.—*U. S.*

Veratrum viride 4 oz. av., rectified spirit sufficient for 1 pint (Imperial).—*Br.*

This tincture is now between 10 and 12 per cent. weaker than that of the *U. S. P.* 1870, but still about two and a half times the strength of that of the *Br. P.* It is of a deep red-brown color, has a bitter and acrid taste, and becomes opalescent and turbid on the addition of water. The present English title is to be preferred to the older one, as not likely to lead to confounding this preparation with the tincture of *Helleborus viridis*, which is employed in some parts of Europe.

Allied Tinctures.—Veratrum viride not being recognized by the French and German Pharmacopœias, these authorities have adopted a tincture from the closely-allied *Veratrum album*:

TINCTURA VERATRI, *P. G.*—Teinture d'hellébore blanc (vétrate blanc), *Fr.*—White veratrum 1 part, alcohol (sp. grav. .863) 5 parts.—*F. Cod.* White veratrum 1 part, alcohol (sp. grav. .894) 10 parts.—*P. G.*

Medical Uses.—The American is more than twice as strong as the British tincture, and may be given to adults in *doses* of 6 or 8 drops (Gm. 0.40–0.50) every three hours, and cautiously increased until nausea is felt or the pulse begins to fall. The dose of the British tincture is from “5 to 20 minims” (Gm. 0.30–1.30). It may be remarked here, as was implied in the account given of green American hellebore itself, that while some of our native physicians exalt this medicine to the rank of a panacea, others condemn its use altogether as scientifically illogical and practically dangerous. Among the latter we desire to be reckoned.

TINCTURA ZINGIBERIS, *U. S., Br., P. G.*—TINCTURE OF GINGER.

Teinture de gingembre, *Fr.*; *Inguwertinktur*, *G.*

Preparation.—Ginger, in No. 40 powder, 20 parts (6 oz. av.); Alcohol a sufficient quantity; to make 100 parts (30 oz. av.). Moisten the ginger with 5 parts ($1\frac{1}{2}$ oz. av. or $1\frac{1}{4}$ fluidounces) of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it until 100 parts (30 oz. av. or about 34 fluidounces) of tincture are obtained.—*U. S.*

Ginger $2\frac{1}{2}$ oz. av., rectified spirit sufficient for 1 pint (Imperial).—*Br.* Ginger 1 part: alcohol (sp. gr. .863, *F. Cod.*) (sp. grav. 0.894, *P. G.*) 5 parts. The tincture is brownish-yellow or reddish, has the aromatic odor and hot taste of ginger, and is rendered milky by water. Diluted alcohol yields a turbid tincture.

Allied Tincture.—TINCTURA ZINGIBERIS FORTIOR, *Br.*—Strong tincture of ginger, *E.*—Take of ginger, in fine powder, 10 ounces, rectified spirit a sufficiency. Pack the ginger tightly in a percolator, and pour over it carefully $\frac{1}{2}$ pint of the spirit. At the expiration of 2 hours add more spirit, and let it percolate slowly until 1 pint (Imperial) of tincture has been collected.—*Br.*

This has about one-half the strength of the fluid extract of ginger.

Off. Prep.—*Pilulæ scammonii comp.*, *Syrup. zingiberis, Br.*; *Trochisci zingiberis, U. S.*

Medical Uses.—These tinctures suffice for nearly all the purposes to which ginger can be applied, either internally or externally, and especially to parts slightly affected with muscular *rheumatism*, and to the abdomen in cases of *nausea* or *colic*, and internally the weaker tincture may be given for flatulent *colic*, *dysmenorrhœa*, etc. The British strong tincture is twice as strong as the American tincture, but neither is as strong as the fluid extract. The latter tincture may be prescribed in *doses* of from 10 to 60 minims (Gm. 0.60–4), the former in the dose of from 5 to 30 minims (Gm. 0.30–2).

TORMENTILLA.—TORMENTIL.

Rhizoma tormentillæ, P. G.—*Tormentille*, Fr.; *Tormentillwurzel*, G.

The rhizome of *Potentilla Tormentilla*, Schrank (*P. sylvestris*, *Necker*, *P. erecta*, *Karsten*, *Tormentilla erecta*, *Linne*, *T. officinalis*, *Curtis*). *Bentley and Trimen, Med. Plants*, 101.

Nat. Ord.—*Rosaceæ*, *Rosææ*.

Origin.—The tormentil-plant grows in open woodlands and grassy places throughout Europe and Northern Asia, and flowers from May to August. It resembles our cinquefoil, but has numerous ascending or weak stems, with trifoliate and frequently opposite, sessile upper leaves, and long-peduncled yellow tetramerous flowers.

Description.—Tormentil attains a length of 3 inches (75 Mm.), but as usually seen is about 2 inches (5 Cm.) long, about $\frac{1}{2}$ inch (12 Mm.) thick, irregularly cylindrical or obconical, occasionally branched, and has the surface covered with numerous roundish protuberances, and between these with depressions from which remnants of thin wiry rootlets project. The rhizome has externally a dark-grayish, red-brown color, is hard, breaks with a nearly smooth somewhat resinous fracture, is internally light or deeper brownish-red, and consists of a thin bark, of a large pith, and of one or two circles of small yellowish wood-wedges separated by broad medullary rays. In the fresh state tormentil has a faint rose-like odor, but after drying, by which process it diminishes nearly 70 per cent in weight, it is inodorous and has a strongly astringent taste.

Constituents.—Meissner (1822) obtained from tormentil 17.5 per cent. of tannin, 18 per cent. of *tormentil-red*, soluble in alcohol and ether, not in water, and smaller quantities of wax, resin, mucilage, etc. Scheele has proved the presence of oxalate of calcium. Bowman (1869) estimated the amount of tannin with gelatin at between 24 and 30 per cent. Rembold (1867) corroborated the previous observations of Grischow and Baldman concerning the presence of a small quantity of *ellagic acid*; found the *tormentil-red* to be probably identical with the allied red compound of rhatany and horse-chestnut, since with potassium hydrate it yields protocatechuic acid and phloroglucin; established the presence of notable quantities of *kinovic acid*, $C_{24}H_{38}O_4$, and obtained the *tormentil-tannic acid* of the composition $C_{26}H_{22}O_{11}$. The tannin is precipitated by gelatin, gives with ferric chloride a blue-green reaction, and yields tormentil-red, but no sugar, on being boiled with dilute sulphuric acid.

Medical Action and Uses.—This drug is almost obsolete even in Europe, and is hardly known in this country. It is a pure and powerful astringent, which can be used, like tannic acid and the plants that contain it, for constricting relaxed tissues, diminishing *fluxes*, arresting passive *hæmorrhages*, etc. The *dose* of the powder is 5 grains (Gm. 0.30) or more. A decoction or infusion is prepared with from 1 to 4 drachms of it in half a pint (Gm. 4–16 in Gm. 250) of water, which may be taken in tablespoonful doses or applied topically.

FIG. 298.

Tormentilla: root and transverse section.

TRAGACANTHA, U. S., Br., P. G.—TRAGACANTH.

Gummi tragacantha.—*Gomme adragante*, Fr.; *Traganth*, G.

The gummy exudation from *Astragalus gummifer*, *Labillardiere*, and from other species of *Astragalus*. Bentley and Trimen, *Med. Plants*, 73.

Nat. Ord.—Leguminosæ, Papilionacæe.

Origin.—The genus *Astragalus* comprises numerous herbaceous, suffruticose, and shrubby species, and is characterized by its flowers having ten stamens, nine of which are united into a bundle, and by having the lower suture of their legumes inflexed so as to make the fruit apparently two-celled. The subgenus *Tragacantha* has the stipules united with the permanent petioles, which become thorny. According to Boissier and Haussknecht, the principal species yielding tragacanth are *Astragalus adscendens*, *Bois. et Haussk.*, *A. brachycalyx*, *Fischer*, *A. microcephalus*, *Willdnor*, *A. pycnocladus*, *Bois. et Haussk.*, *A. stromatodes*, *Bunge*, *A. kurdicus*, *Bois.*, *A. cylleneus*, *Bois. et Heldreich* (probably a variety of *A. Parnassi*, *Boissier*); also, *A. verus*, *Olivier*, and *A. creticus*, *Lamarck*. All are low shrubs, indigenous to a portion of the territory lying between Eastern Persia and Greece.

The secretion of tragacanth is due to a transformation of the cell-walls, with their inner layers, of the pith and medullary rays contained in the stem and older branches, as was first observed by Hugo von Mohl (1857), whose observations were corroborated by Wigand (1861). The altered tissue is confined in the plant between the wood-wedges with considerable tension, and oozes out with some force on breaking a branch or making an incision.

Collection.—Tragacanth exudes spontaneously either from fissures or from punctures and longitudinal incisions made into the stem and older branches. From such incisions flake tragacanth is obtained, while the spontaneously exuding gum often forms irregularly globular or somewhat conical pieces. The rapidity with which the gum exudes chiefly determines the shape in which it ultimately hardens, and the time which elapses before it is sufficiently hard for collection influences the color of the product, which is white if congealed rapidly, and more or less yellowish and brown if hardened slowly. Tragacanth enters commerce from the ports of Asia Minor and from the Persian Gulf.

Properties.—Tragacanth consists of different layers, either laid upon one another and spirally twisted, or confluent into tear-like masses, or extended into curved, narrow, or broad bands, varying in width between $\frac{1}{4}$ inch and 1 inch (6 and 25 Mm.), and sometimes 4 or 5 inches (10–13 Cm.) long. These bands are rarely made up of a single layer, but usually are marked with several parallel ridges, indicating the various strata, which are united into broader and thicker laminae. This form of tragacanth is known as *flake tragacanth* or *leaf gum*, and is the more valuable the whiter and more translucent it is. Smyrna tragacanth is mostly in rather broad and thick flakes, which are yellowish or of a brownish tint, and often prominently ridged. Thin, ribbon-like, and white flakes are produced in Kurdistan and Persia, but are sometimes distinguished in commerce as Syrian tragacanth. Another variety is *vermiform tragacanth*, also called *vermicelli*. It consists of very narrow, variously coiled, and contorted string-like pieces, the different coils of which are most frequently confluent. *Common tragacanth*, or *sorts*, in Europe known as *traganton*, is the product obtained by spontaneous exudation, forming subglobular, conical, or variously shaped tear-like pieces, with the surface rounded and more or less irregular, and usually of a brownish or brown color, and rather waxy in appearance; but it shows the stratification described above, and, like the white and thin bands, encloses starch.

Tragacanth is hard, tough, difficult to powder, inodorous, and tasteless, insoluble in alcohol and ether, and forms with 50 parts of water a thick, jelly-like mucilage. When diffused in a much larger quantity of water it forms a ropy liquid which may be passed through a filter, leaving behind an insoluble residue, which in contact with iodine acquires a blue color from the presence of starch. The mucilage acquires a yellow color on the addition of caustic soda, and the solution of tragacanth yields clear mixtures with borax, ferric chloride, and sodium silicate, is precipitated by alcohol, thickened by cold lead acetate and subacetate, and precipitated by these salts on heating (Flückiger).

Composition.—The soluble gum is not identical with arabin, though its solution is precipitated by alcohol and ammonium oxalate. The insoluble gum is known as *bassorin*, *tragacanthin*, *adraganthin*. It is soluble in hydrochloric acid and in ammonia, and is stated to have the composition $C_{12}H_{20}O_{10}$. According to Giraud (1876), tragacanth consists

essentially of *pectose* or a closely-allied principle, which on being digested with water is gradually converted into a soluble compound, *pectin*, which is precipitated by alcohol. He regards it as very improbable that tragacanth should originate from a transformation of cellulose, since this body is ordinarily converted into dextrin and sugar, which compounds are not met with in tragacanth. According to this author, the average composition of tragacanth is 20 per cent. water, 60 per cent. pectin compound, 8 to 10 per cent. soluble gum, 3 per cent. cellulose, 2 or 3 per cent. starch, 3 per cent. of mineral constituents, and a trace of nitrogenous matter. By drying, tragacanth loses about 15 per cent. of moisture; the ash contains over half its weight of calcium carbonate.

Allied Gums.—CHERRY GUM. The different species of cherry and plum trees frequently yield gummy exudations which harden to irregular nodulous masses, are of a more or less brown color, translucent, and dissolve imperfectly in water. According to Guérin, the insoluble portion of this gum is not identical with bassorin.

BASSORA or KUTERA GUM is a Persian product of unknown origin, and is met with in yellowish or brownish, semi-transparent, and tasteless masses, which swell considerably with water. It is used in Smyrna for adulterating the cheaper varieties of tragacanth, and is then usually broken into smaller pieces of about the same size as the tragacanth. Such broken pieces are angular, and are said to be sometimes artificially whitened with white lead. This fraud may be readily detected by treating the gum with cold dilute nitric acid, when the presence of lead in the solution may be established without difficulty.

CASHEW GUM, *Gomme acajou*, is an exudation of *Anacardium occidentale* (see page 201), is brown-yellow, translucent, somewhat iridescent, and partly soluble in water. (See also HOG GUM, page 10.)

Other Species of Astragalus.—A. BAETICUS, *Linné*. An herbaceous annual of the basin of the Mediterranean. Its brownish-yellow, angular, subcubical seeds have been used as a substitute for coffee; they were examined by Trommsdorff (1824).

A. EXSCAPUS, *Linné*. This perennial is indigenous to the mountainous parts of Southern and Central Europe. Its root is mucilaginous, somewhat astringent and bitter, and was formerly used as a diuretic. Examined by Fleuret (1833), no peculiar active principle was found.

A. GLYCYPHYLLOS, *Linné*. The leaves and seeds of this perennial, indigenous to Europe and Northern Asia, have an unpleasant sweet taste and are used as diuretics.

A. CROTALARIE, *Gray*. This is a Californian plant, known as *loco-weed* and *rattle-weed*, and is reported to be poisonous to horses and cattle.

A. MOLLISSIMUS, *Torrey*. It is indigenous to North America west of the Mississippi from Nebraska to Western Texas, and is said to be poisonous to horses; the leaflets are densely covered with a glossy, soft, white or yellowish pubescence.

Off. Prep.—Confectio opii, *Br.*; Mucilago tragacanthæ, *U. S., Br.*; Pulv. opii comp., Pulv. tragacanthæ comp., *Br.*; Trochisci, *U. S.*

Medical Action and Uses.—Tragacanth is demulcent and nutritious. It was apparently unknown to the Greek physicians until the fourth or fifth century, and was then used to allay cough and hoarseness and promote expectoration, and, in a word, for all the affections in which gum-arabic has been employed. Its difficult solubility renders it less eligible than the latter gum in most instances. On the other hand, the greater tenaciousness of its mucilage fits it to be a better protective in some local affections, such as burns.

A. mollissimus has been studied by Dr. Isaac Ott, who summarizes its effects as follows: It lessens the irritability of the motor nerves and of the sensory ganglia of the central nervous system; has a spinal tetanic action; reduces the action of, and then arrests, the heart; salivates; ultimately it diminishes arterial tension, and dilates the pupil (*Phila. Med. Times* xii. 892).

TRILLIUM.—BETHROOT.

Birthroot, Wakerobin.—*Trillium*, *Fr., G.*

The rhizome of *Trillium erectum*, *Linné*.

Nat. Ord.—Liliaceæ.

Origin.—Bethroot is generally stated to be obtained from *Trillium pendulum*, which is now regarded as a white flowering variety of *Tr. erectum*, but the drug as met with in the market is evidently derived from different plants, and it is not unlikely that in different localities bethroot is collected from such species of *Trillium* as may be most abundant. All the species have a simple stem, mostly about a foot (30 Cm.) high, bearing at its apex a single hexandrous flower, and beneath it a whorl of three leaves, which are reticulate-palmately veined and usually broadly ovate or rhomboid in shape. The fruit is a triangular-ovate, three-celled, and many-seeded dark purple or red berry. The dif-

ferent species grow in moist thickets and shady woods in various parts of the United States and Canada. Two of the species have the dark-purple flower sessile between the leaves—namely, *Tr. sessile*, *Linné*, with erect petals and sessile leaves, and *Tr. recurvatum*, *Beck*, with recurved petals and stalked leaves. Two species have white flowers on erect peduncles and petiolate leaves—namely, *Tr. nivale*, *Riddell*, with the leaves and petals obtuse, and *Tr. erythrocarpum*, *Michx.*, with pointed leaves and petals, and the latter striped with purple near the base. *Tr. cernuum*, *Linné*, and *Tr. stylosum*, *Nuttall*, have white or rose-colored flowers on peduncles which are deflexed under the leaves, the last-named species being distinguished by the partly-united styles. *Tr. erectum*, *Linné*, bears a nodding and finally deflexed flower, with dark-purple spreading petals, or in the variety album (*Tr. pendulum*, *Muhlenberg*) with greenish-white or yellowish petals. The variety *declinatum* has a horizontal peduncle and white or pink-colored petals. *Tr. grandiflorum*, *Salisbury*, has a large white or rose-colored suberect flower.

Description.—Bethroot is a subglobular, oblong, or nearly obconical and oblique rhizome, which is truncate at the lower end and terminates above with a short tuft of sheathing leaf-bases. The rhizome is 1 or 1½ inches (25–38 Mm.) long, ½ to ¾ inch (12–18 Mm.) in diameter, slightly flattened, finely but distinctly annulate, and, particularly in the upper portion, beset with circular rows of straw-colored or pale-brownish rootlets or with the short remnants of the same. Bethroot is externally of a yellowish orange-brown color, internally whitish or more frequently yellowish or light-brown, and upon transverse section is seen to be composed of rather spongy parenchyma and of small scattered fibro-vascular bundles, which are circular, elongated, or irregularly curved, and more numerous toward the circumference than near the centre. It is inodorous or nearly so, and has a sweetish, astringent, afterward bitter and acrid taste.

Constituents.—On moistening a section of bethroot with solution of iodine the tissue assumes a uniform blue color, with the exception of the wood-bundles, proving the presence of starch in the parenchyma. From an investigation by Prof. E. S. Wayne (1856), it appears that on evaporating the tincture and diluting with water fatty and resinous matter, and perhaps a little volatile oil, are separated, and that from the aqueous liquid tannin and coloring matter are precipitated by acetate and subacetate of lead, while the acrid principle remains in solution. On removing the excess of lead by sulphuric acid and filtering, the acrid principle, or probably a decomposition-product of it, is deposited as a gelatinous mass, soluble in alcohol, but insoluble in water, and producing with it on agitation a permanent foam. The principle deserves further investigation.

Medical Action and Uses.—This is one of the plants used as a medicine by the American aborigines. Its acrid principle causes it to irritate the mouth and throat when chewed, and increase the flow of saliva. It is reputed to be astringent, tonic, and alterative, and to have a special action upon the uterine system, controlling *menorrhagia* and quickening the uterine contractions during *parturition*. For the latter reason it received the name of “birthwort.” In large doses the root is alleged to be emetic, and the bruised herb has been applied with supposed advantage to unhealthy *ulcers* and to *tumors*. *Trillium erectum* appears to be the most active species. The *dose* of its dried and powdered root is stated at 1 drachm (Gm. 4).

TRIMETHYLAMINA.—TRIMETHYLAMINE.

Triméthylamine, Fr.; *Trimethylamin*, G.

Formula $(CH_3)_3N$. Molecular weight 59.

Origin and Preparation.—This compound, frequently incorrectly called *propylamine*, with which it is isomeric, has been obtained from ergot (*secaline*), from the leaves of *Beta vulgaris* and *Chenopodium Vulvaria*, from the flowers of *Arnica montana*, *Pyrus communis*, *Sorbus aucuparia*, and *Cratægus oxyacantha*, and from cod-liver oil, bone oil, and guano. It is also produced on heating codeine with potassa, but may be economically obtained from herring-pickle, which contains this alkaloid in considerable quantity and owes to it its peculiar odor. A mixture of herring-pickle and lime is subjected to distillation, the alkaline distillate is neutralized with hydrochloric acid and evaporated, and the saline residue is treated with absolute alcohol, which leaves ammonium chloride undissolved. The alcoholic solution is evaporated, the residue redissolved in a little water, and again carefully distilled with lime. If the vapors are first passed through an empty bottle before they are condensed by means of ice or conducted into water, several less volatile alkaloids are separated in the bottle. Large quantities of trimethylamine are now obtained from the residues left in the preparation of sugar from beets.

Properties.—In its pure state trimethylamine is a colorless, thin, and strongly alkaline liquid having a strong ammoniacal odor modified by the peculiar odor of herring-pickle, and boiling at 9.8° C. (49.6° F.). At ordinary temperatures it is a colorless, inflammable gas. It is readily soluble in water and alcohol, and an aqueous solution of it has been sold as *propylamine*. The chloroplatinate of trimethylamine is soluble in alcohol and water, crystallizes in well-defined orange-colored octahedrons, and contains 37.21 per cent. of platinum. More characteristic, particularly in the presence of methylamine and allied bases, is the double salt with gold, which is very sparingly soluble in cold water and has the composition $N(CH_3)_3HCl.AuCl_3$ (Hesse, 1857, 1883).

HYDROCHLORATE OF TRIMETHYLAMINE is obtained on neutralizing the alkaloid with hydrochloric acid and evaporating. It crystallizes in white or colorless prisms, is nearly inodorous, has a saline pungent taste, is very deliquescent on exposure, and dissolves freely in water and alcohol.

Allied Compounds.—**AMYLAMINA**, $C_5H_{11}H_2N$, is a colorless liquid, having a penetrating ammoniacal odor, and the density 0.7503 at 18° C., and boiling at 95° C. (203° F.). The hydrochlorate crystallizes in octahedrons, is freely soluble in water and alcohol, and is insoluble in ether.

PROPYLAMINA, $C_3H_7H_2N$, is a colorless, strongly refracting, inflammable liquid of an ammoniacal odor, boiling at 50° C. (122° F.), and yielding with platinic chloride a double salt, which crystallizes in orange-yellow clinorhombic plates.

METHYLAMINA, $(CH_3)_2HN$, and **DIMETHYLAMINA**, $(CH_3)_2HN$, are colorless inflammable gases of an ammoniacal odor, very soluble in water, and condensing to colorless liquids, the former at -18° C. (0.4° F.), the latter below 8° C. (46.4° F.).

NEURINA, **CHOLINA**, $C_5H_{15}NO_2$, is present in bile to a small extent, and is obtained by boiling bile with caustic baryta, and in a similar manner from brain, yolk of egg (see *VITELLUS*), and mustard-seed (*sinkaline*, see p. 1373); it has also been prepared synthetically. It is a colorless, syrupy, non-volatile liquid of a strongly alkaline reaction, very hygroscopic, combining readily with carbonic acid gas, and soluble in alcohol or water in all proportions; on heating it gives off trimethylamine, and on boiling its aqueous solution the same alkaloid is given off and ethylene-glycol produced. On treating its hydriodate with silver oxide, the anhydrous base, $C_5H_{13}NO$, is separated. By careful oxidation *betaine*, $C_5H_{11}NO_2$ (see p. 939), is produced. Neurine has been used in diphtheritis, and has also been called *amanitine* (see p. 716), which has the same composition, but on oxidation yields *muscarine*.

Physiological Action.—*On Animals:* When from 20 to 30 grains of trimethylamine were injected under a rabbit's skin in the course of an hour, there occurred trembling with convulsive succussion, agitation, increased excito-motor action, with hyperæsthesia and quickened cardiac and respiratory movements. These phenomena were followed by a period of depression or collapse and a degree of motor paresis, with death by asphyxia. In frogs the same phenomena essentially were produced, and the heart-beats fell from 64 or 68 at the commencement of the experiment to 34, 20, and 12, and finally were suspended. Doses of from 30 to 50 grains introduced into a dog's stomach excited immediate vomiting. Smaller and repeated doses occasioned anxiety, distress, immobility, general muscular tremor, accelerated action of the heart, distaste for food, and marked emaciation; bloody urine was voided at the end of six days, charged with biliary and coloring matters, and there were increased reflex excitability and hyperæsthesia. In the rabbits killed by this substance discoloration, gangrene, and emphysema were found at the point of hypodermic injection. The lungs were congested and spots of subpleural ecchymosis existed. The heart contained large black clots in both cavities. The kidneys were congested, and the bladder was filled with non-albuminous urine of an ammoniacal odor. Husemann, however, in his experiments on rabbits, observed neither bloody urine nor congestion of the lungs or kidneys (*Arch. f. exper. Pathol. u. Pharm.*, vi. 55). Other experimenters (Dujardin-Beaumetz) state that as much as 75 grains of muriate of trimethylamine may be administered subcutaneously to rabbits without occasioning toxic phenomena, and that when they perished their death seemed always to be due to the caustic action of the salt upon the tissues. This observer attributes the depression and collapse of the animals to the pain produced by this caustic action. But his judgment seems untenable. The mode of death in animals killed by this substance, given hypodermically or by the stomach, and especially the persistence of the heart's beats after the suspension of respiration, appear to prove that it does not act directly as a heart-poison, but indirectly, through the spinal marrow, first upon the respiratory muscles, and then upon the heart. In many experiments the excitability of the heart persisted for quite ten minutes after general death.

On Man: Applied to the sound skin, trimethylamine is negative in its action unless friction is employed, in which case it causes redness very much as ammonia does. Upon

the mucous membrane it acts as a strong irritant, causing a lively sense of burning, with redness, and if allowed to continue its action it produces superficial ulceration. Its taste is ammoniacal and saline, and if taken in a large dose and undiluted it occasions a burning sensation in the throat, œsophagus, and stomach. Propylamine and muriate of trimethylamine agree in their effects; 30 or 40 grains of the former or 10 grains of the latter will reduce the pulse about ten beats in the minute, and under the influence of the muriate the temperature may fall 1° or 2° F. In febrile rheumatism the decline of the pulse-rate and temperature is more decided. But the medicine causes neither diaphoresis, diuresis, colic, nor diarrhœa.

Medical Uses.—The disease in connection with which trimethylamine was first brought into notice, and the only one in which its importance as a medicine was recognized, is *articular rheumatism*. It does not appear what motives first led to its use in the treatment of this affection by Awenarius of St. Petersburg, who between 1854 and 1856 treated by its means more than two hundred and fifty rheumatic patients, and affirmed that it dissipated the pain of the acute disease from one day to another. Isolated statements attributing to it a similar efficacy were made in France previous to 1864; but in 1870, Lagrange confirmed them, and in 1873, Dujardin-Beaumetz gave the history of seven cases of acute articular rheumatism which were cured in a very short time by trimethylamine. The improvement in general was rapid, and sometimes great relief was experienced within twelve hours, the pain first and then the swelling subsiding, as well as the fever. Further experience led him to conclude that of all the remedies hitherto used in the treatment of acute articular rheumatism, muriate of trimethylamine appeared to be the most efficient. A number of physicians in France have sustained this conclusion by their own experience; a few have published a similar judgment in England, and also in Germany. The less favorable accounts of some others are attributed to their having made use of ill-prepared and inert preparations of the medicine or of those which did not contain a due proportion of the active ingredient. As will be observed, this history of the virtues of trimethylamine in rheumatism has a striking analogy with that of salicylic acid and its salts in the same disease; the same mode of action is attributed to the two medicines, and the same extraordinary curative powers are ascribed to both. The newer remedy has, however, so entirely supplanted the older that hardly any trace of the latter can be found in medical literature since 1879.

Weiss has reported that this medicine is very efficient in the treatment of *chorea*, moderating the spasmodic movements greatly, even when it did not suspend them, when it was given to the extent of 15 or 20 grains (Gm. 1–1.30) a day.

The *dose* of trimethylamine is from 2 to 6 minims (Gm. 0.10–0.40) every three or four hours. Its extremely offensive taste and smell render necessary its administration in syrup flavored with mint, or anise, or some other aromatic water. To obviate this difficulty, the substitution of the chloride of trimethylamine, which has no smell and only a faint taste, has been proposed. Dr. J. L. Tyson has reported favorably of its use in doses of 2 grains every two hours (*Philad. Med. Times*, ix, 374). It is generally given in doses of 2 or 3 grains (Gm. 0.10–0.20), dissolved in a syrup and repeated at similar intervals, so that not less than 15 grains (Gm. 1) shall be taken during the day.

TRIOSTEUM.—FEVER-ROOT.

Feverwort, Horse-gentian, Bastard ipœcac, Tinker's weed, E.; Racine de trioste, Fr.; Dreisteinwurzel, G.

The root of *Triosteum perfoliatum*, Linné.

Nat. Ord.—Caprifoliaceæ.

Origin.—This perennial herb is indigenous to the United States, grows in woodlands, and flowers in June. The stem is from 2 to 4 feet (0.6–1.2 M.) high, soft-hairy, and has opposite spatulate-ovate and entire leaves, which are about 4 inches (10 Cm.) long, abruptly narrowed below and connate at the base. The flowers are in axillary clusters, and have a five-lobed brown-purple corolla, about $\frac{1}{2}$ inch (12 Mm.) long. The ripe fruit is orange-colored, drupaceous, and contains three hard nutlets. All parts of the plant have a bitter taste, but only the rhizome and roots are employed. The more slender and rougher *Tr. angustifolium*, Linné, which grows chiefly in the Western and Southern United States, is said to have similar properties.

Description.—The rhizome is horizontal, from 6 to 12 inches (15–30 Cm.) long, knotty-cylindrical, about $\frac{3}{4}$ inch (18 Mm.) thick, somewhat branched, and on the upper side bears numerous cup-shaped scars of the over-ground stems about $\frac{1}{4}$ inch (6 Mm.)

in diameter. The numerous spreading rootlets are inserted mainly on the lower side of the rhizome, and are at their base $\frac{1}{4}$ to $\frac{3}{8}$ inch (6–9 Mm.) thick, and 5 to 10 inches (12–25 Cm.) long. Both the rhizome and roots are slightly wrinkled longitudinally, externally of a yellowish-brown color, internally white, and contain a hard, slightly bitter wood, with delicate medullary rays. The bark of the rhizome is thin, that of the roots rather thick, and has a bitter somewhat nauseous taste. Fresh fever-root has a slight disagreeable odor, which is dissipated on drying.

Constituents.—On moistening a transverse section of the roots with solution of iodine a deep-blue color is imparted to the medullary rays and the cambium-layer, but the bark acquires only a slight blue tinge. Fever-root has not been subjected to analysis; its bitter principle is dissolved both by water and alcohol.

Medical Uses.—A decoction of this plant is said to have been used by some of the American aborigines in the treatment of *fevers* and *female obstructions*. The fresh root, in the dose of from 20 to 30 grains (Gm. 1.30–2), and the extract in the dose of 10 or 15 grains (Gm. 0.60–1), purge actively after the manner of jalap. The bark of the root is said to be emetic.

TRITICUM, U. S.—TRITICUM.

Rhizoma graminis, P. G.; *Radix graminis*.—*Couch-grass*, *Quick-grass*, *Quickens*, *Quitch*, E.; *Chiendent officinal*, *Petit chiendent*, Fr.; *Queckenwurz*, *Grasswurz*, G.

The rhizome of *Triticum* (*Agropyrum*, *Beauvais*) repens, *Linné*, collected in the spring and deprived of the rootlets.

Nat. Ord.—Graminacæ.

Origin.—Couch-grass is a troublesome perennial weed growing along roadsides and in cultivated grounds throughout the northern hemisphere. The plant has a long, jointed, whitish rhizome, with a tuft of fibrous rootlets at each joint. The culm is about 2 or sometimes 4 feet (0.6–1.2 M.) high, and has compressed spikes 3 or 4 inches (7–10 Cm.) long, and four- to eight-flowered spikelets. The florets are variable, mostly awnless, and either pointed or rather obtuse.

Description.—Couch-grass root is met with in the market cut into short sections, about $\frac{1}{2}$ to $\frac{2}{3}$ inch (5–10 Mm.) in length, about $\frac{1}{12}$ inch (2 Mm.) in diameter, of a straw-

FIG. 299.

Triticum repens: rhizome; transverse section, magnified 3 diam.

FIG. 300.

Section through portion of rhizome, magnified 65 diam.

yellow color, smooth, hollow in the centre, inodorous, and of a sweet taste. The transverse section shows the central cavity surrounded by a narrow layer of delicate parenchyma, projecting somewhat into the equally narrow circle of fibro-vascular bundles, which is separated by the nucleus-sheath from the broad outer layer of parenchyma containing about six or eight isolated, distant fibro-vascular bundles in a loose circle.

Constituents.—The latest analysis of couch-grass root is by Ludwig and H. Müller (1872, 1873), who obtained from it malates, a nitrogenous principle which is readily darkened by heat, fruit-sugar (2.4 to 3.3 per cent.), levulose, and a right-rotating sugar which is not identical with cane-sugar. A peculiar gum-like principle, *triticin*, was isolated, which resembles inulin in its optical behavior, and, like this, may be converted into levulose. It is obtained by exhausting the rhizome with water, neutralizing with baryta, concentrating, precipitating with subacetate of lead, removing the excess of lead, treating with animal charcoal, neutralizing the filtrate, again concentrating, and precipitating by alcohol (Reidemeister 1880). *Triticin* is amorphous and transparent in thin layers or forms a white powder; it is inodorous, tasteless, very hygroscopic, in damp air deliques-

cent, insoluble in ether and absolute alcohol, and is oxidized by nitric acid to oxalic acid. Mannit, which was stated by Berzelius (1837) and Völker (1846) to be present in the rhizome, has not been obtained by later investigators; but the extract of couch-grass root may contain calcium lactate, and possibly also mannit, as products resulting from fermentation. Couch-grass root yields about 4.5 per cent. of ash, which is rich in silica.

Allied Drugs.—SORGHUM-FRUIT is $\frac{1}{8}$ or $\frac{1}{4}$ inch (3–4 Mm.) long, nearly as wide, broadly oval, somewhat flattened, brownish-yellow, and somewhat granular externally, or covered with the glossy dark-purple paleæ; internally white and mealy; inodorous and of a farinaceous and sweetish taste.

Off. Prep.—Extractum tritici fluidum, *U. S.*

Medical Action and Uses.—Couch-grass was employed by the ancients as a vulnerary and for the relief of dysury. They also believed that it removed stone, or at least gravel, from the bladder. In modern times it has been very generally regarded as emollient, antiphlogistic, and diuretic. Its infusion is a common medicinal drink in European hospitals and private life, and is regarded as adapted to relieve thirst, allay fever, and promote urination. It was formerly employed as a popular diet-drink to “purify the blood” in the spring season, and doubtless assisted in purging, through the kidneys, the accumulated organic detritus of a long winter. It was also thought to be very efficient in relieving congestions of the liver and portal circulation with *jaundice* arising under analogous circumstances, and in a less degree chronic *bronchitis*, *skin diseases*, *gout*, etc. It was even alleged to be capable of curing gastric cancer and removing biliary calculi. In truth, it possesses no special medicinal virtues beyond being, when given in infusion, an agreeable drink, which, owing to the sugar it contains, tends to increase the urinary secretion, and thereby palliate irritations of the *urinary passages*. It is best administered in a decoction prepared with from 2 to 4 ounces of the plant in 2 pints of water (Gm. 64–128 in Gm. 1000), and reduced one-half by boiling. The official fluid extract may be used for the same purposes if largely diluted.

Sorghum vulgare or broom-corn seeds are said to have been in common use as a remedy for disorders of the bladder by the plantation negroes of Maryland and Virginia. They made a decoction by boiling 2 ounces of the seed in a quart of water until reduced to a pint. It has been found useful as a palliative in several cases of *cystitis* by Dr. Garnett (*Amer. Jour. of Med. Sci.*, July, 1881, p. 165).

TRITURATIONES, *U. S.*—TRITURATIONS.

Triturations, Fr.; *Triturationen*, G.

This term has been used in homœopathic pharmacy in the same sense in which it has been adopted by the *U. S. Pharmacopœia*—namely, for powders, prepared by trituration, of a medicinal substance with a definite quantity of milk-sugar. In homœopathy this is done with the view of developing the medicinal power, and two proportions are used, termed the centesimal and the decimal scales; 1 part of the substance being triturated with 99 parts or with 9 parts of the milk-sugar, gradually added.

Preparation.—The directions for preparing these powders are very similar to those followed in homœopathic dispensing, except that the length of time for mixing and triturating has been omitted.

“Triturations are to be prepared by the following formula: Take of the substance 10 parts, sugar of milk, in moderately fine powder, 90 parts; to make 100 parts. Weigh the substance and sugar of milk separately; then place the substance, previously reduced, if necessary, to a moderately fine powder, in a mortar; add about an equal bulk of sugar of milk, mix well by means of a spatula, and triturate them thoroughly together. Add fresh portions of the sugar of milk from time to time until the whole is added, and continue the trituration until the substance is intimately mixed with the sugar of milk, and finely comminuted.”—*U. S.*

Medical Uses.—The utility of this new title is open to very grave doubts on moral as well as therapeutical grounds. It encourages the prevalent habit, as erroneous scientifically as it is practically misleading, that the doses of medicines are fixed quantities. Sugar of milk is undoubtedly susceptible of minuter division by trituration than cane-sugar, but its use is a practical detail that may very well be left to the physician and the pharmacist, and modified according to circumstances.

TRITURATIO ELATERINI, U. S.—TRITURATION OF ELATERIN.

Trituration d'élaterine, Fr.; Elaterintrituration, G.

Preparation.—Elaterin 10 parts, Sugar of Milk 90 parts; to make 100 parts. Mix them thoroughly by trituration.—*U. S.*

Medical Uses.—The average dose of elaterin being $\frac{1}{16}$ grain (Gm. 0.004), and the proportion of the drug in the trituration being one-tenth, it follows that the dose of the latter should be about $\frac{1}{8}$ grain (Gm. 0.05).

TROCHISCI, U. S., Br., P. G.—TROCHES.

Tabellæ, F. Cod.—Lozenges, E.; Tablettes, Pastilles, F.; Pastillen, Zeltchen, G.

Troches are mixtures of medicinal substances with sugar or extract of liquorice, formed by the aid of mucilage into stiff, pasty masses, and divided into flat circular, oblong, rectangular, or stellate pieces, usually weighing about 10 or 20 grains. A cylindrical shape has been adopted for a few of the officinal lozenges. The French Codex makes a distinction between tablettes and pastilles, and applies the former term to the preparations just defined, and restricts the term *pastilles* to the sugar drops described below.

Preparation.—The dry ingredients are separately reduced to fine powders and thoroughly mixed in a mortar or by sifting. Volatile oils, tinctures, and similar liquids should now be intimately incorporated with the powder, and the whole beaten into a rather firm mass by the addition of mucilage of tragacanth or of acacia. The mass is then rolled out into sheets of suitable thickness and cut into the requisite number of pieces by a punch. A hard and smooth board or a polished marble slab, dusted over with finely-powdered sugar, is well adapted for this purpose; and in order to keep the mass at a somewhat elevated temperature while being rolled out the roller is sometimes made of iron or glass and hollow in the interior, so that it may be filled with water of any desired temperature. When lozenges are ordered on extemporaneous prescriptions, the mass is usually rolled out into a square, rectangular, or rhombic cake, and then divided by means of a ruler and knife into the requisite number of pieces, all having the same size and shape. After lozenges have been cut they are spread out on a sieve or other surface and exposed to a current of warm air until they are sufficiently dry.

The amount of powdered tragacanth necessary for imparting the requisite adhesiveness varies with the nature of the ingredients; 1 part of it is sufficient for 100 parts, and even more, of sugar and similar powders if, after the addition of water, the mass is well beaten. A much larger proportion of tragacanth renders the lozenges, after some time, very hard and slowly soluble. If mucilage of acacia is employed instead of tragacanth, the lozenges become somewhat translucent, and a similar effect is produced by employing the white of eggs as the adhesive material. Some manufacturers employ a machine with movable dies for cutting lozenges of any desired shape, and for stamping them at the same time with the name of the principal ingredient. A simple instrument for cutting lozenges with a tubular punch has been described by A. D. Marcy in *New Remedies*, 1882, p. 34. Lozenge-boards, adjustable for different sizes, are described by F. L. Slocum and F. E. Harrison in *Amer. Jour. Pharmacy*, 1879, p. 589, and 1880, p. 254.

If the lozenges are to be made of a cylindrical shape, the mass is rolled out into thin cylinders, in a manner similar to that of making pills, and then cut into shorter pieces having the requisite weight. The mass should be sufficiently firm not to flatten on drying, and the rolling-board, instead of being dusted with sugar, is greased with a little olive oil, to prevent the mass from adhering to it. (For a description and sketch of an apparatus by F. C. Hill, suitable for making such lozenges, see *Amer. Jour. Phar.*, 1874, p. 402.)

The general directions of the French Codex for the preparation of tablettes agree with

Board, Roller, and Punch for making Lozenges.

the description given above. But for some years past *compressed tablets* have been in use, prepared in a manner similar to that in which compressed pills are made (see p. 1166); and this form has been adopted by the German Pharmacopœia, which gives the following general directions: "For preparing *sugar pastilles*, the whole amount of the medicinal substance is intimately mixed with sufficient powdered sugar to make each lozenge weigh 1 Gm.; alcohol (sp. gr. .994) is now carefully added to produce a damp powder, which by compression will form a coherent mass; from this powder the requisite number of lozenges are made. For *chocolate pastilles* a mass is made by melting together, with the aid of a steam-bath, equal weights of cacao and sugar, and a sufficient weight of medicinal substance is added, so as to form lozenges weighing 1 Gm.; the somewhat cooled mass is then divided into the requisite number of lozenges."

The French Codex likewise directs the *tablettes* to weigh 1 Gm., and permits some kinds to be variously flavored, for which purpose to every 1000 Gm. of mass may be added 1 Gm. of volatile oil of anise, lemon, or peppermint or 10 Gm. of tincture of vanilla; and in case the flavor of rose or orange-flower be desired, the distilled aromatic water is used in the place of water for preparing the mucilage employed in rendering the mass plastic.

PASTILLI (ROTULÆ) SACCHARI.—Sugar lozenges, Sugar drops, *E.*; Pastilles, Orbicules, *Fr.*; Zuckerplätzchen, *G.*—This form of lozenges is usually made by the confectioner, and the medication merely is left to the pharmacist. The lozenges are prepared by mixing, in a pan having a suitable lip, some granulated sugar with a sufficient quantity of water to form a pasty mixture; this is heated carefully to prevent empyreuma, until it begins to boil. An additional quantity of sugar is then stirred in to give the requisite consistence; 100 parts of sugar require about 12 to 15 parts of water. The semi-liquid mass is now poured out upon cold, polished sheet iron in such a manner that each drop is kept separate, when, on touching the iron plate, it will congeal into a flattish hemispherical body. The peppermint drops of the French Codex are made in this manner, $\frac{1}{2}$ per cent. of oil of peppermint being incorporated with the sugar and $12\frac{1}{2}$ per cent. of water; this mixture is heated in small portions and dropped in the manner stated. *Chocolate drops* are made by a similar process. The term *trochisques*, formerly used in France for such lozenges, is now usually applied to the little cones obtained in drying elutriated powders (see p. 517).

ROTULÆ MENTHÆ PIPERITÆ. *P. G.*—Peppermint drops, *E.*; Pastilles de menthe à la goutte, *Fr.*; Pfefferminzkuchen, *G.*—Dissolve 1 part of oil of peppermint in 2 parts of alcohol; add the solution to 200 parts of sugar drops in a bottle, and well agitate, so as to impregnate them uniformly with the liquid; afterward expose to the air for a few minutes, and when the alcohol has evaporated keep in a stoppered bottle. By substituting other volatile oils for the oil of peppermint, lozenges of any desired flavor may be obtained.

Most of the lozenges of the British Pharmacopœia vary but slightly from 1 Gm. (15.43 grains) in weight, but the majority of the troches of the U. S. Pharmacopœia weigh between $10\frac{1}{2}$ and $12\frac{1}{2}$ grains, or between .68 and .80 Gm., while troches of cubeb weigh $6\frac{3}{4}$ grains (.44 Gm.), and troches of potassium chlorate 25 grains (1.63 Gm.).

In addition to the troches described below, the following have been admitted by the French Codex, of which we give the title and the weight of medicinal ingredient in each: *Tablettes de baume de Tolu*, .05 Gm.; *T. de borate de soude*, .10 Gm.; *T. de calomel*, .05 Gm.; *T. de charbon*, .50 Gm.; *T. de gomme*, .01 Gm.; *T. de guimauve*, .01 Gm.; *T. de kermès*, .01 Gm.; *T. de lichen* (made with one-third saccharure, p. 419); *T. de manne*, .20 Gm.; and *T. de soufre*, .10 Gm.

TROCHISCI ACIDI TANNICI, U. S., Br.—TROCHES OF TANNIC ACID.

Tablettes (Pastilles) de tannin, Fr.; *Tanninpastillen, G.*

Preparation.—Tannic Acid 100 grains (6.50 Gm.); Sugar, in fine powder, 1000 grains (65 Gm.); Tragacanth, in fine powder, 25 grains (1.60 Gm.); Orange-Flower Water a sufficient quantity; to make 100 troches. Rub the powders together until they are thoroughly mixed; then with orange-flower water form a mass, to be divided into 100 troches.—*U. S.*

Tannic acid 360 grains; tincture of Tolu $\frac{1}{2}$ fluidounce; refined sugar, in powder, 25 oz. av.; gum-acacia, in powder, 1 oz. av.; mucilage of gum-acacia 2 fluidounces; distilled water 1 fluidounce; prepare 720 lozenges.—*Br.*

TROCHISCI ACIDI BENZOICI, Br., are made like the preceding from 360 grains of benzoic acid, but omitting tincture of tolu.

Medical Uses.—Tannic acid troches are suitable in relaxed states of the mucous membrane of the mouth, throat, and larynx to allay *cough* produced by irritation of these parts. They may also be used in mild cases of *diarrhœa* after a preliminary evacuation of the bowels.

TROCHISCI AMMONII CHLORIDI, U. S.—TROCHES OF CHLORIDE OF AMMONIUM.

Tablettes (Pastilles) de sel ammoniac, Fr.; Salmiakpastillen, G.

Preparation.—Chloride of Ammonium, in fine powder, 200 grains (13 Gm.); Sugar, in fine powder, 1000 grains (65 Gm.); Tragacanth, in fine powder, 25 grains (1.60 Gm.); Syrup of Tolu a sufficient quantity; to make 100 troches. Rub the powders together until they are thoroughly mixed; then with syrup of Tolu form a mass, to be divided into 100 troches.—*U. S.*

Medical Uses.—These lozenges may be used to palliate subacute and chronic inflammations of the *throat* and *air-passages*, but they are less efficient than the inhalations recommended elsewhere. Their objectionable taste would have been palliated and their curative action improved by substituting extract of liquorice for a portion of the sugar they contain.

TROCHISCI BISMUTHI, Br.—BISMUTH LOZENGES.

Tabellæ cum subnitrate bismuthico, F. Cod.—Tablettes (Pastilles) de sous-nitrate de bismuth, Fr.; Wismuthpastillen, G.

Preparation.—Take of Subnitrate of Bismuth 1440 grains; Carbonate of Magnesia 4 oz. av.; Precipitated Carbonate of Lime 6 ounces; Refined Sugar 29 ounces; Gum-Acacia, in powder, 1 ounce; Mucilage of Gum-Acacia 2 fluidounces; Rose-Water a sufficiency. Mix the dry ingredients, then add the mucilage, and form the whole into a proper mass with rose-water. Divide the mass into 720 lozenges, and dry these in a hot-air chamber with a moderate heat. Each lozenge contains 2 grains of subnitrate of bismuth.—*Br.*

The corresponding lozenges of the French Codex contain 0.10 Gm. (1.5 grain) of the subnitrate, but no magnesia or calcium carbonate.

Medical Uses.—This form of administering bismuth is very unprofitable, since bismuth does not act except mechanically and by diffusion.

TROCHISCI CATECHU, U. S., Br.—TROCHES OF CATECHU.

Tabellæ cum catechu, F. Cod.—Catechu lozenges, E.; Tablettes (Pastilles) de cachou, Fr.; Katechupastillen, G.

Preparation.—Catechu, in fine powder, 100 grains (6.50 Gm.); Sugar, in fine powder, 1000 grains (65 Gm.); Tragacanth, in fine powder, 25 grains (1.60 Gm.); Orange-Flower Water a sufficient quantity; to make 100 troches. Rub the powders together until they are thoroughly mixed; then with orange-flower water form a mass, to be divided into 100 troches.—*U. S.*

Pale catechu, in powder, 720 grains; refined sugar, in powder, 25 oz. av.; acacia, in powder, 1 oz. av.; mucilage of gum-acacia 2 fluidounces; distilled water a sufficiency; prepare 720 lozenges.—*Br.* Each lozenge contains 1 grain, *U. S., Br.* (0.10 Gm. = 1.5 grain *F. Cod.*) of catechu.

Medical Uses.—These troches, each containing 1 grain of catechu, are serviceable in the cases mentioned under troches of tannic acid. They are generally employed to obviate the *hoarseness* or huskiness of the voice due to prolonged speaking or to slight *pharyngeal* or *laryngeal catarrh*.

TROCHISCI CRETÆ, U. S.—TROCHES OF CHALK.

Tablettes (Pastilles) de craie lavée, Fr.; Kreidepastillen, G.

Preparation.—Prepared Chalk 400 grains (26 Gm.); Acacia, in fine powder, 100 grains (6.50 Gm.); Nutmeg, in fine powder, 15 grains (1 Gm.); Sugar, in fine powder, 600 grains (39 Gm.); to make 100 troches. Rub them together until they are thoroughly mixed; then with water form a mass, to be divided into 100 troches.—*U. S.*

The nutmeg, freshly grated, should be rubbed into a uniform powder with a portion of the sugar. Each lozenge contains 4 grains (.26 Gm.) of prepared chalk.

Medical Uses.—Troches of chalk may be used to correct *acidity* of the stomach and a slight tendency to *diarrhœa*.

TROCHISCI CUBEÆ, U. S.—TROCHES OF CUBEÆ.

Pastilles de cubèbe, Fr.; *Kubebenpastillen*, G.

Preparation.—Oleoresin of Cubeæ 50 grains (3.25 Gm.); Oil of Sassafras 15 grains (1 Gm.); Extract of Glycyrrhiza, in fine powder, 400 grains (26 Gm.); Acacia, in fine powder, 200 grains (13 Gm.); Syrup of Tolu a sufficient quantity; to make 100 troches. Rub the powders together until they are thoroughly mixed; then add the oleoresin and oil and incorporate them with the mixture. Lastly, with syrup of Tolu form a mass, to be divided into 100 troches.—U. S.

This is a modification of the formula for *Spitta's lozenges*, from which it differs essentially in the substitution of oleoresin for powdered cubebs. The lozenges are usually made of a cylindrical shape, and each contains $\frac{1}{2}$ grain of oleoresin of cubeb.

Medical Uses.—These troches are chiefly used in cases of subacute and chronic inflammation of the *pharynx* and *larynx*, especially when those parts are covered with viscid mucus.

TROCHISCI FERRI, U. S.—TROCHES OF IRON.

Trochisci ferri subcarbonatis, U. S. 1870; *Tablettes (Pastilles) de l'hydrate de fer*, Fr.: *Ferrihydrat-Pastillen*, G.

Preparation.—Hydrated Oxide of Iron, dried at a temperature not exceeding 80° C. (176° F.), 500 grains (32.50 Gm.); Vanilla, cut into slices, 10 grains (0.65 Gm.); Sugar, in fine powder, 1500 grains (97.50 Gm.); Mucilage of Tragacanth a sufficient quantity; to make 100 troches. Rub the vanilla first with a portion of the sugar to a uniform powder, and afterward with the oxide of iron and the remainder of the sugar, until they are thoroughly mixed. Then with mucilage of tragacanth form a mass, to be divided into 100 troches.—U. S.

Each lozenge contains 5 grains of ferric hydrate. The French Codex recognizes three lozenges made with soluble salts of iron—namely, *Tablettes de lactate de fer*, T. de citrate de fer ammoniacal, and T. de tartrate de fer ammoniacal.—*F. Cod.* These are flavored with vanilla, and each lozenge contains .05 Gm. ($\frac{1}{4}$ grain) of the salt.

Medical Uses.—Hydrated oxide of iron in troches is only a little less objectionable than the reduced iron troches of the British Pharmacopœia. Both deserve to be classed among pharmaceutical and medical superfluities. We may repeat concerning troches of iron what was said of troches of the subcarbonate of iron in a former edition of this work: they are convenient for administering to “refractory children, who may be tempted by their agreeable flavor to take them.” Each troche contains 5 grains (Gm. 0.30) of hydrated oxide of iron.

TROCHISCI FERRI REDACTI, Br.—REDUCED IRON LOZENGES.

Tablettes (Pastilles) de fer, *Tablettes chalybées*, Fr.; *Eisenpastillen*, G.

Preparation.—Take of Reduced Iron 720 grains; Refined Sugar, in powder, 25 oz. av.; Gum-Acacia, in powder, 1 oz. av.; Mucilage of Gum-Acacia, 2 fluidounces; Distilled Water 1 fluidounce or a sufficiency. Mix the iron, sugar, and gum, and add the mucilage and water to form a proper mass. Divide into 720 lozenges, and dry these in a hot-air chamber with a moderate heat. Each lozenge contains 1 grain of reduced iron.—*Br.*

Medical Uses.—It is not easy to discern the merits of this preparation. Reduced iron can be serviceable only when it is acidulated by the gastric acids, and that action is better secured by administering it in powder.

TROCHISCI GLYCYRRHIZÆ ET OPII, U. S.—TROCHES OF GLYCYRRHIZA (LIQUORICE) AND OPIUM.

Trochisci opii, Br.—*Opium lozenges*, E.; *Pastilles d'opium*, P. de réglisse opiacées, Fr.; *Opiumpastillen*, G.

Preparation.—Extract of Glycyrrhiza, in fine powder, 200 grains (13 Gm.); Extract of Opium, in fine powder, 5 grains (0.32 Gm.); Acacia, in fine powder, 200 grains (13

Gm.): Sugar, in fine powder, 300 grains (19.50 Gm.); Oil of Anise 3 grains (0.20 Gm.); to make 100 troches. Rub the powders together until they are thoroughly mixed; then add the oil of anise, and incorporate it with the mixture. Lastly, with water form a mass, to be divided into 100 troches.—*U. S.*

Extract of opium 72 grains, tincture of Tolu $\frac{1}{2}$ fluidounce; refined sugar, in powder, 16 oz. av.; gum-acacia, in powder, 2 oz. av.; extract of liquorice 6 oz. av.; distilled water a sufficiency; prepare 720 lozenges.—*Br.*

The lozenge of the first formula (*U. S.*) contains $\frac{1}{30}$, and that of the second formula (*Br.*) $\frac{1}{10}$, grain of extract of opium. The lozenges of the United States Pharmacopœia are much used under the name of *Wistar's cough lozenges*, and are prepared of a cylindrical shape. Formerly, they were made with opium instead of the extract of opium, and some manufacturers substitute for opium an equivalent quantity of morphine. Lozenges of the same shape and composition, but with the omission of opium or morphine, have been introduced as *liquorice lozenges*, and are similar to the *Trochisci bechici nigri*, which are still used to some extent in Europe, and usually contain a small quantity of orris-root and balsam of Tolu.

Medical Uses.—This popular medicine is well adapted for use in *bronchitis* and *laryngitis* attended with harassing cough, but without marked febrile reaction. Its efficiency is greatly increased in the more acute forms of the affections mentioned by the addition of a minute proportion of tartar emetic, not exceeding the fortieth of a grain, or of half a grain of ipecacuanha, to each troche. On an average, one troche may be taken every three hours, but in general it is better to use the third of a troche every hour.

TROCHISCI IPECACUANHÆ, *U. S.*, *Br.*—TROCHES OF IPECAC.

Tabellæ cum ipecacuanha, *F. Cod.*—*Ipecacuanha lozenges*, *E.*; *Tablettes (Pastilles) d'ipecacuanha*, *Fr.*; *Brechwurzelpastillen*, *G.*

Preparation.—Ipecac., in fine powder, 25 grains (1.60 Gm.); Tragacanth, in fine powder, 25 grains (1.60 Gm.); Sugar, in fine powder, 1000 grains (65 Gm.); Syrup of Orange a sufficient quantity; to make 100 troches. Rub the powders together until they are thoroughly mixed; then with syrup of orange form a mass, to be divided into 100 troches.—*U. S.*

Ipecacuanha, in powder, 180 grains; refined sugar, in powder, 25 oz. av.; gum-acacia, in powder, 1 oz. av.; mucilage of gum-acacia 2 fluidounces; distilled water 1 fluidounce or a sufficiency; prepare 720 lozenges.—*Br.*

Each lozenge contains $\frac{1}{4}$ grain (.016 Gm.) *U. S.*, *Br.*, .01 Gm. ($\frac{1}{4}$ grain) *F. Cod.*, of ipecacuanha.

Medical Uses.—Ipecacuanha troches are useful in *laryngeal* and *bronchial inflammation* before secretion has been established. One troche, containing a quarter of a grain of ipecacuanha, may be taken every half hour until the dryness of the air-passages abates or the stomach begins to be nauseated. On the other hand, they are often very serviceable in *humid asthma*, or that asthmatic affection which is met with in cases of pulmonary emphysema complicated with obstructive disease of the heart, especially as they may conveniently be carried about by the patient and used in anticipation of a paroxysm.

TROCHISCI KRAMERIÆ, *U. S.*—TROCHES OF KRAMERIA.

Tablettes (Pastilles) de ratanhia, *Fr.*; *Ratanhapastillen*, *G.*

Preparation.—Extract of Krameria 100 grains (6.50 Gm.); Sugar, in fine powder, 1000 grains (65 Gm.); Tragacanth, in fine powder, 25 grains (1.60 Gm.); Orange-Flower Water a sufficient quantity; to make 100 troches. Rub the powders together until they are thoroughly mixed; then with orange-flower water form a mass, to be divided into 100 troches.—*U. S.*

Medical Uses.—Krameria troches may be used for the same purposes as tannic acid or catechu troches—*i. e.* for constringing the mucous membrane of the mouth, fauces, larynx, and digestive canal.

TROCHISCI MAGNESIÆ, *U. S.*—TROCHES OF MAGNESIA.

Tablettes (Pastilles) absorbantes, *Fr.*; *Magnesiapastillen*, *G.*

Preparation.—Magnesia 300 grains (19.50 Gm.); Nutmeg, in fine powder, 15

grains (1 Gm.); Sugar, in fine powder, 900 grains (58.50 Gm.); Mucilage of Tragacanth a sufficient quantity; to make 100 troches. Rub the magnesia and the powder together until they are thoroughly mixed; then with mucilage of tragacanth form a mass, to be divided into 100 troches.—*U. S.*

The freshly-grated nutmeg should be rubbed into a uniform powder with a portion of the sugar.

TABELLÆ CUM CARBONATE MAGNESICO.—Tablettes (Pastilles) de magnésie, *F. Cod.*—contain .20 Gm. (3 grains) of magnesium carbonate.

Medical Uses.—The proportion of magnesia in these troches is too small, and that of sugar too large, to render them efficient antacid medicines, which they are generally supposed to be. Each troche, weighing 12 grains, contains about 3 grains (Gm. 0.20) of magnesia.

TROCHISCI MENTHÆ PIPERITÆ, *U. S.*—TROCHES OF PEPPERMINT.

Tablette cum oleo volatile menthæ piperitæ, *F. Cod.*—*Tablettes de menthe*, *Pastilles de menthe anglaises*, *Fr.*; *Pfefferminzpastillen*, *G.*

Preparation.—Oil of Peppermint 15 grains (1 Gm.); Sugar, in fine powder, 1200 grains (78 Gm.); Mucilage of Tragacanth a sufficient quantity; to make 100 troches. Rub the oil of peppermint and the sugar together until they are thoroughly mixed; then with mucilage of tragacanth form a mass, to be divided into 100 troches.—*U. S.*

These lozenges, made according to the French Codex, contain 1 per cent. of the volatile oil. (See also PASTILLI SACCHARI and ROTULÆ MENTHÆ PIPERITÆ, under the general heading TROCHISCI.)

Medical Uses.—Peppermint troches are employed to relieve *flatulence* and *colic* and to prevent *sea-sickness* and other forms of *nausea*. They are apt to excite gastric pain when too freely used.

TROCHISCI MORPHINÆ, *Br.*—MORPHINE LOZENGES.

Pastilles de morphine, *Fr.*; *Morphinpastillen*, *G.*

Preparation.—Take of Hydrochlorate of Morphine 20 grains; Tincture of Tolu $\frac{1}{2}$ fluidounce; Refined Sugar, in powder, 24 oz. av.; Gum-Acacia, in powder, 1 oz. av.; Mucilage of Gum-Acacia a sufficiency; Distilled Water $\frac{1}{2}$ fluidounce. Dissolve the hydrochlorate of morphia in the water; add this solution to the tincture of Tolu, previously mixed with 2 ounces of the mucilage; then add the gum and sugar, previously mixed, and more mucilage if necessary to form a proper mass. Divide into 720 lozenges, and dry these in a hot-air chamber with a moderate heat.—*Br.*

Medical Uses.—Each of these lozenges contains about $\frac{1}{36}$ grain (Gm. 0.0018) of hydrochlorate of morphine. They are chiefly used to allay *laryngeal* and *bronchial irritation*.

TROCHISCI MORPHINÆ ET IPECACUANHÆ, *U. S.*, *Br.*—TROCHES OF MORPHINE AND IPECAC.

Morphia and ipecacuanha lozenges, *E.*; *Tablettes (Pastilles) de morphine et d'ipecacuanha*, *Fr.*; *Morphinpastillen mit Brechwurzel*, *G.*

Preparation.—Sulphate of Morphine 5 grains (0.32 Gm.); Ipecac, in fine powder, 16 grains (1 Gm.); Sugar, in fine powder, 2000 grains (130 Gm.); Oil of Gaultheria 2 grains (0.13 Gm.); Mucilage of Tragacanth a sufficient quantity; to make 200 troches. Rub the powders together until they are thoroughly mixed; then add the oil of gaultheria, and incorporate it with the mixture. Lastly, with mucilage of tragacanth form a mass, to be divided into 200 troches.—*U. S.*

Hydrochlorate of morphia 20 grains; ipecacuanha, in fine powder, 60 grains; tincture of Tolu $\frac{1}{2}$ fluidounce; refined sugar, in powder, 24 oz. av.; gum-acacia, in powder, 1 oz. av.; mucilage of gum-acacia a sufficiency; distilled water $\frac{1}{2}$ fluidounce; prepare 720 lozenges.—*Br.*

Medical Uses.—Each of these troches contains about $\frac{1}{36}$ grain of sulphate or hydrochlorate of morphine (Gm. 0.0016) and $\frac{1}{12}$ grain (Gm. 0.005) of ipecacuanha. They allay *cough* and promote expectoration.

TROCHISCI POTASSII CHLORATIS, *U. S.*, *Br.*—TROCHES OF CHLORATE OF POTASSIUM.

Tabellæ cum chlorate potassico, F. Cod.—*Tablettes (Pastilles) de chlorate de potasse*, Fr.; *Kaliumchlorat-Pastillen*, G.

Preparation.—Chlorate of Potassium, in fine powder, 500 grains (32.50 Gm.); Sugar, in fine powder, 1900 grains (124 Gm.); Tragacanth, in fine powder, 100 grains (6.50 Gm.); Spirit of Lemon 10 grains (0.65 Gm.). Mix the sugar with the tragacanth and the spirit of lemon by trituration in a mortar; then transfer the mixture to a sheet of paper, and by means of a bone spatula mix with it the chlorate of potassium, being careful to avoid trituration and pressure, to prevent the mixture from igniting or exploding. Lastly, with water form a mass, to be divided into 100 troches.—*U. S.*

Take of chlorate of potash, in powder, 3600 grains; refined sugar, in powder, 25 ounces; gum-acacia, in powder, 1 ounce; mucilage of gum-acacia 2 fluidounces; distilled water 1 fluidounce or a sufficiency. Mix the powders, and add the mucilage and water to form a proper mass. Divide into 720 lozenges, and dry these in a hot-air chamber with a moderate heat.—*Br.*

By both the above formulas lozenges are obtained containing 5 grains of potassium chlorate; those of the French Codex contain only 0.10 Gm. (1.5 grains) of the same salt.

Medical Uses.—Chlorate of potassium troches may be used in the treatment of *aphthæ* and other forms of *ulcer* of the mouth and throat, but they are much less efficient than solutions of the chlorate.

TROCHISCI SODII BICARBONATIS, *U. S.*, *Br.*—TROCHES OF BICARBONATE OF SODIUM.

Tabellæ cum bicarbonate sodico, F. Cod.—*Bicarbonate of soda lozenges*, E.; *Tablettes (Pastilles) de bicarbonate de soude*, P. de Vichy, P. digestives, Fr.; *Natronpastillen*, G.

Preparation.—Bicarbonate of Sodium 300 grains (19.50 Gm.); Sugar, in fine powder, 900 grains (58.50 Gm.); Nutmeg, in fine powder, 15 grains (1 Gm.); Mucilage of Tragacanth a sufficient quantity; to make 100 troches. Rub the bicarbonate of sodium with the powders until they are thoroughly mixed; then with mucilage of tragacanth form a mass, to be divided into 100 troches.—*U. S.*

Bicarbonate of soda 3600 grains; refined sugar, in powder, 25 oz. av.; gum-acacia, in powder, 1 oz. av.; mucilage of gum-acacia 2 fluidounces; distilled water 1 fluidounce; prepare 720 lozenges.—*Br.*

The freshly-grated nutmeg should be rubbed with a portion of the sugar to a uniform powder, and afterward thoroughly mixed with the remaining powders. In France these lozenges are variously flavored, either with the volatile oil of anise, lemon, or peppermint, with the distilled water of orange-flowers or rose, or with tincture of vanilla. As directed by the different pharmacopœias, the lozenges contain 5 grains (.33 Gm.) *Br.*, 3 grains (.20 Gm.) *U. S.*, and 0.025 Gm. ($\frac{3}{8}$ grain) *F. Cod.*, of bicarbonate of sodium.

Medical Uses.—Troches of bicarbonate of sodium are convenient and useful in cases of habitual *acidity* of the stomach. The utility of the nutmeg they contain is not apparent.

TROCHISCI SODII SANTONINATIS, *U. S.*—TROCHES OF SANTONINATE OF SODIUM.

Tablettes (Pastilles) de santonate de soude, Fr.; *Santoninnatronpastillen*, G.

Preparation.—Santoninate of Sodium, in fine powder, 100 grains (6.50 Gm.); Sugar, in fine powder, 2000 grains (130 Gm.); Tragacanth, in fine powder, 50 grains (3.25 Gm.); Orange-Flower Water a sufficient quantity; to make 100 troches. Rub the powders together until they are thoroughly mixed; then with orange-flower water form a mass, to be divided into 100 troches. Troches of santoninate of sodium should be kept in dark, amber-colored vials.—*U. S.*

These troches have been introduced, on account of the greater solubility of the sodium compound, to take the place of santonin lozenges (see page 1339).

Medical Uses.—Each troche contains about 1 grain (Gm. 0.06) of santoninate of sodium. One may be given every three or four hours until three or four are taken or until the sight begins to be affected, when a purgative dose of castor oil should be admin-

istered. They are employed chiefly for the destruction of *lumbrioid* worms and rectal *ascarides*. It is almost certain that these troches will be found less efficient than the *santonin* troches they have displaced. Their very solubility must tend to prevent their reaching the intestinal parasites they are used to expel.

TROCHISCI ZINGIBERIS, U. S.—TROCHES OF GINGER.

Tablettes (Pastilles) de gingembre, Fr.; Ingwerpastillen, G.

Preparation.—Tincture of Ginger 200 grains (13 Gm.); Tragacanth, in fine powder, 50 grains (3.25 Gm.); Sugar, in fine powder, 2000 grains (130 Gm.); Syrup of Ginger a sufficient quantity; to make 100 troches. Mix the tincture of ginger with the sugar, and, having exposed the mixture to the air until dry, reduce it to a fine powder; to this add the tragacanth and mix thoroughly. Lastly, with syrup of ginger form a mass, to be divided into 100 troches.—*U. S.*

Medical Uses.—Troches of ginger are used to relieve flatulent *colic* and quicken laborious digestion.

TUSSILAGO.—COLTSFOOT.

Folia farfarae, s. tussilaginis, P. G.—Tussilage, Pas d'âne, Fr.; Hufplattig, Rosshuf, G.

Tussilago Farfara, Linné.

Nat. Ord.—Compositæ, Eupatoriæ.

Origin and Description.—Coltsfoot is a perennial herb which is indigenous to Europe and Northern Asia, has been naturalized in the United States from New England to Pennsylvania, and grows in damp clayey soil and along ditches and brooks. All parts of the plant have been used, but the leaves and flower-heads have been generally employed, and the former have been admitted into the German, the latter into the French, Pharmacopœia. The *rhizome* is creeping, 12 to 18 inches (30–45 Cm.) long, branching, about $\frac{1}{4}$ inch (3 Mm.) thick, with joints about 2 inches (5 Cm.) long, radiating on the nodes, and of a grayish-white or pale-brownish color. It is fragile when dry, has a thick whitish bark, yellowish porous wood-wedges, and a prominent pith, is inodorous, and has a mucilaginous, bitterish, and astringent taste. The *leaves* appear after the flowers, and are radical, long-petiolate, about 4 inches (10 Cm.) long and broad, roundish heart-shaped, angular-toothed, dark-green and smooth above, and white tomentose beneath. They are rather fleshy while fresh, and fragile after drying. The *flower-heads* are smaller than those of dandelion, make their appearance in early spring upon scaly scapes, and have a cylindrical involucre of lance-linear scales in a single row, numerous yellow narrowly-ligulate pistillate ray-florets in several rows, and about twenty tubular staminate disk-florets. The pappus is long, silky-hairy, and white. The dried flowers and leaves are inodorous and have a mucilaginous, bitterish, and somewhat astringent taste.

The rhizome of *Asarum canadense* is known in some parts of the United States as *coltsfoot-root*.

Constituents.—All parts of coltsfoot contain *mucilage*, a *bitter principle* which has not been isolated, and *tannin*, producing a dark-green precipitate with ferric salts.

Medical Action and Uses.—Coltsfoot was anciently renowned in pulmonary affections, and for their relief the smoke of its burning root was inhaled through a funnel; even in modern times it was smoked in pipes for the same purpose by the peasantry of Sweden and Germany. It is demulcent and tonic through its mucilaginous and bitter constituents, and has been compared in its action to Iceland moss. It has been widely used in the treatment of chronic *bronchitis* and for various *scrofulous* affections, both internally and locally. It may be administered in decoction or infusion made with an ounce of the dried leaves and flowers to a pint (Gm. 32 to Gm. 500) of water. The expressed juice is also employed.

ULMUS, U. S.—ELM (SLIPPERY ELM).

Ulm cortex, Cortex ulmi interior.—*Elm-bark, E.; Orme fauve, Orme champêtre, Fr.; Ulmenrinde, Rüsterrinde, G.*

The inner bark of *Ulmus fulva, Michx.* (*U. S. F. Cod.*), of *Ulmus campestris, Linné (F. Cod.)*. Bentley and Trimen, *Med. Plants*, 232, 233.

Nat. Ord.—Urticacææ, Ulmææ.

Origin.—The elms are trees with alternate, oblique, and slightly heart-shaped, serrate, and straight-veined leaves, and with lateral clusters of small polygamous flowers, having a bell-shaped four- to nine-lobed perianth, the same number of stamens, and two nearly sessile styles. The fruit is a one-celled and one-seeded samara, surrounded with a membranous wing, which is notched or cleft at the apex. The American official elm, known as *slippery elm*, *red elm*, or *moose elm*, is a small or medium-sized tree, which is usually about 30, and occasionally 60, feet (9–18 M.) high, with a diameter of 1 or 2 feet (30–60 Cm.), and with a reddish wood. The leaves are 4 to 8 inches (10–20 Cm.) long, elliptic-oblong, pointed and very rough above; the flowers are reddish pubescent, precede the leaves, and have the perianth six- to nine-cleft; the samara is orbicular and not ciliate. The tree grows in woods and rich soil from Canada westward to Lake Superior and Nebraska, and southward to near the Gulf of Mexico, but is most abundant in the Western States. The *white elm*, *Ulmus americana*, *Linnaë*, is taller, 60 to 80 feet (18–24 M.) high, bears an oval, on the margin densely ciliate samara, and is a favorite shade tree in New England.

Ulmus alata, *Michaux*, the winged elm, grows in the Southern United States, where it is known as *wahoo* (see also p. 596). The wood is fine-grained and heavy, and the bark, which on the branches has prominent corky wings, is used for making ropes.

The European official elm is probably a native of Western Asia and Eastern Europe, but now is naturalized or cultivated throughout the greater portion of Asia, Europe, and Northern Africa. It has likewise been introduced in some parts of New England. Its leaves are only about $2\frac{1}{2}$ inches (6 Cm.) long, oval or obovate, and acute or somewhat pointed; the flowers are mostly pentamerous, and the samara is roundish-obovate, smooth, and has the seed placed near the apical notch. The European *black elm*, *Ulmus effusa*,

Willdenow, which has larger ovate or elliptical leaves and roundish-elliptic ciliate fruits, likewise furnishes some elm-bark.

Description.—SLIPPERY-ELM BARK is met with in commerce in flat pieces, consisting of the liber only, the corky layer being removed before drying, and usually several feet long and 4 or 6 inches (10–15 Cm.) broad. It is about $\frac{1}{4}$ inch (3 Mm.) thick, is externally of a very light-cinnamon color or pale brownish-white, smooth, occasionally with small fragments of the corky layer adhering, and upon the inner surface grayish-white, finely ridged longitudinally, and usually more or less woolly from some detached bast-fibres. The bark breaks, or rather tears, readily in a longitudinal direction, the fragments adhering together with the wavy bast-fibres. It breaks with some difficulty in a transverse direction with a fibrous and mealy fracture, and when cut transversely the bast-fibres are seen arranged in tangential rows, imbedded in a loose parenchyma, and dissected by numerous fine medullary rays, giving to the transverse section a delicately checkered appearance. Slippery-elm bark has a slight but distinct odor, resembling that of fenugreek, and a mucilaginous, insipid taste. It is also met with as a coarse fibrous and as a somewhat fine and uniform powder, both having a light fawn-color.

EUROPEAN ELM BARK. It resembles the preceding, but is usually rather thinner, upon both surfaces of a cinnamon color, nearly inodorous, and of a mucilaginous, bitterish, and astringent taste.

Constituents.—Both barks contain a considerable amount of mucilage, which, as obtained from the European elm, according to Braconnot (1846), resembles the mucilage of flaxseed. The mucilage of slippery-elm bark is precipitated by acetate of lead, but alcohol separates from its solution a gelatinous liquid; starch is present in small grains. European elm bark contains a small quantity of a bitter principle which has not been isolated, and a little tannin, which is precipitated by gelatin and the salts of most metals, gives a dingy-green precipitate with ferric chloride, reduces gold and silver salts, is a glucoside, and on fusion with potassa yields pyrocatechin and acetic and butyric acids (Johansen, 1875). Starch is usually not present in the bast-layer of this bark.

Medical Action and Uses.—Slippery-elm bark is highly demulcent, and in some degree nutritious. It is grateful to the taste, and does not readily disorder the stomach. Like the inner bark of the European elm (*U. Campestris*), which is slightly astringent, it has been used with alleged advantage in chronic *cutaneous eruptions*, including some of syphilitic origin. It is also asserted to be a remedy for *tape-worm*. It is, however, chiefly employed in medicine to produce a mucilage which is official. The fibrous bark, disintegrated so as to form a mass of flexible spongy tissue, is, like sea-tangle, readily moulded into tents which are made use of to dilate the neck of the *uterus*, *fistulous openings*, etc., and which do not so readily become offensive as sponge tents. They have also been saturated with various medicinal extracts and used as vaginal and rectal suppositories. (Their preparation is described by Tuckerman, *Boston Med. and Surg. Jour.*, Jan. 1881, p. 46.)

UNGUENTA, *U. S., Br., F. Cod., P. G.*—OINTMENTS.

Pomata, *F. Cod.*—*Pommades*, *Onguents*, *Fr.*; *Salben*, *G.*

Preparation.—Ointments are unctuous preparations of such a consistence that they may be easily rubbed on the skin, and when in contact with it are gradually liquefied. They consist chiefly of benzoated lard or lard, which is combined in some cases with a small quantity (about one-fifth) of wax, yellow wax being very properly preferred by the *U. S. P.* and *P. G.*: in some cases soft paraffin (petrolatum or paraffin ointment, see p. 1138) is used for the base. In the latter case the ointment is prepared by careful trituration; but if wax is a constituent this is first melted by a moderate heat, and the lard added in small quantities, or previously heated to about the same temperature; the ingredients being thoroughly liquefied, the vessel is removed from the fire, and its contents beaten with a spatula or transferred to a warm mortar, and then well stirred with the pestle to prevent the partial separation of the wax. The addition of aqueous liquids, which should not be too cold, is made in small quantities, and with continued stirring or beating, as soon as the ointment begins to assume an opaque appearance. In all cases the operation should be continued until the temperature of the ointment has been reduced to that of the surrounding atmosphere, and until the preparation is perfectly smooth and homogeneous. Solid substances may be incorporated in a similar manner, provided they have been previously reduced to an impalpable powder. But in most cases, and more particularly when the powder is heavy, much better and more uniform ointments are obtained by triturating the solid material until a powder is obtained, adding a small quantity of oil or of the ointment, and continuing the trituration until all signs of grittiness have disappeared; after which the remaining portion of the ointment may be gradually added and thoroughly incorporated. Salts and other substances which are soluble in water are often conveniently combined with the fatty base by dissolving them in a small quantity of hot water and incorporating this solution in a warm mortar, with the ointment gradually added. If extracts are to be added to ointments, they should be thoroughly softened in a warm mortar, by trituration with a little water, before the fat is added in small portions and with continued trituration. Alcoholic liquids, except when used in very small proportion, are less conveniently incorporated with ointments than concentrated aqueous solutions.

Most of the European pharmacopæias make no distinction between cerates and ointments, but designate both classes as *unguenta*. In France the term *onguent* is usually confined to an ointment into the composition of which resinous substances enter, while ointments with a purely fatty base are designated as *pommades*, and, if the base be a mixture of wax and fat, as *cerats*. In Europe olive or almond oil, melted together with some wax, is frequently employed as the base for ointments in preference to lard. (See also *CERATA* (p. 410), *STEATINA* (p. 411), *GLYCERITUM AMYLI* and *GLYCELÆUM* (p. 739).)

Preservation.—With few exceptions, ointments should be prepared extemporaneously when wanted for use. The fats should in all cases be free from incipient rancidity, and, if carefully prepared, the ointments may be kept for a limited time in well-closed vessels and in a cool place, at a temperature of about 15° C. (59° F.).

In addition to the formulas given farther on, the following are contained in *Br. P.* 1885:

UNGUENTUM ACIDI BORICI. Boric acid 1 oz.; soft paraffin 4 oz.; hard paraffin 2 oz.

UNGUENTUM ACIDI SALICYLICI. Salicylic acid 60 gr.; soft paraffin 1080 gr.; hard paraffin 540 gr.

UNGUENTUM EUCALYPTI. Oil of eucalyptus 1 oz.; soft paraffin 2 oz.; hard paraffin 2 oz.

UNGUENTUM GLYCERINI PLUMBI SUBACETATIS. Glycerin of subacetate of lead 3 oz.; soft paraffin 12 oz.; hard paraffin 4 oz.

UNGUENTUM STAPHISAGRIÆ. Stavesacre seeds 4 oz. Crush and macerate them for two hours in benzoated lard 8 oz., melted over a water-bath; strain and cool.

UNGUENTUM, *U. S.*—OINTMENT.

Unguentum simplex, *Br.*; *Unguentum adipis*.—*Simple ointment*, *E.*; *Pommade simple*, *Fr.*; *Wachssalbe*, *G.*

Preparation.—Lard 80 parts (8 oz. av.); Yellow Wax 20 parts (2 oz. av.); to make 100 parts (10 oz. av.). Melt the wax and add the lard gradually; then stir the mixture constantly while cooling.—*U. S.*

White wax 2 oz., benzoated lard 3 oz., almond oil 3 fluidounces. Melt the wax and lard in the oil on a water-bath; then remove the mixture, and stir constantly while it cools.—*Br.*

Off. Prep.—Ung. acidi carbolici, *U. S.*; Ung. antimonii tart., Ung. creasoti, Ung. elemi,

Ung. hydrarg. ammon., Ung. hydrarg. iodidi rubri, *Br.*; Ung. hydrarg. oxidi flavi, Ung. hydrarg. oxidi rubri, *U. S.*; Ung. plumbi carb., Ung. plumbi iodidi, *Br.*

Medical Uses.—Simple ointment, as it was formerly and more appropriately called, is used as a protective for sores and excoriations and to facilitate the introduction of the hand or finger, surgical instruments, etc. into the urethra, vagina, rectum, etc.

UNGUENTUM ACIDI CARBOLICI, *U. S., Br.*—OINTMENT OF CARBOLIC ACID.

Pommade phéniquée, *Fr.*; *Phenolsalbe*, *G.*

Preparation.—Carbolic Acid 10 parts (48 grains); Ointment 90 parts (1 oz. av.); to make 100 parts (1 troyounce). Mix them thoroughly.—*U. S.*

Carbolic acid 60 gr.; soft paraffin 720 gr.; hard paraffin 360 gr. Melt and mix.—*Br.*

Medical Uses.—Carbolic acid ointment has been used in the treatment of *lupus* and other diseases of the skin, but carbolized oil is preferable as a dressing for wounds. It is probable that the proportion of carbolic acid in this ointment, 10 per cent., is excessive, since a 5 per cent. solution in oil has been found the safest as well as the most efficient surgical dressing.

UNGUENTUM ACIDI GALLICI, *U. S.*—OINTMENT OF GALLIC ACID.

Pommade d'acide gallique, *Fr.*; *Gallussäuresalbe*, *G.*

Preparation.—Gallic Acid 10 parts (48 grains); Benzoinated Lard 90 parts (1 oz. av.); to make 100 parts (1 troyounce). Rub the gallic acid with the benzoinated lard, gradually added, until they are thoroughly mixed, avoiding the use of an iron spatula.—*U. S.*

Medical Uses.—Gallic is superior to tannic acid for internal administration in many cases, but for topical use it is so much less efficient that its use in an official ointment appears to be superfluous.

UNGUENTUM ACIDI TANNICI, *U. S.*—OINTMENT OF TANNIC ACID.

Pommade de tannin, *Fr.*; *Tanninsalbe*, *G.*

Preparation.—Tannic Acid 10 parts (48 grains); Benzoinated Lard 90 parts (1 oz. av.); to make 100 parts (1 troyounce). Rub the tannic acid with the benzoinated lard, gradually added, until they are thoroughly mixed, avoiding the use of an iron spatula.—*U. S.*

Medical Uses.—No ointment made with a vegetable astringent is as powerful as a solution of the same substance in water, or even in glycerin. Tannic acid ointment is no exception to the rule. This preparation may, however, be applied on tampons to the vagina, and may be introduced into the rectum, in relaxed states of these parts.

UNGUENTUM ACONITINÆ, *Br.*—OINTMENT OF ACONITINE.

Pommade d'aconitine, *Fr.*; *Aconitinsalbe*, *G.*

Preparation.—Take of Aconitine 8 grains; Rectified Spirit $\frac{1}{2}$ fluidrachm; Benzoated Lard 1 ounce. Dissolve the aconitine in the spirit, add the lard, and mix thoroughly.—*Br.*

Medical Uses.—This powerful local anæsthetic is chiefly of use in *neuralgia* of the superficial nerves, especially of the face and the back. It should be applied, by means of a soft thick brush or small pledget of lint, over the points of emergence and terminal distribution of the affected nerves. It should not be allowed to touch denuded cutaneous surfaces or mucous membranes.

UNGUENTUM ANTIMONII TARTARATI, *Br.*—OINTMENT OF TARTARATED ANTIMONY.

Pomatum stibiatum, *F. Cod.*; *Unguentum tartari stibiati*, *P. G.*; *Unguentum antimonii*, *Ung. stibio-kali tartarici*, *Ung. stibiatum*.—*Antimonial ointment*, *E.*; *Pommade stibiée*, *P. d'Autenrieth*, *Fr.*; *Brechweinsteinsalbe*, *Pockensalbe*, *G.*

Preparation.—Take of Tartarated Antimony, in very fine powder, $\frac{1}{4}$ oz.; Simple Ointment 1 oz.; mix thoroughly.—*Br.*

Tartar emetic 1 part, benzoated lard 3 parts.—*F. Cod.* Tartar emetic 1 part, paraffin ointment 4 parts.—*P. G.*

Medical Uses.—Antimonial ointment is occasionally employed to produce its characteristic pustular eruption in cases requiring vigorous counter-irritation, but the painful ulcers and the sloughs it sometimes occasions, and the permanent scars that it often leaves behind, have caused it to be generally abandoned, and there is no reason for a revival of its use.

UNGUENTUM AQUÆ ROSÆ, U. S.—OINTMENT OF ROSE-WATER.

Unguentum leniens, P. G.—*Cold cream*, E., Fr., G.

Preparation.—Expressed Oil of Almond 50 parts (5 oz. av.); Spermaceti 10 parts (1 oz. av.); White Wax 10 parts (1 oz. av.); Rose-Water 30 parts (3 oz. or 2½ fluid-ounces). Melt together, by means of a water-bath, the oil, spermaceti, and wax; then gradually add the rose-water, stirring the mixture briskly and constantly until it is cool, and continue the stirring until it has become uniformly soft and creamy.—U. S.

Other pharmacopœias direct: Almond oil 215, spermaceti 60, white wax 30, rose-water 60, tincture of benzoin 15 Gm., oil of rose 10 drops.—*F. Cod.* Almond oil 32, spermaceti 5, white wax 4, rose-water 16 parts, oil of rose 1 drop to 50 Gm.—*P. G.*

The successful preparation of this ointment depends mainly on the pains taken in incorporating the materials while cooling; to facilitate the process E. C. Marshall (1875) recommended the use of an ordinary egg-beater. The ointment should be very white, soft, and perfectly homogeneous. If well made it will retain these properties for some time, but gradually it becomes rancid.

Allied Ointments.—*CERATUM GALIENI*, *Cérat de Galien*, *F. Cod.* White wax 1 part, expressed oil of almond 4 parts, distilled rose-water 3 parts. It is prepared in the same manner as cold cream.

CERATUM FLAVUM, *Cérat jaune*, *F. Cod.* Yellow wax 10 Gm., almond oil 35 Gm., water 25 Gm.

CERATUM LAUDANISATUM, *Cérat laudanisé*, *F. Cod.* Sydenham's laudanum 10 Gm., Galen's cerate 90 Gm.

Medical Uses.—Cold cream, as it is commonly called, is an agreeable and efficient protective in cases of *abrasions, ulcers, frost-bite*, and other superficial lesions of the skin. The addition to it of a small proportion of glycerin, and also of benzoic acid, tends both to preserve the ointment longer and to render it more efficient. As thus modified it is one of the best means of protecting the hands and lips from being chapped.

UNGUENTUM ATROPINÆ, Br.—OINTMENT OF ATROPINE.

Pommade d'atropine, Fr.; *Atropinsalbe*, G.

Preparation.—Take of Atropine 8 grains; Rectified Spirit ½ fluidrachm; Benzoated Lard 1 ounce. Dissolve the atropine in the spirit, add the lard, and mix thoroughly.—*Br.*

Medical Uses.—This preparation is, in most cases, preferable to belladonna ointment, on account of its superior cleanliness and the smaller quantity of it that is efficacious. It is chiefly used in superficial *neuralgia*, to relieve other *local pains*, and, applied to the perineum, to allay *urethral* and *rectal* irritation and spasm.

UNGUENTUM BELLADONNÆ, U. S., Br.—OINTMENT OF BELLADONNA.

Pomatum cum extracto belladonnæ, *F. Cod.*; *Pommade belladonnée*, Fr.; *Tollkirschen-salbe*, G.

Preparation.—Alcoholic Extract of Belladonna 10 parts (50 grains); Diluted Alcohol 6 parts (30 grains or 34 minims); Benzoinated Lard 84 parts (420 grains); to make 100 parts (500 grains). Rub the extract with the diluted alcohol until uniformly soft, then gradually add the lard, and mix thoroughly.—U. S.

Other pharmacopœias direct—Alcoholic extract of belladonna 80 grains, benzoated lard 1 oz. av.—*Br.* Extract of belladonna 4 Gm., water 2 Gm., lard 24 Gm.—*F. Cod.*

Allied Ointment.—*POMATUM POPULEUM*, *Pommade de bourgeon de peuplier*, *Onguent populeum*, *F. Cod.* Digest the fresh leaves of belladonna, hyoscyamus, black nightshade, and poppy, of each 5 parts, in lard 40 parts; when the moisture has completely evaporated add poplar-buds 8 parts; digest for a day, express, and strain.

Medical Uses.—Belladonna ointment was originally used in all the cases of *local*

pain, spasm, etc. to which atropia ointment is now applied, and where cleanliness is not imperative it answers nearly as well. It is better suited than the ointment of the alkaloid for application to absorbing surfaces, as the urethra, vagina, rectum, and ulcerated parts.

UNGUENTUM CADMII IODIDI, Br.—OINTMENT OF IODIDE OF CADMIUM.

Pommade d'iodure de cadmium, Fr.; Jodkadmiumsälbe, G.

Preparation.—Take of Iodide of Cadmium, in fine powder, 62 grains; Simple Ointment 1 ounce. Mix thoroughly.—*Br.*, 1867.

Medical Uses.—This ointment is reputed to be stimulating and resolvent. It has been applied to enlarged glands in the same manner as iodide of lead ointment. It has the advantage over the latter preparation of not staining the skin.

UNGUENTUM CANTHARIDIS, Br.—OINTMENT OF CANTHARIDES.

Unguentum cantharidum, P. G.; Pomatum cum cantharide, F. Cod.; Ung. irritans, Ung. ad fongiculos.—Pommade épispastique, Fr.; Spanischfliegensalbe, G.

Preparation.—Take of Cantharides, Yellow Wax, of each 1 ounce; Olive Oil 6 fluidounces. Infuse the cantharides in the oil in a covered vessel for 12 hours; then place the vessel in boiling water for 15 minutes, strain through muslin with strong pressure, add the product to the wax, previously melted, and stir constantly while the mixture cools.—*Br.*

Coarsely-powdered cantharides 2 parts, olive oil 8 parts; digest, express, filter, and to 7 parts of the filtrate add 3 parts of yellow wax.—*P. G.*

The ointment was dismissed from the U. S. P. 1880. Cantharidin being readily soluble in fats, the ointment prepared by digesting cantharides in olive oil has the active principle more uniformly diffused than by incorporating powdered cantharides with ointment. Cerate of extract of cantharides is well adapted for preparing this ointment extemporaneously; it has a greenish-yellow color.

Allied Ointment.—UNGUENTUM ACRE. Melt together yellow wax 15 parts, resin 30 parts, turpentine 60 parts, and lard 250 parts; add powdered cantharides 50 parts, and powdered euphorbium 10 parts; mix, and stir until cool.—*P. G.* 1870.

The French Codex recognizes a yellow and a green cantharides ointment, of which the former is prepared by infusing cantharides 1 part in melted lard 14 parts, adding a little turmeric, filtering, melting together with yellow wax 2 parts, and adding a little oil of lemon. The green ointment is a mixture of powdered cantharides 1 part, poplar ointment (see UNG. BELLADONNÆ) 28 parts, and wax 4 parts.

Medical Uses.—Ointment of cantharides is intended to be used as a dressing for recently blistered surfaces, in order to prolong the discharge from them, and also to act as a rubefacient upon the sound skin when blistering is not desirable. In this manner it may sometimes be applied in muscular rheumatism, in partial paralysis, and in alopecia. But in all these cases various stimulant liniments are more suitable. In many cases also for which this ointment is appropriate the plaster of Burgundy pitch with cantharides is much more efficient.

UNGUENTUM CETACEI, Br.—OINTMENT OF SPERMACETI.

Onguent de blanc de baleine, Fr.; Walratsalbe, G.

Preparation.—Melt together Spermaceti 5 oz., White Wax 2 oz., and Almond Oil 1 pint (Imper.); add Benzoin in coarse powder $\frac{1}{2}$ oz., and, frequently stirring the mixture, continue the application of heat for 2 hours; strain the mixture and stir constantly until quite cold.—*Br.*

Except in consistence it resembles spermaceti cerate (p. 412).

Medical Uses.—This ointment, when freshly made, is an appropriate dressing for wounds, excoriations, and blisters.

UNGUENTUM CHRYSAROBINI, U. S., Br.—CHRYSAROBIN OINTMENT.

Pommade de chrysarobine, Fr.; Chrysarobinsalbe, G.

Preparation.—Chrysarobin 10 parts (48 grains); Benzoinated Lard 90 parts (1 oz. av.); to make 100 parts (1 troyounce). Mix thoroughly by trituration.—*U. S.*

Melt benzoated lard 480 grains, add chrysarobin 20 grains, and stir them together, maintaining a moderate temperature, so as to promote solution; then stir until cold.—*Br.*

This ointment has been admitted as a more uniform preparation than the *araroba ointment* originally proposed by Da Silva Lima. Balmano Squire (1877) recommended the solution of chrysarobin in lard to be effected by heating in a water-bath with benzol, and the latter to be evaporated by stirring the liquid in a warm dish while cooling and congealing. The ointment is of a yellow color, and should be entirely free from grittiness.

Medical Uses.—The various applications of this ointment are described under CHRYSAROBIN.

UNGUENTUM CREASOTI, *Br.*—OINTMENT OF CREASOTE.

Pommade créosotée, Fr.; Kreosotsalbe, G.

Preparation.—Take of Creasote 1 fluidrachm; Simple Ointment 1 ounce. Mix thoroughly.—*Br.*

Medical Uses.—Creasote ointment is a protective, and, like creasote-water, a wholesome stimulant in numerous cases, including *burns, chilblains, ulcers* of various descriptions, and especially those which have flabby, fungous granulations, an ichorous secretion, a tendency to gangrene, or a connection with carious bone. Even for *cancerous* ulcers it forms an eligible dressing, especially after they have been washed with creasote-water. Indeed, the applications of the latter, enumerated elsewhere, are, *mutatis mutandis*, those of creasote ointment.

UNGUENTUM DIACHYLON, *U. S., P. G.*—DIACHYLON OINTMENT.

Unguentum plumbi Hebræ.—Hebra's lead ointment, *E.*; *Onguent diachylon, Fr.; Diachylonsalbe, G.*

Preparation.—Lead Plaster 60 parts (300 grains); Olive Oil 39 parts (195 grains); Oil of Lavender 1 part (5 grains or 6 minims); to make 100 parts (500 grains). Melt together the lead plaster and olive oil at a moderate heat; then, having permitted the mass to become partly cool, incorporate with it the oil of lavender, and stir constantly until cold.—*U. S.*

Lead plaster 5 parts; free it from glycerin by washing, and from water by heating on a water-bath; melt it at a moderate heat with olive oil 5 parts; stir until cold, and after several hours stir again.—*P. G.*

The first formula is that of the Swiss Pharmacopœia. The second formula is an improvement upon that of the *P. G.* 1872, in replacing the linseed oil formerly used by olive oil, and in freeing the ointment completely from water and hygroscopic glycerin for the purpose of decreasing its liability to rancidity. If properly prepared, the ointment is nearly white and will keep unaltered for several weeks.

Medical Uses.—Speaking of the treatment of *eczema*, Hebra said of this ointment, "I have called it *Ung. diachyli*, and prescribed it either alone or in combination with balsam of Peru. It is either applied by means of the finger or rubbed in with balls of charpie from one to three times a day; or, if it be desirable to increase its effect, it may be spread on linen or flannel and applied like a plaster" (*Diseases of the Skin*, Sydenham Soc. ed., ii. 151). The eminent dermatologist recommends this ointment in *fetid sweating* of the feet (*Ibid.*, i. 89) and as a part of the treatment of *sycosis menti* (*Ibid.*, ii. 317).

UNGUENTUM ELEMI, *Br.*—OINTMENT OF ELEMI.

Unguentum (Balsamum) Arcæi, F. Cod.—*Onguent (Baume) d'Arcæus, Fr.; Elemi-salbe, G.*

Preparation.—Take of Elemi $\frac{1}{2}$ ounce; Simple Ointment 1 ounce. Melt, strain through flannel, and stir constantly until the ointment solidifies.—*Br.*

Elemi and Venice turpentine, each 15 parts, suet 20 parts, lard 10 parts; melt, strain, and stir until cold.—*F. Cod.*

Medical Uses.—Ointment of elemi is a mild local stimulant, and as such may be used as a dressing for slightly indolent *ulcers* and for maintaining the suppuration of issues and setons. Formerly an ointment known as *Balsamum Arcæi*, and containing elemi and larch turpentine in equal proportions, was used for the same purpose, and, except in trifling cases, probably with more effect.

UNGUENTUM GALLÆ, U. S., Br.—OINTMENT OF NUTGALL.

Pommade de noix de galle, Fr. ; Galläpfelsalbe, G.

Preparation.—Nutmall, in No. 80 powder, 10 parts (48 grains); Benzoinated Lard 90 parts (1 oz. av.); to make 100 parts (1 troyounce). Rub the nutgall with the benzoinated lard, gradually added, until they are thoroughly mixed.—*U. S.*

Galls, in fine powder, 80 grains; benzoated lard 1 oz. av. Mix thoroughly.—*Br.*

Medical Uses.—Ointment of nutgall, like that of tannic acid, its active component, is appropriately applied to relaxed tissues, but especially to those of the *vagina* and *rectum*, to prevent or diminish *prolapsus* of these parts. In the latter case, when *piles* exist, an ointment composed of equal parts of the ointments of nutgall and stramonium and Goulard's cerate is a very efficient remedy.

UNGUENTUM GALLÆ CUM OPIO, Br.—OINTMENT OF GALLS AND OPIUM.

Preparation.—Take of Ointment of Galls 1 ounce; Opium, in powder, 32 grains. Mix thoroughly.—*Br.*

Medical Uses.—This preparation is intended to fulfil the same indications as those of the compound ointment mentioned under *UNGUENTUM GALLÆ*, but it is far less efficient as applied to the anus, and, owing to the large proportion of opium it contains, not without danger if introduced into the vagina or the rectum.

UNGUENTUM HYDRARGYRI, U. S., Br.—MERCURIAL OINTMENT.

Unguentum hydrargyri cinereum, P. G. ; Pomatum cum hydrargyro, F. Cod. ; Unguentum mercuriale s. neapolitanicum.—Ointment of mercury, Blue ointment, E. ; Pommade (Onguent) mercurielle à parties égales, P. napolitaine, Fr. ; Graue Quecksilbersalbe, G.

Preparation.—Mercury 450 parts (9 oz. av.); Lard 225 parts (4½ oz. av.); Suet 225 parts (4½ oz. av.); Compound Tincture of Benzoin 40 parts (350 grains or 6½ fluidrachms); Mercurial Ointment 100 parts (2 oz. av.); to make 1000 parts (18 oz. av.). Mix the mercury with the tincture of benzoin in a mortar, add the mercurial ointment (which should contain 50 per cent. of mercury), and triturate the mixture until globules of mercury cease to be visible; then add the lard and suet, previously melted together and partially cooled, and continue the trituration until globules of mercury cease to be visible under a magnifying power of ten diameters.—*U. S.*

Mercury, prepared lard, each 1 pound; prepared suet 1 ounce; rub them together until metallic globules cease to be visible.—*Br.*

Mercury and benzoinated lard equal parts. Melt the lard, pour about one-third of it into an iron vessel, and keep it at a temperature so as to remain sufficiently soft; add the mercury very gradually, triturate until extinct, add the remainder of the lard, and continue the trituration until a perfect mixture is obtained.—*F. Cod.*

The German Pharmacopœia has a similar process, but uses lard and mutton-suet in the proportion of 13 : 7, and incorporates with this mixture 10 parts of mercury. This ointment contains one-third its weight of mercury, globules of which should not be visible to the naked eye.

With the exception of the French Codex, the pharmacopeias have very properly discarded *weak mercurial ointment*, leaving the physician to order the dilution of the strong ointment as he may think necessary.

The extinguishment of the mercury, if the directions of the last three formulas are literally followed, requires such a long time that few pharmacists will undertake the trouble of preparing the ointment. It may be hastened by the addition of a little sulphur or soft turpentine, yet to both there are serious objections—to the former, on account of forming an inert black sulphide; to the latter, on account of its irritating properties. The substitution of wax, spermaceti, stearin, cacao butter, and of similar solid fats and allied compounds for part of the lard answers the purpose but partially, and is more effectual with small than with larger quantities. The same is true if the mercury, finely divided by pressing it with a moderate force through chamois leather, is sprinkled on the semi-solid fat and incorporated without delay. On triturating mercury with a small quantity of liquid storax or with a mixture of liquid storax and lard, it is rapidly extinguished to such an extent that the metallic globules are not visible under a power of two

or three diameters. Tincture of Tolu triturated with the mercury in the presence of a portion of the lard has a similar effect. But even such ointments have been objected to as being too irritating. Trituration with lard and oil of turpentine has also been recommended, but the latter does not evaporate as readily as has been supposed, and imparts to the ointment for a long time a turpentine odor. Higginbottom (1813) observed that the extinguishment of mercury is facilitated by means of mercurial ointment, usually through the incipient or more advanced rancidity of the fat contained in the ointment; and a similar result may be obtained by using about 5 or 10 per cent. of rancid fat in place of an equal amount of lard; but Buchner (1834) and others have shown that the mercurial ointment used for this purpose need not, and should not, be rancid. The formula of the U. S. P., which was proposed by Prof. Remington, makes use of both the ready-made ointment and of storax, the latter contained in the tincture ordered, for rapidly extinguishing the mercury; during the trituration the alcohol gradually evaporates, and the small amount of balsamic matter remaining behind tends to preserve the ointment from becoming rancid.

The objection to many of these additions has been their irritating properties. This cannot be urged against the use of ether, as proposed by Renoult. On mixing lard with about one-tenth of ether, and triturating this with mercury, the metal will be readily extinguished, and the ointment may be finished by incorporating the softened suet. Glycerin, glycerite of starch, and diastase have also been suggested for facilitating the extinguishment of the mercury. Chevallier (1826) proposed agitation of mercury with one-half of the liquefied fat in a strong bottle, and subsequently adding the remaining fat by trituration; in this manner, he stated, 1 pound of the ointment could be prepared in 30 minutes. Others were not as successful; according to Häfner (1829), the extinguishment of mercury by succussion by means of the machinery of a saw-mill required 4 days, but the manual labor required did not exceed 1 hour. An apparatus for preparing the ointment in a similar manner has been constructed by Dr. Squibb (*Proc. Amer. Phar. Assoc.*, 1859, p. 359).

A clean iron mortar is well adapted for the preparation of this ointment on a limited scale, though a small portion of the mercury will superficially combine with the iron. A Wedgewood or marble mortar does not occasion even this slight loss.

The extinguishment of the mercury is most readily observed by the use of a lens of moderate power, or by rubbing a small portion of the ointment between folded paper, when no metallic globules should become visible to the naked eye. Rhigini observed that on triturating a little of the ointment in a marble mortar with a wooden pestle until the ointment has been absorbed, the pestle will have a bright metallic surface in case the mercury had not been completely extinguished.

• On keeping mercurial ointment at a temperature at which it becomes soft without liquefying, it will slowly alter in composition in such a manner that the lower strata contain a larger proportion of mercury than the upper ones. Hence it is necessary in warm weather to employ fat or a mixture of fats having a higher fusing-point than lard, such as is directed by the U. S. Pharmacopœia.

When made with fresh and sweet fats the ointment contains the mercury in a minutely divided condition. As rancidity commences and increases, a portion of the mercury will be found in chemical combination, and this amount is increased at an elevated temperature. It follows from this that mercurial ointment should be kept in a cool place and in a well-closed jar, and that it may be still further protected by covering the surface of the ointment with paper which has been saturated with tincture of Tolu or tincture of storax.

Off. Prep.—Linim. hydrargyri, Suppos. hydrargyri, Ung. hydrarg. comp., *Br.*

Medical Uses.—By means of this ointment, duly rubbed upon the skin, the constitutional effects of mercury can be secured without as much risk of disordering the digestion of the patient as when mercury in any of its forms is given by the mouth. This was at one time the chief method of treating constitutional and even primary *sypilis*, and, in spite of its being "dirty, laborious, and troublesome," it is better than any other form of mercurial treatment, since "it cures the disease better, and does not damage the constitution half so much" (Brodie). Theunctions should be made upon different parts of the body successively, as the thighs, the flanks, the arms, the chest, and usually before a fire or in the direct sunlight. 1 or 2 drachms should be rubbed in daily; the patient should be clothed in flannel, sleep between blankets, and every two or three days cleanse the skin with a bath of warm water and soap. If he is able he should make the friction with his own hands; and if he cannot do this, the hands of the attendant making

them should be protected by a caoutchouc glove or by a pig's bladder previously softened with warm water. In other cases, and especially when mercurial ointment is employed to supplement the internal use of mercurials, it may be spread upon a cloth and applied to a recently blistered surface. In cases of infantile syphilis a flannel roller smeared with the ointment may be secured around the body of the patient.

All chronic superficial *swellings* resulting from inflammation have their absorption hastened by frictions made with mercurial ointment. This treatment is peculiarly appropriate in *glandular* and other swellings arising from syphilitic infection, but it is sometimes also used to promote the resolution of chronic engorgement of the *liver* or *spleen*. *Paronychia* may be prevented from suppurating by frictions with mercurial ointment made every hour for five minutes at a time, while in the interval the part is kept enveloped in a poultice. In subacute and chronic inflammation of the joints much benefit has been derived from wrapping them, previously blistered or not, in cloths spread with mercurial ointment, and keeping them at rest by means of appropriate splints. A like advantage sometimes accrues in chronic or subacute *orchitis* from covering the affected organ in a similar manner. But the simple ointment is less efficacious than that of the iodide of mercury. There can be no doubt that mercury, applied in one form or another to an eruption of *small-pox* upon the face during its papular stage sometimes prevents the papules from maturing and leaving scars. The ointment may be spread, alone or rendered more tenacious by the admixture of starch, upon linen, with suitable apertures for the nostrils and mouth, and closely applied to the face like a mask. It has been used after the same manner in the treatment of *erysipelas* of the face, but, on the whole, without advantage, and frequently with the effect of causing salivation. It is also a palliative of *prurigo pudendi*, but in this case it is open to the same objection. Unna recommends for common warts and *condylomata acuminata* the continuous application of mercurial ointment containing 5 per cent. of arsenic. This dressing is said not to irritate the part, but to cause the warts to wither (*Boston Med. and Surg. Jour.*, Oct. 1882, p. 321).

UNGUENTUM HYDRARGYRI AMMONIATI, U. S., Br.—OINTMENT OF AMMONIATED MERCURY.

Unguentum hydrargyri præcipitati album, P. G.—*Pommade de mercure précipité blanc*, Fr.; *Weisse Quecksilbersalbe*, G.

Preparation.—Ammoniated Mercury, in very fine powder, 10 parts (48 grains); Benzoinated Lard 90 parts (1 oz. av.); to make 100 parts (1 troyounce). Rub the ammoniated mercury with the benzoinated lard, gradually added, until they are thoroughly mixed.—U. S.

Ammoniated mercury 50 grains; simple ointment 450 grains.—Br. Ammoniated mercury 1 part; paraffin ointment 9 parts.—P. G.

Medical Uses.—Ammoniated mercurial ointment is used as a stimulant in cases of chronic *blepharitis* and in several cutaneous affections, especially in *psoriasis* of limited extent and in those of parasitic origin, including *ringworm* of the scalp (*porrigo scutulata*). In *herpes circinatus*, *sycosis*, and *pityriasis* it is also employed. In *herpes zoster* it has been reported, on insufficient grounds, to be useful. It is more efficacious in chronic forms of circumscribed *eczema* and of tubercular and squamous *syphilis*. Like other mercurial ointments, it is a destroyer of *lice*. It has over the others the advantage of cleanliness, and it may be perfumed with some agreeable essential oil, such as lavender or bergamot.

UNGUENTUM HYDRARGYRI COMPOSITUM, Br.—COMPOUND OINTMENT OF MERCURY.

Pommade mercurielle composée, Fr.; *Kampfer-Quecksilbersalbe*, G.

Preparation.—Take of Ointment of Mercury 6 ounces; Yellow Wax, Olive Oil, each 3 ounces; Camphor 1½ ounces. Melt the wax with a gentle heat, and add the oil; then, when the mixture is nearly cold, add the camphor in powder and the ointment of mercury, and mix the whole thoroughly together.—Br.

The ointment has a greenish tint, and is softened by the camphor.

Medical Uses.—It is impossible to discover any sufficient reason for the existence of this preparation, which probably has the virtues, and no others, of simple mercurial ointment.

UNGUENTUM HYDRARGYRI IODIDI RUBRI, *Br.*—OINTMENT OF RED IODIDE OF MERCURY.

Pommade d'iodure mercurique, Fr.; Jodquecksilbersalbe, G.

Preparation.—Take of Red Iodide of Mercury, in fine powder, 16 grains; Simple Ointment 1 ounce. Mix thoroughly.—*Br.*

Medical Uses.—This ointment is chiefly used as a stimulant of indolent *scrofulous* and *syphilitic ulcers* and *scrofulous glandular swellings*. In India *goitre* has been cured in many thousands of cases by rubbing into the tumor an ointment made with 60 grains of red iodide of mercury to a pound of lard, and then exposing the patient for several hours to the direct action of the sun. The operation is repeated twice a day for several days, the applied ointment being allowed to remain (Macnamara, *Dublin Quart. Jour.*, Nov. 1857, p. 500). A very similar method has been employed with remarkable success in the treatment of enlargement of the *liver* and *spleen*, the heat of a fire being substituted for that of the sun.

UNGUENTUM HYDRARGYRI NITRATIS, *U. S., Br.*—OINTMENT OF NITRATE OF MERCURY.

Pomatum citrinum, F. Cod.; Unguentum hydrargyri citrinum, Unguentum citrinum.—Citrine ointment, E.; Pommade citrine, Onguent citrin, Fr.; Quecksilbernitratsalbe, G.

Preparation.—Mercury 7 parts ($1\frac{1}{2}$ oz. av.); Nitric Acid 17 parts ($3\frac{3}{4}$ oz. av.); Lard Oil 76 parts ($16\frac{1}{4}$ oz. av.). Heat the lard oil in a glass or porcelain vessel to a temperature of 70° C. (158° F.); then add, without stirring, 7 parts ($1\frac{1}{2}$ oz. av.) of nitric acid; continue the heat so long as a moderate effervescence continues, and allow the mixture to cool. Dissolve the mercury in the remainder of the nitric acid with the aid of sufficient heat to prevent the solution from crystallizing; add this solution to the mixture before it has become entirely cold, and mix them thoroughly, avoiding the use of an iron spatula.—*U. S.*

Take of mercury, by weight, 4 ounces; nitric acid 12 fluidounces; prepared lard 15 ounces; olive oil 32 fluidounces. Dissolve the mercury in the nitric acid with the aid of a gentle heat; melt the lard in the oil, by a steam- or water-bath, in a porcelain vessel capable of holding six times the quantity, and, while the mixture is at about 100° C., add the solution of mercury, also at about the same temperature, mixing them thoroughly. If the mixture do not froth up, increase the heat till it occurs. Keep it stirred until it is cold.—*Br.*

On mixing melted fats with a solution of mercuric nitrate containing free nitric acid a very complicated reaction takes place, resulting, on the one hand, in the oxidation of the fat and the evolution of nitric oxide (nitrogen dioxide) and hyponitric acid (nitrogen tetroxide), and, on the other hand, in the conversion by the latter of the olein contained in the fat into solid elaidin. The products of oxidation of the fat contain various volatile fatty acids, but must necessarily vary with the nature of the fat, the amount of free nitric acid, and the degree of the heat. Should the nitric acid be insufficient in quantity or the temperature rise to too high a degree, the oxidation is effected in part at the expense of the mercuric nitrate, which is thereby reduced to mercurous salt. The second formula given above orders a much larger quantity of nitric acid than is necessary, and indicates about 100° C. as the temperature at which the fat should be mixed with the mercuric solution. According to the temperature at which the nitric acid acts upon the mercury, the solution will contain mercurous or mercuric nitrate, or both salts, with or without hyponitric acid. If free from mercurous nitrate, the solution will yield with lard at 200° F. a citrine ointment having, at least at first, a bright-yellow color. In our experience an equally good and permanent ointment is obtained by heating both the mercuric solution and the fat to about 70° C. (158° F.) before mixing them; and even a lower degree of heat, about 50° C. (122° F.), will produce good results if the reaction is completed before the ointment is permitted to cool. All difficulties are, however, overcome by following the process suggested by R. Rother (1870), and which has been adopted by the U. S. P., using lard oil in the place of the neat's foot oil and lard formerly employed. Unsalted butter and many other fats, the drying oils excepted, similarly treated, will yield an equally handsome ointment. The French Codex directs 1 part of mercury and 2 parts of nitric acid to 20 parts of fat composed of equal weights of lard and olive oil; this salve is firm, and is sold in the form of square cakes.

Citrine ointment should be prepared in glass or porcelain vessels, and should not be brought into contact with iron or other metal.

Allied Ointment.—UNGUENTUM NITRICUM, Ung. oxygenatum, *P. G.* 1872. Melt 50 parts of lard, add 3 parts of nitric acid spec. grav. 1.185, and heat slowly and with constant stirring until the reaction ceases; then pour into paper moulds (see page 411). It is of a light-yellow color.

UNGUENTUM HYDRARGYRI NITRATIS DILUTUM, *Br.* Mix nitrate of mercury ointment 1 ounce with soft paraffin 2 ounces.

Medical Uses.—Citrine ointment is employed in nearly all of the cases mentioned under the head of white precipitate ointment, but especially in chronic diseases of the *skin*, and in the affections enumerated under ointment of red oxide of mercury. It is more stimulating than the former preparation, and generally needs dilution with lard. It is very apt to occasion salivation.

UNGUENTUM HYDRARGYRI OXIDI FLAVI, *U. S.*—OINTMENT OF YELLOW OXIDE OF MERCURY.

Pommade d'oxyde jaune de mercure, Fr.; Gelbe Quecksilberoxydsalbe, G.

Preparation.—Yellow Oxide of Mercury, in very fine powder, 10 parts (48 grains); Ointment 90 parts (1 oz. av.); to make 100 parts (1 troyounce). Rub the oxide of mercury with the ointment, gradually added, until they are thoroughly mixed.—*U. S.*

Yellow oxide of mercury 1 part, petrolatum 15 parts.—*F. Cod.*

The yellow wax contained in the simple ointment will protect this preparation from rancidity, but it is best to keep the ointment on hand for a short time only or to prepare it when needed.

Medical Uses.—This preparation was introduced as a substitute for ointment of the red oxide of mercury, with which it is identical in its medicinal qualities; but owing to the amorphous condition and the greater fineness of subdivision of the particles of the oxide from which it is made, it appears to be more suitable for application to the *eye* and other delicate tissues.

UNGUENTUM HYDRARGYRI OXIDI RUBRI, *U. S., Br.*—OINTMENT OF RED OXIDE OF MERCURY.

Unguentum hydrargyri rubrum, P. G.; Pomatum cum oxydo hydrargyrico, F. Cod.; Ung. præcipitatum rubrum.—Pommade d'oxyde rouge de mercure, Pommade de Lyon, Baume ophtalmique rouge, Fr.; Rothe Quecksilbersalbe, G.

Preparation.—Red Oxide of Mercury, in very fine powder, 10 parts (48 grains); Ointment 90 parts (1 oz. av.); to make 100 parts (1 troyounce). Rub the oxide of mercury with a small quantity of the ointment until a perfectly smooth mixture is obtained; then gradually add the remainder of the ointment, and mix thoroughly.—*U. S.*

Take of red oxide of mercury, in very fine powder, 62 grains; hard paraffin $\frac{1}{4}$ ounce; soft paraffin $\frac{3}{4}$ ounce. Melt the hard and soft paraffins together, and when the mixture in cooling begins to thicken add the oxide of mercury in a glass or porcelain mortar, and mix the whole thoroughly.—*Br.*

Red oxide of mercury 1 part, petrolatum 15 parts, *F. Cod.* (paraffin ointment 9 parts, *P. G.*).

Made with finely-levigated oxide, the ointment has an orange color, and if good yellow wax be used remains unaltered for some months. The addition of alkali for neutralizing incipient rancidity, or the substitution of ointment made with castor oil or almond oil for the pharmacopœial ointment, is unnecessary.

Allied Ointments.—UNGUENTUM OPHTHALMICUM, *P. G.* 1872. Melt together 30 parts of expressed oil of almond and 19 parts of yellow wax, and mix these intimately with 1 part of very finely levigated oxide of mercury.

UNGUENTUM OPHTHALMICUM COMPOSITUM, s. Ung. ophtalmicum St. Yves, *P. G.* 1872. Melt together lard 140 parts and yellow wax 24 parts; add red oxide of mercury 15 parts and pure oxide of zinc 6 parts; and mix thoroughly with camphor 5 parts, previously dissolved in expressed oil of almond 10 parts.

POMATUM DR. REGENT.—Pommade de Régent, *F. Cod.*—Red oxide of mercury 1 Gm.; acetate of lead 1 Gm.; camphor 0.10 Gm.; petrolatum 18 Gm.

Medical Uses.—Red precipitate ointment, when used as a dressing for *ulcers*, is very apt to produce the specific effects of mercury upon the system. It should not, therefore, be too freely applied nor upon too large a surface at once. Its use is very much restricted to the treatment of indolent *syphilitic sores* and chronic inflammations of the edges of the eyelids (*blepharitis*). For the latter purpose the ointment should be

diluted. 1 part of red precipitate ointment to 8 or 10 of simple ointment is usually strong enough.

UNGUENTUM HYDRARGYRI SUBCHLORIDI, *Br.*—OINTMENT OF SUBCHLORIDE OF MERCURY.

Unguentum calomelanos.—*Pommade de chlorure mercurique, P. de calomel.* Fr.; *Quecksilberchlorürsalbe,* G.

Preparation.—Take of Subchloride of Mercury 80 grains; Benzoated Lard 1 ounce. Mix thoroughly.—*Br.*

Calomel 1 part, benzoinated lard 9 parts.—*F. Cod.* This ointment, being known in France also as *pommade au précipité blanc*, should not be confounded with the ointment of ammoniated mercury (see also pp. 775 and 795).

Medical Uses.—Calomel ointment has the advantage over all the ointments made with salts of mercury of being wholly unirritating, and over simple mercurial ointment of not discoloring the skin or staining the clothing. It is therefore adapted to the local treatment of *cutaneous eruptions* of limited extent, and especially to those of a *symphilitic* nature. It is conveniently associated with white precipitate ointment in the affections to which that ointment is applied.

UNGUENTUM IODI, *U. S., Br.*—IODINE OINTMENT.

Unguentum iodinii, U. S. 1870.—*Pommade d'iode,* Fr.; *Jodsalbe,* G.

Preparation.—Iodine 4 parts (18 grains); Iodide of Potassium 1 part (4½ grains); Water 2 parts (10 minims); Benzoinated Lard 93 parts (420 grains); to make 100 parts (450 grains). Rub the iodine and iodide of potassium first with the water, and then with the benzoinated lard, gradually added, until they are thoroughly mixed, avoiding the use of an iron spatula.—*U. S.*

Iodine and iodide of potassium each 32 grains; glycerin 1 fluidrachm; prepared lard 2 oz. av.—*Br.*

The water and potassium iodide are serviceable for effecting the fine division of the iodine. The lard should be added at first in very small quantities, and the trituration continued until the solid ingredients are perfectly levigated and the mixture is entirely free from grittiness and uniform in color.

Allied Ointment.—*UNGUENTUM IODINII COMPOSITUM,* U. S. 1870: Pomatum cum iodureto potassico iodurato. *F. Cod.*—Compound iodine ointment, *E.*; *Pommade d'iodure de potassium ioduré.* Fr.; *Jodkaliumsalbe mit Jod,* G.—Iodine 15 grains; iodide of potassium 30 grains; water 30 minims; lard a troyounce.—*U. S.* 1870. Iodine 2, iodide of potassium 10, water 10, and benzoinated lard 80 parts.—*F. Cod.*

Medical Uses.—Iodine ointment has been employed extensively to promote the absorption of the exudation occurring in local inflammations. It is used in indolent enlargement of the *tonsils*, the *thyroid*, and the *lymphatic glands*; also in *hydrarthrosis*, *cold abscess*, and chronic *peritonitis*. It may be applied to the *mammary gland* when abscess threatens to form in that gland, to promote the absorption of *pleural* and *pericardial effusions*, to prevent the development of inflammation in *tendinous sheaths*, that of *chilblains*, etc.

Compound iodine ointment, it will be observed, contains less iodine than the simple ointment. The advantage of the iodide of potassium in it must depend upon the absorption of the salt, which cannot be very great from the limited surfaces to which the ointment is usually applied. The compound and the simple ointments are used in the same affections.

UNGUENTUM IODOFORMI, *U. S., Br.*—IODOFORM OINTMENT.

Pommade d'iodoforme, Fr.; *Jodoformsalbe,* G.

Preparation.—Iodoform, in very fine powder, 10 parts (48 grains); Benzoinated Lard 90 parts (1 oz. av.); to make 100 parts (1 troyounce). Rub the iodoform with the benzoinated lard, gradually added, until they are thoroughly mixed.—*U. S.*

Dissolve iodoform 1 ounce in melted benzoated lard 9 ounces and cool.—*Br.*

The ointment should be perfectly smooth and free from grittiness; it has a light-yellow color and the peculiar odor of iodoform. (For disguising the odor consult pp. 827, 831.)

Allied Preparation.—CRAYONS D'IODOFORME, *F. Cod.*, Iodoform pencils. Triturate iodoform 20 parts with powdered acacia 1 part, and by means of very little water and glycerin form a mass of pilular consistence which is rolled out into cylinders of suitable size.—*F. Cod.* Butter of cacao may be used with an equal weight of iodoform; these pencils are dusted with lycopodium.

Medical Uses.—Under IODOFORM the numerous applications of this ointment have been mentioned. It is anæsthetic and stimulant.

UNGUENTUM MEZEREI, *U. S.*—MEZEREON OINTMENT.

Pommade épispastique au garou, Fr.; Seidelbastsalbe, G.

Preparation.—Fluid Extract of Mezereon 25 parts (100 grains); Lard 80 parts (1 lb. av.); Yellow Wax 12 parts (48 grains). Melt together the lard and wax with a moderate heat, add the fluid extract, and stir the mixture constantly until the alcohol has evaporated; then continue to stir until cool.—*U. S.*

Extract of mezereon 4 parts; dissolve in alcohol 9 parts, and add to a melted mixture of lard 90 and wax 10 parts.—*F. Cod.*

Medical Uses.—Mezereon ointment is employed for the purpose of maintaining a discharge from suppurating surfaces created by *cantharides*, *caustics*, *setons*, *issues*, and other irritants.

UNGUENTUM PICIS LIQUIDÆ, *U. S., Br.*—TAR OINTMENT.

Pomatum cum pice, F. Cod.—Pommade de goudron, Fr.; Theersalbe, G.

Preparation.—Tar, Suet, each 50 parts (8 oz. av.); to make 100 parts (1 lb. av.). Mix the tar with the suet previously melted with a moderate heat, and, having strained the mixture through muslin, stir it constantly until cool.—*U. S.*

Tar 5 ounces; yellow wax 2 ounces; melt the wax with a gentle heat, add the tar, and stir the mixture briskly while it cools.—*Br.*

Tar 1 part, lard 9 parts; mix.—*F. Cod.*

Allied Ointment.—UNGUENTUM PICIS BETULÆ, *s. U. RUSCI*, Wolff's tar ointment. Birch tar (see p. 1182) 8 Gm., simple ointment 42 Gm.

Medical Uses.—Tar ointment will sometimes cure *scabies*, but its action is uncertain and dilatory. In scaly eruptions, as *psoriasis* and *lepra*, its efficacy is much more decided, as well as in *chronic eczema* after the liquid secretion has ceased. In *ringworm* and in *prurigo* it is one of the best applications, and it may be used with advantage in the greater number of indolent and gangrenous *ulcers*.

UNGUENTUM PLUMBI ACETATIS, *Br.*—OINTMENT OF ACETATE OF LEAD.

Preparation.—Take of Acetate of Lead, in fine powder, 12 grains; Benzoated Lard 1 oz. av. Mix thoroughly.—*Br.*

Allied Ointments.—UNGUENTUM NARCOTICO-BALSAMICUM HELLMUNDI, Hellmund's ointment. Triturate together acetate of lead 10 parts and extract of conium 30 parts; add gradually simple ointment 240 parts, balsam of Peru 30 parts, and wine of opium (with saffron) 5 parts, and mix thoroughly.—*P. G.* 1872.

UNGUENTUM PLUMBI TANNICI (see page 1192).

Medical Uses.—The action and uses of acetate of lead ointment are probably identical with those of the cerate of subacetate of lead. It is applied as a dressing to *wounds*, *excoriations*, and *inflamed surfaces* generally.

UNGUENTUM PLUMBI CARBONATIS, *U. S., Br.*—OINTMENT OF CARBONATE OF LEAD.

Pomatum cum carbonate plumbico, F. Cod.; Unguentum cerussæ, s. Ung. album simplex, P. G.—Pommade de carbonate de plomb, Ouguent blanc de Rhazès, Fr.; Bleiweissalbe, G.

Preparation.—Carbonate of Lead, in very fine powder, 10 parts (48 grains); Benzoated Lard 90 parts (1 oz. av.); to make 100 parts (1 troyounce). Rub the carbonate of lead with the benzoated lard, gradually added, until they are thoroughly mixed.—*U. S.*

Other pharmacopœias direct: Carbonate of lead 62 grains; simple ointment 1 oz. av.—*Br.* Carbonate of lead 1 part; benzoinated lard 5 parts.—*F. Cod.* Carbonate of lead 3 parts; paraffin ointment 7 parts.—*P. G.*

Allied Ointment.—UNGUENTUM CERUSSE CAMPHORATUM. Ointment of carbonate of lead 95 parts, powdered camphor 5 parts.—*P. G.*

Medical Uses.—It is used for the same purposes as the last-mentioned ointment, from which it perhaps differs in being less astringent. It forms a suitable dressing for recent *burns* of the first degree. The danger of poisoning by the absorption of the lead it contains is an objection to its prolonged use.

UNGUENTUM PLUMBI IODIDI, *U. S., Br.*—OINTMENT OF IODIDE OF LEAD.

Pomatum cum iodureto plumbico, *F. Cod.*; *Pommade d'iodure de plomb*, *Fr.*; *Jodbleisalbe*, *G.*

Preparation.—Iodide of Lead, in very fine powder, 10 parts (48 grains); Benzoinated Lard 90 parts (1 oz. av.); to make 100 parts (1 troyounce). Rub the iodide of lead with the benzoinated lard, gradually added, until they are thoroughly mixed.—*U. S., F. Cod.*

Iodide of lead, in fine powder, 62 grains; simple ointment 1 oz. av.; mix thoroughly.—*Br.*

Medical Uses.—The discutient influence of this ointment upon *enlarged glands* of the lymphatic system, and even upon certain *mammary tumors* of uncertain nature, is sometimes very distinctly marked. In chronic enlargement of the *testicle* following gonorrhœa it is often of palpable use. It has also been applied to some local *cutaneous eruptions*, but without demonstrable advantage.

UNGUENTUM POTASSÆ SULPHURATÆ, *Br.*—OINTMENT OF SULPHURATED POTASH.

Pommade de foie de soufre, *Fr.*; *Schwefellebersalbe*, *G.*

Preparation.—Take of Sulphurated Potash 30 grains; Hard Paraffin $\frac{1}{2}$ ounce; Soft Paraffin $\frac{1}{2}$ ounce. Triturate the sulphurated potash in a glass or porcelain mortar and gradually add the melted mixture of paraffins, rubbing them together until the ointment is perfectly smooth and free from grittiness. This ointment should be recently prepared.—*Br.*

Medical Uses.—Sulphurated potash ointment is only used in the treatment of *scabies*, for which it is an efficient remedy.

UNGUENTUM POTASSII IODIDI, *U. S., Br.*—OINTMENT OF IODIDE OF POTASSIUM.

Unguentum kalii iodati, *P. G.*; *Pomatum cum iodureto potassico*, *F. Cod.*—*Pommade d'iodure de potassium*, *Fr.*; *Jodkaliumsalse*, *G.*

Preparation.—Iodide of Potassium, in fine powder, 12 parts (60 grains); Hypsulphite of Sodium 1 part (5 grains); Boiling Water 6 parts (30 grains or 30 minims); Benzoinated Lard 81 parts (405 grains); to make 100 parts (500 grains). Dissolve the iodide of potassium and the hyposulphite of sodium in the boiling water in a warm mortar; then gradually add the benzoinated lard, and mix thoroughly.—*U. S.*

Iodide of potassium 64 grains; carbonate of potash 4 grains; distilled water 1 fluidrachm; benzoated lard 1 oz. av.—*Br.* Potassium iodide 10 parts, water 10 parts, benzoinated lard 80 parts.—*F. Cod.* Potassium iodide 20 parts, water 10 parts, paraffin ointment 170 parts.

The first formula is an adaptation of that of the *P. G.* 1872, the hyposulphite being increased from $\frac{1}{2}$ to 1 per cent. This addition is made for the purpose of preventing the liberation of free iodine and the gradual change of the color of the ointment from white to yellow and brown. Iodine added to this ointment will likewise be decolorized, with the formation of sodium iodide. (See *SODII HYPOSULPHIS*.) The addition of a little potassium carbonate, as directed by the *Br. P.* or of a few drops of potassa or soda solution, will likewise preserve the white color of the ointment.

Medical Uses.—The discutient powers of this ointment are certainly inferior to

those of the ointments of iodine; its only advantages consist in its being colorless and in not staining the linen. It is used to promote the reduction of *enlarged glands*.

UNGUENTUM STRAMONII, U. S.—STRAMONIUM OINTMENT.

Pommade de stramoine, Fr.; *Stechapfelsalbe*, G.

Preparation.—Extract of Stramonium 10 parts (48 grains); Water 5 parts (25 minims); Benzoinated Lard 85 parts (408 grains); to make 100 parts (1 troyounce). Rub the extract with the water until uniformly soft, then gradually add the benzoinated lard, and mix thoroughly.—*U. S.*

Medical Uses.—Stramonium ointment, although less efficient than belladonna ointment, may be used for the same purposes—viz. to allay *pain* and relieve *spasm*. It has been found to palliate the suffering caused by open *cancer* of the breast, and it affords much comfort in cancer of the *rectum*, *piles*, fissures of the *anus*, etc. An ointment composed of equal parts of stramonium ointment, ointment of galls, and cerate of subacetate of lead is very useful in these affections, and also to arrest the itching caused by vermicular *ascarides*.

UNGUENTUM SULPHURIS, U. S., Br.—SULPHUR OINTMENT.

Pomatum sulfuratum, F. Cod.; *Unguentum sulfuratum simplex*.—*Pommade soufrée*, Fr.; *Schwefelsalbe*, G.

Preparation.—Sublimed Sulphur 30 parts (1½ oz. av.); Benzoinated Lard 70 parts (3½ oz. av.); to make 100 parts (4 oz. av.). Rub the sulphur with the benzoinated lard, gradually added, until they are thoroughly mixed.—*U. S.*

Sublimed sulphur 1 ounce; benzoated lard 4 ounces.—*Br.* Washed sulphur 10 parts, almond oil 10 parts, benzoinated lard 80 parts.—*F. Cod.*

Allied Ointment.—UNGUENTUM SULFURATUM COMPOSITUM. Mix 1 part each of sublimed sulphur and powdered sulphate of zinc with 8 parts of lard.—*P. G.* 1872.

Medical Uses.—The chief use of sulphur ointment is in the treatment of *scabies*. The modes of using it and the conditions of its success have been described under SULPHUR.

UNGUENTUM SULPHURIS ALKALINUM, U. S.—ALKALINE SULPHUR OINTMENT.

Pomatum (Unguentum) antipsoricum, F. Cod.—*Pommade antipsorique*, P. d'Helmerich, Fr.; *Helmerich's Salbe*, G.

Preparation.—Washed Sulphur 20 parts (100 grains); Carbonate of Potassium 10 parts (50 grains); Water 5 parts (25 grains or minims); Benzoinated Lard 65 parts (325 grains = ¾ oz. av.); to make 100 parts (500 grains). Rub the sulphur with the carbonate of potassium and the water, gradually add the benzoinated lard, and mix thoroughly.—*U. S.*

Potassium carbonate 5 Gm., water 5 Gm., sulphur 10 Gm., expressed almond oil 5 Gm., lard 35 Gm. Mix in the order stated.—*F. Cod.*

Medical Uses.—The addition of potassium carbonate to sulphur ointment possesses no demonstrable advantage. Hebra says distinctly (*Sydenham Soc. ed.*, ii. 234), "Sulphur was found to be equally effectual, whether it was used alone or in combination with potassa, soda, or lime."

UNGUENTUM SULPHURIS IODIDI, Br.—OINTMENT OF IODIDE OF SULPHUR.

Pommade d'iodure de soufre, Fr.; *Jodschwefelsalbe*, G.

Preparation.—Take of Iodide of Sulphur 30 grains; Hard Paraffin ¼ oz.; Soft Paraffin ¾ oz. Triturate the iodide of sulphur in a glass or porcelain mortar, and gradually add the melted mixture of paraffins, rubbing them together until the ointment is perfectly smooth and free from grittiness.—*Br.*

Medical Uses.—Its tendency to speedy decomposition renders this ointment practically of little value, even in the treatment of limited chronic eruptions of *eczema*, *lepra*, and *acne*, and of *lupus*.

UNGUENTUM TEREBINTHINÆ, Br., P. G.—OINTMENT OF TURPENTINE.

Onguent térébenthiné, Fr.; *Terpenthinsalbe*, G.

Preparation.—Take of Oil of Turpentine 1 fluidounce; Resin, in coarse powder, 54 grains; Yellow Wax, Prepared Lard, each $\frac{1}{2}$ ounce. Melt these ingredients together by the heat of a steam- or water-bath. Remove the vessel, and stir the mixture constantly while it cools.—*Br.*

Melt turpentine and yellow wax, of each 1 part, and add oil of turpentine 1 part.—*P. G.*

UNGUENTUM DIGESTIVUM SIMPLEX, *F. Cod.*—Onguent digestif simple. *Fr.*—Triturate Venice turpentine 40 parts with yolk of egg 20 parts, and add olive oil 10 parts.

Medical Uses.—This ointment has the same virtues as the compound resin cerate, but, being softer, is more convenient for application to *burns*, *erysipelas*, *erythema*, and other recent local inflammations of the skin.

UNGUENTUM VERATRINÆ, U. S., Br.—VERATRINE OINTMENT.

Unguentum veratriæ, U. S. 1870, Br.—*Veratria ointment*, F.; *Pommade de vératrine*, Fr.; *Veratrinsalbe*, G.

Preparation.—Veratrine 4 parts (20 grains); Alcohol 6 parts (30 grains or 40 minims); Benzoinated Lard 96 parts (480 grains). Rub the veratrine with the alcohol in a warm mortar until dissolved; then gradually add the benzoinated lard, and mix thoroughly.—*U. S.*

Rub together veratrine 8 grains and olive oil 1 fluidrachm; melt hard paraffin $\frac{1}{2}$ ounce and soft paraffin $\frac{3}{4}$ ounce, and mix the whole thoroughly in a mortar until cold.—*Br.*

To prevent annoyance from the dust arising during the trituration of dry veratrine, the alkaloid should be previously covered with a small quantity of olive oil or thoroughly dampened with a little alcohol; the first formula directs it even to be dissolved in alcohol, the solvent evaporating on the continued trituration in a warm mortar.

Medical Uses.—The American is more than twice as strong as the British ointment. (For an account of its uses see VERATRINA.)

UNGUENTUM ZINCI OXIDI, U. S.—OINTMENT OF OXIDE OF ZINC.

Unguentum zinci, Br., P. G.; *Unguentum de nihilo albo*.—*Pommade d'oxyde de zinc*, Fr.; *Zinksalbe*, G.

Preparation.—Oxide of Zinc 20 parts (100 grains); Benzoinated Lard 80 parts (400 grains); to make 100 parts (500 grains). Rub the oxide of zinc with 20 parts (100 grains) of benzoinated lard, previously melted, until the mixture is perfectly smooth; then add the remainder of the benzoinated lard, and mix thoroughly.—*U. S.*

Other pharmacopœias direct: Oxide of zinc 80 grains, benzoinated lard 1 oz. av.—*Br.* Oxide of zinc 1 part, benzoinated lard (lard, *P. G.*) 9 parts.—*F. Cod.*

The Pharmacopœia has partially adopted a suggestion made in previous editions of this work, but instead of directing the benzoinated lard to be previously melted, it would have been more to the point to simply order the use of a hot mortar; for the oxide of zinc is readily obtained in an impalpable powder, and is uniformly diffused through the ointment by trituration; it well in a warm mortar with about its own weight of benzoinated lard until the mixture is perfectly smooth, when the remainder of the lard may be added. Glycerin or expressed almond oil may also be used in sufficient quantity for forming a soft paste. On keeping, the ointment gradually acquires a tough consistence.

Allied Preparations.—UNGUENTUM ZINCI OLEATI, *Br.* Oleate of zinc 1 oz.; soft paraffin 1 oz. UNGUENTUM CALAMINÆ, *Br.* (Turner's cerate). Prepared calamine 1 oz.; benzoated lard 5 oz. CERATUM ZINCI CARBONATIS, *U. S.* 1870. Precipitated zinc carbonate 1 oz.; simple ointment 5 oz.

Medical Uses.—Oxide of zinc ointment is a protective, astringent, and mildly stimulant application, adapted to *ulcers* which are irritable, have loose granulations, and discharge pus copiously. It is especially useful as a dressing for *fissures* of the nipple and anus; for local eruptions of *eczema*, *herpes*, and *impetigo*; for all cases of simple *abrasion* or *ulceration*, including blistered surfaces, after their active inflammation has subsided; for *ophthalmia tarsi*, etc. The cerate, which is no longer officinal, was employed in similar affections.

UREA.—UREA.

Carbamid.—*Urée*, Fr.; *Harnstoff*, G.

Formula $\text{CH}_4\text{N}_2\text{O} = \text{CO}(\text{NH}_2)_2$. Molecular weight 60.

Origin.—Urea was discovered in urine by Rouelle (1773), and, in the impure condition in which he obtained it, designated as *extrait savonneux de l'urine*. Foureroy and Vauquelin (1799) prepared it in the pure state. It has been found in the urine of mammals, more particularly in that of the Carnivora, in the urine of birds and other animals, and in many animal fluids. Human urine contains from 2 to 4 per cent. of urea. The transformation into urea of ammonium cyanate by evaporating its aqueous solution, as observed by Wöhler (1828), was the first instance in which an organic compound produced in the living organism was artificially formed. Urea has also been artificially prepared from other cyanogen compounds.

Preparation.—Urine is evaporated to a syrupy consistence, allowed to cool, and the residue mixed with an equal volume of nitric acid. The nitrate of urea, which crystallizes in scales and prisms, is purified by washing with cold water and by recrystallization, and is then decomposed by boiling with water and barium carbonate; the filtrate is evaporated and the residue exhausted with alcohol. Oxalic acid and calcium carbonate may be substituted in this process for nitric acid and barium carbonate.

Properties.—Urea crystallizes in colorless and inodorous four-sided prisms, which have a cooling saline taste and are permanent in dry air. It melts near 120°C . (248°F .), and at a higher heat is decomposed, giving off ammonia and leaving cyanuric acid, which at a still higher temperature yields cyanic acid. Urea dissolves in its own weight of cold water, is readily soluble in alcohol, but is slightly soluble in pure ether. In contact with nitrous acid urea is decomposed into carbonic acid, nitrogen, and water. A similar decomposition is effected by an acidulated solution of permanganate of potassium. Dissolved in pure water, urea keeps unchanged for a long time, but in the presence of putrefiable matter it is rapidly decomposed, yielding ammonia and carbonic acid; hence, foul urine contains no urea.

Urea forms crystallizable compounds with acids, with metallic oxides, and with many neutral salts. *Hydrochlorate of urea* is very deliquescent. *Nitrate of urea*, $\text{CH}_4\text{N}_2\text{O} \cdot \text{HNO}_3$, is slightly soluble in cold water and alcohol and nearly insoluble in nitric acid; it contains 48.78 per cent. of urea. *Oxalate of urea*, $(\text{CH}_4\text{N}_2\text{O})_2 \cdot \text{H}_2\text{C}_2\text{O}_4$, crystallizes in scales which dissolve at 15°C . (59°F .) in 23 parts of water, but require a much larger quantity of solution of oxalic acid; it contains 57.14 per cent. of urea. The amount of urea in urine is frequently determined by forming the compound either with nitric or oxalic acid.

Allied Compound.—**FORMAMID**, $\text{CH}_3\text{NO} = \text{CHO} \cdot \text{NH}_2$. It is produced on the dry distillation of ammonium formate on heating a mixture of this salt and of urea to about 140°C . (284°F .), on heating ethylformate and ammonia, and by various other processes. It is a colorless oily liquid, which in vacuo distils without decomposition below 150°C . (302°F .), and which is soluble in water and alcohol in all proportions, but is insoluble in ether. **MERCURIC FORMAMID**, *Hydragryum formamidatum*, has been used hypodermically.

Medical Action and Uses.—Half a century ago it was demonstrated by Ségalas that urea injected into the veins of animals increased notably the discharge of urine, with a greatly augmented proportion of urea, and, much more recently, Wöhler and Frerichs alleged that when introduced into an animal's stomach it reappeared almost entirely in the urine. Gallois, however, proved that only two-thirds at most of the urea thus administered was recoverable from the urine, and also that in very large doses, such as 300 grains, given to a rabbit, it occasioned prostration, trembling, convulsions, and death. Similar large doses injected into the veins or hypodermically produced the same effects, and non-lethal quantities of urea occasioned deep coma, paroxysmal spasms, hurried respiration, trembling, injection of the capillary vessels, and frequent urination.

Although, according to Rabuteau, it exhibits no diuretic action in man, even when taken to the extent of 75 grains (Gm. 5) a day, yet several physicians have testified to its virtues in *dropsy*, and one of high reputation particularly recommended the nitrate of urea as a remedy for scarlatinous dropsy. It was prescribed in doses of 2 or 3 grains (Gm. 0.12–0.18) several times a day. In the last edition of this work it was stated that this medicine is probably now quite obsolete, and should be consigned to the "*Dreckapotheke*," as Strumpf long ago suggested. But more recently we are assured by a Russian physician that *carbamid* may be used as a substitute for quinine. According to him, it

is an apyretic, and yet does not depress the nervous system. He asserts that in Southern Russia the peasants cure themselves of intermittent fever by drinking their urine (*Med. News*, xlii. 215).

URTICA.—NETTLE.

Ortie brûlante, Fr.; *Brennessel*, G.

Urtica dioica, Linné, and *U. urens*, Linné.

Nat. Ord.—Urticaceae, Urticeae.

Origin and Description.—Both plants are common in waste places, along hedges and roadsides, throughout the greater part of Europe and Northern Asia, and have been thoroughly naturalized in North America, where the small annual, *U. urens*, is less frequent than the taller perennial, *U. dioica*. Both species are covered with stiff stinging hairs and have opposite stipulate and petiolate leaves.

URTICA DIOICA. The leaves are 2 or 3 inches (5–8 Cm.) long, dark-green above, whitish downy beneath, ovate or ovate-lanceolate, heart-shaped, pointed, and coarsely serrate. The small greenish flowers are usually dioecious, in small clusters, and these are arranged in branching and hanging spikes. The bast-fibres have been used for the manufacture of *nettle-cloth*.

URTICA URENS. The leaves are 1 or 2 inches (2–5 Cm.) long, pale-green, elliptic, deeply serrate, and almost five-nerved. The small and loose flower-clusters appear in axillary pairs.

Allied Plants.—URTICA (*Laportea*, *Gaudichaud*) *CANADENSIS*, Linné. The leaves are alternate, 4 to 6 inches (10–15 Cm.) long, long-petioled, ovate or elliptic, obtusely serrate, and strongly feather-veined. The flower-clusters form axillary loosely-paniculate cymes. The plant is common in miry, shaded grounds, attains a height of 3 to 5 feet (.9–1.5 M.), is armed with stinging hairs, and has strong bast-fibres.

URTICA *CRENULATA*, *Roxburgh*, *U. STIMULANS*, Linné, and *U. URENTISSIMA*, *Blume*, are more violently irritating than the above species; they are indigenous to India and to the East Indian islands.

U. PILULIFERA, Linné, grows in India, Central Asia, and in Southern Europe. The fruit is a roundish and flat akene, glossy, gray-brown, somewhat resembles flaxseed, but is smaller, and has an oily, mucilaginous, and slightly acrid taste: it is used in Oriental countries as a galactagogue. The root is regarded as diuretic.

The bast-fibres of several nettles in addition to those mentioned above are valuable for cordage and woven fabrics. *Urtica cannabina*, Linné, is cultivated in Siberia. *Bœhmeria nivea*, *Hooker et Arnott*, of Eastern Asia, yields the *ramie* fibre, from which *China grass-cloth* is made. The variety *candicans*, *Weddell* (*B. tenacissima*, *Gaudichaud*) yields the *rhea* fibre. The fabrics often possess considerable brilliancy, and these fibres are used as a substitute for, or are mixed with, silk.

Constituents.—The analyses of the fresh nettle by Saladin (1830) and by Böhlig (1840) proved the presence of mucilage, salts, and other common constituents of plants, and on distilling the herb with water notable quantities of ammonia and carbonic acid were found in the distillate. B. Shoemaker (1866) observed that the watery distillate from the root had diuretic properties. Gorup-Besanez (1849) recognized the irritating compound contained in the stinging hairs as free *formic acid*, which is also contained in the aqueous distillate of the fresh herb. A. Buchner, however, observed that the inflammation produced by free formic acid is of a different character from that produced by nettles, and regarded the presence of another irritating compound besides formic acid as probable.

Medical Action and Uses.—The seeds and leaves of the nettle were much used in ancient times in poultices or bruised for unhealthy ulcers as well as for recent wounds and sprains. The bruised leaves were introduced into the nostrils to arrest epistaxis, and given in honey for the cure of pulmonary catarrhs. The well-known irritation of the skin caused by nettles is due to an acrid secretion contained in a minute vesicle situated at the base of each of the stiff hairs that beset the leaves. When the points of these sharp and hollow spines penetrate the skin, the poisonous juice is expressed into its tissue, and gives rise to a burning and stinging pain, with inflammatory redness and swelling. The case is recorded of a woman who, by mistake, drank 2 cupfuls of a decoction of nettle-leaves. On the following day she experienced severe burning over the whole of the upper part of the body, with formication and stiffness. The features were greatly swollen. Over the affected surface minute vesicles appeared, which burst and discharged a limpid and in some parts a bloody fluid. In the course of five or six days the eruption dried up. No fever accompanied the attack (*Archives gén.*, 1835).

Nettle-juice has always been reputed to be an efficient remedy for spontaneous hæmorrhage of nearly every variety, including *hæmoptysis*, *menorrhagia*, *post-partum hæmorrhage*, and *epistaxis*. Allowing for the difficulty of determining the efficacy of any medicine in arresting hæmorrhage, there appears to remain so great a preponderance of evidence in favor of the one under consideration as to render scepticism in regard to it unreasonable, especially as in most of the cases numerous hæmostatics of recognized activity had failed before this medicine was employed. The juice was administered in doses of half an ounce or an ounce at intervals of several hours, and in no case does it appear to have given rise to any disagreeable or untoward effects. This preparation is also reported to have been very efficacious in certain cases of *gravel*, *jaundice*, and *dropsy*, and the seeds have been used in *diarrhœa*, *dysentery*, *leucorrhœa*, and nocturnal *incontinence of urine*. The decoction of the leaves and stalks is also said to display curative powers in chronic *diseases of the skin*, and, as well as the expressed juice, to cure ulcerative affections of the mouth and throat. Poultices made by boiling the fresh leaves have been reputed to cure gangrenous, scorbutic, and other unhealthy *ulcers*. Urtication is the name applied to producing an irritation of the skin by means of nettles. It is performed by taking in the gloved hand a bunch of nettles and flagellating the skin with it until the redness and the stinging pain denote that the intended effect is produced. This peculiar stimulant revulsion and counter-irritation has been long employed for arousing to consciousness persons affected with *lethargy*, *congestion of the brain*, *intoxication by alcohol* or *opium*, or *hysterical insensibility*. It has also been used upon the loins and thighs to cure *amenorrhœa* and *sexual impotence*, and, above all, as a means of restoring power to *paralyzed limbs*. The advantages it presents over blistering, pustulation by croton oil, etc. consist in the vivid and intense impression it produces, and which likens it to electricity and massage. It seems to be a rude expedient, but cases may occur, particularly in the country, for which it would be peculiarly adapted.

In Germany the dried young shoots are used in a decoction made with from 10 to 20 parts to 100 parts of water. The juice of the fresh plant is given internally in tablespoonful doses.

USTILAGO, U. S.—USTILAGO.

Cornsmut, *Corn-ergot*, E.; *Maisbrand*, *Beulenbrand*, G.

Ustilago (Uredo, *De Candolle*) Maydis, *Leveillé*.

Nat. Ord.—Fungi, Ustilagineæ.

Origin.—The numerous species of the genus *Ustilago* grow upon living plants, the tissue of which is penetrated by the mycelium. The spores are produced in the hyphæ or their branches, which gradually form a gelatinous mass, and this is subsequently resorbed, so that finally the isolated spores remain behind. These are of a black or brown color, consist of a single cell, and have the outer membrane or exosporium either smooth or variously marked. The species mentioned above lives upon maize (*Zea Mays*, *Linne*, nat. ord. Graminacæ), attacks the vegetative and reproductive organs, and in the latter often attains a considerable size.

Description.—Cornsmut forms irregular globose masses, which are somewhat lobed or obtusely branched, and sometimes 6 inches (15 Cm.) or more thick. The smooth or gelatinous membrane forming the covering of the fungus is diaphanous, and shows a blackish tint from the enclosed spores. Enclosed by this membrane is found a blackish-brown or brownish-black powder, consisting of innumerable spores, which are globular or oval, and when observed under the microscope have a nodular or spiny appearance, from the projections of the exosporium. Cornsmut has a peculiar rather heavy odor and an unpleasant taste. It should be preserved in a dry place, and should be kept on hand not longer than a year. *Ustilago segetum*, *Dittmar* (U. Carbo, *Tulasne*), which attacks oat, barley, wheat, and other grasses, has somewhat smaller globular spores, which are smooth.

Constituents.—C. H. Cressler (1881) showed the presence of a volatile base, which is probably identical with *trimethylamine*, and a sugar which crystallizes in needles, is very sweet, and does not reduce Trommer's test solution; it is probably *mycose*; fixed oil, resin, and gummy matter were likewise obtained. Examined by J. H. Hahn (1881) and H. B. Parsons (1882), air-dry cornsmut yielded 9 to 10 per cent. of moisture, 2.5 to 4.2 per cent. of ether extract, and 4 to 5.5 per cent. of ash. Alcohol takes up about 10 per cent., and water about 6.6 per cent., of soluble matter, from the latter of which Prof. Parsons obtained 5.5 per cent. of an acid compound which is probably identical with sclerotic acid, and is prepared by the same process (see p. 580).

Medical Action and Uses.—It appears that several other cereals are subject to

diseases which form products resembling ergot in their action. In 1870, Haselbach related that on several occasions cows had calved prematurely from having eaten maize affected with smut (Husemann, *Arch. f. Pathol. u. Pharmacol.*, ix. 276). In 1877, Estachy published the note of a case in which he successfully made use of smutted maize to revive suspended labor-pains. Afterward he employed it successfully in the treatment of *hæmoptysis*, *seminal pollutions*, and *post-partum hæmorrhage* (*Bull. de thérap.*, xciv. 85). It may be questioned whether such facts justify granting an official rank to this product. From a series of experiments with it, Dr. James Mitchell (*Inaug. Thesis*, Univ. of Penna., 1883) concluded that it destroys consciousness, paralyzes first the sensory portion of the spinal cord, and, after depressing, paralyzes also the motor centres of the cord and motor nerves, and that probably the sensory nerves share in the general paralysis.

The *stigmata* of maize, or "corn silk," have for a long time had a popular reputation in the south of France as a remedy for *strangury* and *calculous affections*, and they have also been held to possess anodyne virtues (*Bull. de thérap.*, xcvi. 377). In 1879, Dufau described this product as actively *diuretic* in cardiac and renal *dropsy*, and stated that the best effects followed its use in cases of *uric* and *phosphatic gravel*, *pyelitis*, *retention* and *incontinence of urine*, and *vesical catarrh* (*Med. Record*, xvi. 252). These statements have been confirmed and extended by various others, including Landrieux, who insists strongly on the diuretic action of the medicine (*Practitioner*, xxiv. 453; xxv. 379), Busey (*Med. Record*, xix. 319), Ducasse (*Amer. Jour. of Med. Sci.*, April, 1883, p. 565), and Stüver (*Med. News*, xliii. 372). According to Vauthier, maizenic acid is the active principle of the stigmata. It is recommended to be given in *doses* of $\frac{1}{2}$ grain. An extract of the stigmata has been given in syrup to the extent of 20 or 30 grains (Gm. 1.30-2) a day.

Dupont particularly insists on the efficacy of the medicine in *cardiac dropsy* and in obstructive valvular disease of the heart (*Gaz. med. de Paris*, No. 9, 1884).

UVÆ, Br.—RAISINS.

Uva passa, U. S. 1870; *Passulæ*.—*Raisins*, Fr.; *Rosinen*, Zibeben, G.

The dried fruit of *Vitis vinifera*, Linné. Bentley and Trimen, *Med. Plants*, 66.
Nat. Ord.—Vitaceæ.

Origin.—The *Vitis vinifera* is indigenous to Western Asia and probably to Northern Africa, and has been cultivated in Europe from a very early period; it has been introduced into North America, chiefly on the Pacific coast, and into other temperate countries. A large number of varieties have been produced, differing in the shape, size, and color of their berries and in other characters. Some botanists refer the different varieties of grapevine to three or four species. The *Catawba*, *Isabella*, *Concord*, and other grapes usually cultivated in the United States, are varieties of the indigenous *Vitis Labrusca*, Linné.

The genus *Vitis* consists of shrubs climbing by tendrils, and bearing these and the greenish, compound-racemose flowers opposite the leaves. The calyx is small, the five petals are united at the apex, fall off together by separating at the base, and alternate with five stamens, which enclose a two-celled ovary, ripening into a juicy berry containing about four hard pyriform seeds.

The tender branchlets (*pampini vitis*) with the leaves are sometimes employed for their agreeable acidulous flavor. The unripe berries (*agresta*) contain a considerable amount of tartaric acid, and yield, when expressed, a very acerb juice (*omphacium*), which after fermentation is *suc de verjus*, F. Cod. The mature fruits, dried, constitute the raisins.

Collection.—When the grapes are ripe their stalks are cut half through or a portion of the bark is removed, and the grapes are allowed to remain upon the vines for a few weeks, and then cut off, sometimes steeped for a short time in a weak lye to remove the waxy bloom, and then completely dried; or the ripe grapes are cut off, spread out upon a hard clay floor, and dried by exposure to the sun, which requires a week or two. In rainy weather artificial heat is used for drying them.

Description.—The ripe berry of the grapevine is one-celled from the obliteration of the cell-wall, and is globular or oblong in shape. After drying it is shrivelled and flattened, more or less orbicular, of a brownish color, and somewhat translucent. When long kept, raisins become more opaque, owing to the crystallization of the sugar and cream of tartar. Raisins are produced in Southern Europe, and in commerce are distinguished generally by the ports of exportation.

Varieties.—*UVA MALACENSES*, *F. Cod.*, *Passulæ majores*.—Raisins de Malaga, *Fr.*—Those produced in Spain are usually preferred, and are ordered by the *Br. P.* They have either been removed from the stalks, like the *Valencia raisins*, or are sold in bunches, like the *Malaga* or *Muscadel raisins*. The *seedless* or *Sultana raisins* are rather smaller than the Spanish and Italian raisins, and are exported from Asia Minor.

UVA CORINTHIACÆ, *F. Cod.*, *Passulæ minores*.—Corinthian raisins, *E.*; Raisins de Corinth, *Fr.*; Korinthen, *G.*—They are produced in Greece and the adjacent islands, and are often incorrectly called *currants*; they are much smaller than those previously described, are usually deprived of their stalks, mostly adhere together in masses, and have a vinous odor and a sweet and acidulous taste.

Constituents.—The *skin* of ripe grapes contains tannin and coloring matter. The chief constituents of the *pulp* are grape-sugar and acid tartrate of potassium, besides gummy matter, calcium tartrate, and a small quantity of malic acid. The *seeds* contain about 5 per cent. of tannin, green resin, and over 10 per cent. of a bland oil (see p. 1065).

Off. Prep.—*Tinct. cardamomi comp.*, *Tinct. sennæ*, *Br.*

Medical Uses.—The pulp of raisins is nutritive and demulcent, and is used to flavor mucilaginous and amylaceous infusions, such as those of flaxseed, oatmeal, rice, barley, etc.

UVA URSI, U. S., *F. Cod.*—*UVA URSI*.

Uva ursi folia, *Br.*, *P. G.*—Bearberry-leaves, *E.*; *Busserole*, *Raisin d'ours*, *Fr.*; *Bärentraubenblätter*, *G.*

The dried leaves of *Arctostaphylos* (*Arbutus*, *Limé*) *Uva ursi*, *Sprengel* (*Arct. officinalis*, *Wimmer*). *Woodville, Med. Bot.*, plate 70; *Bentley and Trimen, Med. Plants*, 163. *Nat. Ord.*—*Ericaceæ*, *Ericineæ*.

Origin.—The bearberry is a trailing, much-branched, evergreen shrub, which is distributed throughout the northern portion of the northern hemisphere, and grows in most parts of Europe, in Northern Asia, and throughout the North American continent as far south as New Jersey and in the mountains of Colorado. It is found in dry, rocky, or sandy places and in pine woods; southward it grows chiefly in hilly or mountainous regions. It bears short and drooping racemes of from three to twelve whitish, urn-shaped flowers and small, bright-red drupes containing five flattened nutlets, each with one seed. The flowers appear in May, and the fruit ripens in autumn, at which time the leaves should be collected.

Description.—Bearberry-leaves are nearly sessile, about $\frac{4}{5}$ inch (2 Cm.) long, $\frac{1}{4}$ or $\frac{1}{2}$ inch (6–8 Mm.) wide, obovate or oblong-spatulate, entire, and slightly revolute on the margin, obtuse or apparently retuse at the apex, and almost wedge-shaped at the base. They have a leathery texture, a dark-green rather glossy upper surface, with depressed veins, are paler, smooth, and reticulately-veined beneath, and the leaves have a faint hay-like odor and a strongly astringent and slightly bitter taste.

Constituents.—Meissner (1824) found in *uva ursi* gallic acid and tannin, producing with ferric salts a blue-black precipitate. Kavalier (1852) corroborated the existence of gallic acid in bearberry-leaves, and to its presence is due the red and violet color produced by a fragment of ferrous sulphate when agitated with an infusion made from 1 part of *uva ursi* with 50 parts of water. Bowman (1869) determined the amount of tannin, by means of gelatin, to be 6.33 per cent. Besides resin, sugar, and some other unimportant constituents, Kavalier isolated from the leaves arbutin and ericolin, and Trommsdorff another crystalline body, ursone. *Arbutin*, $C_{12}H_{22}O_{14} \cdot H_2O$, is obtained from the decoction of the leaves by precipitating it with subacetate of lead, treating the filtrate with sulphuretted hydrogen, and evaporating to crystallize. It forms neutral, colorless, silky needles, of a bitter taste, freely soluble in hot water and in alcohol.

FIG. 302.

Arctostaphylos Uva ursi, *Sprengel*.

and sparingly soluble in ether. Julius Jungmann (1872) observed that an aqueous solution of arbutin, rendered alkaline by ammonia or potassa, acquires a deep azure-blue color on the addition of phosphomolybdic acid. On being dissolved in strong nitric acid, arbutin yields, after the addition of alcohol, pale-yellow needles of *nitro-arbutin*. By emulsin or by hot diluted sulphuric acid arbutin is decomposed into glucose and *hydrokinone* or *arctwin*, $C_6H_6O_2$, and *methylhydrokinone*, $C_7H_8O_2$. Hydrokinone crystallizes in colorless, fusible, and sublimable prisms, is easily soluble in water, alcohol, and ether, and is also produced from kinic acid by destructive distillation. On oxidizing hydrokinone or arbutin with binoxide of manganese and sulphuric acid *kinone* is formed (see page 466). Hughes' *ursin* (1847) was proven by Jungmann to be impure arbutin.

The mother-liquor from the preparation of arbutin contains *ericolin* (see page 876). After washing the alcoholic extract of bearberry-leaves with water and ether, boiling alcohol extracts from the residue *ursone*, $C_{20}H_{34}O_2$; this crystallizes in tasteless, silky, fusible, and sublimable needles, is insoluble in water, dilute acids, and alkalis, and is sparingly soluble in ether and cold alcohol.

Arbutin, ericolin, and ursone have been obtained also from the leathery leaves of other Ericaceous plants.

Adulterations and Substitutions.—The leaves of the following plants are said to have been sometimes mistaken for those of *uva ursi*:

Vaccinium vitis-idaea, Linné. It is known as *cowberry*, and grows from New England northward and in Europe. The leaves resemble those of *uva ursi*, but are not reticulate, and on the lower surface are dotted with fine, blackish, bristly points.

Vaccinium uliginosum, Linné. This is known as *bog-hilberry*, and grows in Europe and the northern part of North America. The leaves are scarcely leathery, and are pale blue-green and pubescent on the lower surface; otherwise they resemble the leaves of *uva ursi*.

Leiophyllum buxifolium, Elliott. The *sand-myrtle*, indigenous to the United States from New Jersey southward, is a small shrub about 6 inches (15 Cm.) high. Its leaves are about $\frac{3}{4}$ inch (8 Mm.) long, oval or oblong, shining, reticulate, and revolute on the margin.

Buxus sempervirens, Linné. The *box*, commonly cultivated in gardens, has ovate leaves, which are narrower towards the apex than near the base. The leaves contain tannin (Buchner), butyricaceous volatile oil, bitter extractive, etc. (Bley, 1834); the bitter taste is due to *buxine* and *parabuxine*. (See NECTANDRA and PAREIRA BRAVA.)

Allied Species.—*Arctostaphylos glauca*, Lindley. This shrub or small tree grows in dry and rocky localities on the western slope of the Sierras in California, where it is known as *manzanita*. The leaves are about 2 inches (5 Cm.) long, coriaceous, ovate-oblong, acute above and rounded or obtuse at the base, entire on the margin, and of a pale-green color. It was examined by J. H. Flint (1873), and found to contain arbutin, 9.8 per cent. of tannin, and 6 per cent. of ash. The leaves are employed like *uva ursi*.

Off. Prep.—*Extr. uvæ ursi fluid.*, U. S.; *Infus. uvæ ursi*, Br.

Medical Action and Uses.—*Uva ursi*, or bearberry, in small doses appears to promote the appetite and confine the bowels, but in large quantities it occasions vomiting and purging, rendering it probable that its medicinal effects do not depend solely upon its astringent principles. On the healthy system it does not produce any diuretic action, but in calculous affections the urine sometimes seems to augment under its influence. It gives to this secretion a dark color and a peculiar odor.

Uva ursi appears to have been first used by physicians about the middle of the eighteenth century. It was then employed in calculous affections and in all chronic disorders of the urinary passages, from the kidneys to the urethra. It has proved useful in chronic *pyelitis* and *cystitis*, and even in calculous forms of those affections, probably by constringing the mucous membrane of the kidneys and bladder, diminishing its vascularity, and thereby obtunding its sensibility. In many cases, as a consequence of this mode of action, it has caused the parts affected to become more or less insensible to the mechanical irritation of the concretions enclosed by them, and thereby lessened the impediment to the passage of the urine. In this manner, no doubt, it often relieves *incontinence of urine*, *dysury*, and *strangury*. So complete is the relief sometimes afforded by it that a notion once gained credit of its being a solvent of *urinary calculi*. But in truth its mode of action is in great part like that of lime-water, whose efficacy under analogous circumstances is well known: it renders the mucous membrane of the urinary passages less susceptible to mechanical irritation. The benefits of the medicine in most of the cases referred to are only to be obtained by its persistent use. But in strangury from blisters its action is sometimes very prompt. *Uva ursi* has been also used with advantage for chronic *bronchitis* and atonic *diarrhœa*, *leucorrhœa*, and *hæmorrhage*, especially uterine hæmorrhage. It is alleged to act as an *oxytocic*. Arbutin is alleged to be an efficient diuretic in *cardiac dropsy*, and it has also been prescribed with alleged advantage in

urethritis. It may be given in large doses without any ill effect. As a diuretic it has been given in doses of about 12 grains (Gm. 1) per diem, mixed with powdered sugar; and also in a 5 per cent. watery solution.

The dose of the drug in powder is generally stated to be from 20 to 60 grains (Gm. 1.30-4), but its most striking effects have been obtained by doses not greater than a fourth of that just mentioned. The decoction, infusion, and fluid extract of *uva ursi* are efficient; the last is official.

Buxus sempervirens was found by Ringer and Murrell to produce tetanus, followed by paralysis, in frogs (*Med. Chir. Trans.*, lix, 389).

VALERIANA, U. S.—VALERIAN.

Valerianæ rhizoma, Br.; *Radix valerianæ*, P. G.; *Radix valerianæ minoris*.—*Valerian-root*, E.; *Valériane officinale*, Fr.; *Baldrianwurzel*, G.

The root of *Valeriana officinalis*, *Linné*. Woodville, *Med. Bot.*, plate 96; Bentley and Trimen, *Med. Plants*, 146.

Nat. Ord.—Valerianaceæ.

Origin.—Valerian is a native of Europe from the Mediterranean northward, and of Northern Asia, and is cultivated to some extent in Holland and England, and in this country in New England and New York. It is an herbaceous perennial, and grows on the banks of streams and other wet places, and likewise in uplands and dry situations. It varies considerably in size and in foliage, and several of the varieties have been regarded by some botanists as distinct species. The plant is easily propagated from short horizontal runners. It is 2 to 4 feet (.6-1.2 M.) high, branching at the top, has opposite, clasping, long-petiolate and oddly pinnate leaves, with from four to ten pairs of oval or lance-linear, entire or toothed, sessile, and smooth leaflets, and bears compound cymes composed of numerous small pinkish, triandrous flowers. The fruit is an ovoid, compressed akene, crowned by a plumous pappus. The rhizome with the rootlets attached constitute the official portion, and is collected in autumn.

Description.—The rhizome of valerian is upright, subglobular or obconical, truncate below, and at the apex often crowned with short portions of the overground stem or with a tuft of short leaf-bases, and indistinctly marked with closely approximate leaf-scars. It varies in length between about $\frac{1}{2}$ and $1\frac{1}{4}$ inches (1-3 Cm.), has a diameter nearly of the same dimensions, and is on all sides furnished with numerous slender nearly cylindrical rootlets. These are from 2 to 6 inches (5-15 Cm.) long, about $\frac{1}{8}$ inch (3 Mm.) thick at the base, simple, except near the tip, where they are divided into numerous fine fibres, which are rarely present in the commercial drug. A few short stolons, with long internodes, are occasionally attached to the rhizome. The rhizomes collected from dry situations are the smallest, have a light yellowish-brown color, are subglobular in shape, have a comparatively large number of rather short, thin, and light-colored rootlets attached, and are preferred for medicinal purposes on account of the larger proportion of volatile oil contained in them. The rhizomes collected in wet localities are more elongated, of larger dimensions, more fleshy and hygroscopic, and are therefore frequently cut longitudinally to facilitate their drying; they are darker in color, near the lower end marked by scars from decayed rootlets, and near the middle and upper portion have longer, thicker, and darker-colored rootlets than the preceding variety, attaining a length of 10 or 12 inches (25-30 Cm.). The rootlets of valerian are rather brittle and break with a short fracture; the rhizome is tougher, and in the interior rather horny and of a light grayish-brown color. It has a thin bark, which by a dark cambium-line is separated from a narrow circle of whitish woody tissue, and this encloses a large central pith. The rootlets have a thick bark surrounding a slender ligneous cord. Under the microscope the parenchyma is seen to contain cells filled with starch, extractive matter, and oil or resin. The recent rhizome has a very slight odor, but on drying a peculiar somewhat camphoraceous and terebinthinate odor appears, which on long keeping gradually changes to a strong somewhat cheese-like odor. The taste of valerian is at first sweetish, afterward unpleasant, cam-

phoraceous, and somewhat bitter. The rootlets of the commercial drug sometimes cover a large amount of dirt.

Constituents.—The most important constituent of valerian is its volatile oil (see page 1100), which varies in proportion between about $\frac{1}{4}$ and 2 per cent., the fresh rhizome from dry soil yielding the larger amount. Cultivated valerian seems to be less rich in volatile oil. Recent valerian on being distilled with water yields a distillate which, according to Schoonbroodt (1868), is neutral or nearly so. Free valerianic acid does not exist in fresh valerian, but is generated from the volatile oil on exposure. The relative proportions of the volatile oil and valerianic acid must therefore vary with the age of the drug. Aschoff (1846) found in the root also malic, acetic, and formic acids. The constituents which are of less medicinal importance are tannin, extractive, sugar, starch, mucilage, resin, etc.

Admixtures.—Although valerian is readily distinguished from other medicinal roots, it has been sometimes observed sophisticated with poisonous drugs somewhat resembling valerian in appearance, and from contact with the latter having acquired to some extent its peculiar odor. *Cynanchum Vincetoxicum* (p. 537) was noticed by Charbonnier (1877). *Veratrum album* (see below) by Holmes (1877), and *Sium latifolium* (p. 452) by Bernbeck (1880).

Pharmaceutical Preparations.—**AQUA VALERIANÆ.** Distil 1 part of bruised valerian with sufficient water to obtain 4 parts of distillate.—*F. Cod.*

SYRUPUS VALERIANÆ. Extract of valerian 4 Gm., valerian-water 100 Gm., sugar 180 Gm.—*F. Cod.*

SPIRITUS ANGELICÆ COMPOSITUS. Valerian 4 parts, juniper-berries 4 parts, angelica 16 parts, alcohol 75 parts, and water 125 parts; distil 100 parts, and dissolve in the distillate camphor 2 parts.—*P. G.*

Off. Prep.—*Abstractum valerianæ*, *Extr. valerianæ fluid.*, *U. S.*; *Infusum valerianæ*, *Br.*; *Tinct. valerianæ*, *Tinct. valerianæ ammoniata*, *U. S.*, *Br.*

Allied Drugs.—*Valeriana Phu*, *Linne*, is a tall perennial of Western Asia and Southern Europe, and is occasionally cultivated. The root was known as *radix valerianæ majoris*, and consists of an oblique rhizome which is 4 to 6 inches (10–15 Mm.) long, about $\frac{1}{4}$ inch (12 Mm.) thick, is distantly annulated, of a brown color, on the lower side furnished with numerous yellowish rootlets, and has a much weaker odor and taste than official valerian.

NARDUS SPICA CELTICA is the rhizome of *Valeriana celtica*, *Linne*, a native of the Alps. It is thin, about 3 inches (75 Mm.) long, densely covered with brown scaly leaf-remnants, has long simple rootlets on the lower side, and possesses a strong odor and taste of valerian.

NARDUS INDICA, s. **SPICA NARDI**, or true *spikenard*, formerly much employed, is obtained from *Nardostachys* (*Valeriana*, *Roxburgh*) *Jatamansi*, *De Candolle*, indigenous to India. It is about $\frac{1}{2}$ inch (6 Mm.) thick, densely beset with numerous fibrous remnants of leaf-stalks, and has a bitter aromatic taste and penetrating odor resembling that of *serpentaria*.

PATRIŇIA SCABIOSÆFOLIA, *Link.* The root is known in Japan as *kesso*, and was sent to England in 1879. It resembles valerian in appearance, odor, and taste, but has a short rhizome, not over $\frac{1}{2}$ inch (8 Mm.) thick, and this is densely covered with dark-brown scaly rootlets, which are 2 to 4 inches (5–10 Cm.) long.

Medical History.—Valerian is described by ancient authors as diuretic and emmenagogue, as a remedy for epilepsy, and locally as a detergent. The singular passion for it displayed by cats has long been known. Valerian was anciently called in English *setivall*, a name properly applied to *zedoary*; and the root was so much valued for its medicinal virtues that, as Gerarde (1567) remarks, the poorer classes in the north of England esteemed “no breaths, pottage, or physcally meats” to be worth anything without it. Its odor, now considered intolerable, was not so regarded in the sixteenth century, when it was the custom to lay the roots among the clothes as a perfume in the same way as those of *Valeriana Celtica*, *Linne*, and the Himalaya valerians are still used in the East (*Flückiger and Hanbury, Pharmacographia*).

Physiological Action.—When taken habitually in moderate doses, valerian improves the appetite and digestion without confining the bowels. 2 drachms at a single dose may occasion a sense of heat and weight in the abdomen, eructations, and even vomiting, colic, and diarrhœa; also some excitement of the pulse, general warmth, and either perspiration or diuresis. In somewhat smaller doses its operation is chiefly restricted to the nervous system; it renders the mind tranquil, disposes to good-humor and activity, produces sometimes a lively formication in the hands and feet, and a sensation about the head and spine which has been compared to the aura epileptica. Sometimes, on the contrary, there is a sense of embarrassment in the head, with heaviness

and pain. In states of morbid nervous excitement without fever, when through exhaustion the pulse has become small and frequent, valerian lessens its frequency and increases its force and volume.

Given to rabbits in doses of from 1 to 3 drachms, valerianic acid renders the heart's action more rapid, but feebler: the respiration is hurried at first, and then slower; and death usually takes place in three or four hours, preceded by prostration and convulsions. If death occurs speedily, the gastric mucous membrane is pale, but if delayed it may be congested; the kidneys are apt to be congested and the urine bloody. Oil of valerian appears to lessen the excitability of the spinal cord, and even to paralyze it, since two Gm. ($\frac{1}{2}$ gr.), injected under the skin of a frog, have been found capable of preventing tetanic spasms after a like injection of 5 Mgm. ($\frac{1}{2}$ gr.) of strychnine. Given alone to these animals hypodermically, it impairs mobility and sensibility. Valerianic acid, applied to the human skin, produces a white spot, followed by irritation and redness, and upon the tongue it may cause the epithelium to exfoliate.

Medical Uses.—Valerian is not a cure for *hysteria*, but it is a most valuable palliative when employed to avert or mitigate hysterical paroxysms provoked by some accidental cause. Especially is this the case in females of weak constitution and excitable temperament, and who are exhausted by care and anxiety. It is still more efficient in preventing the development of those hysteroidal attacks which weak and morbidly sensitive girls and women are liable to, and which consist in an excessive susceptibility to impressions, and in the power of converting into real sensations the suggestions of a disordered fancy, whereby countless subjective perceptions and various disordered actions of the lungs, heart, stomach, etc. arise. In mild cases of *mental derangement*, especially when caused by nervous shock or strain; in nervous *atony* simulating paralysis; in cases also of irregular distribution of the blood, accompanied, it may be, with indications of cerebral congestion, or, on the other hand, of cerebral *æmæmia*, of which the chief symptoms are *vertigo*, a sense of rush of blood to the head, or fainting, confusion of sight and hearing, etc., which more than at any other time are apt to occur about the menopause, —valerian is the most promptly efficient of all the palliatives that have been used. In all these cases valerian exhibits the same potency as *asafetida*, musk, and castor, and more decidedly. Oil of valerian dissolved in ether may be administered by inhalation in such attacks. Valerian is one of the best remedies for *nervous headache*, especially when it is associated with ammonia, as in the ammoniated tincture of valerian or the popular valerianate of ammonium. These preparations may be used advantageously, along with a carminative tincture, in cases of *flatulence* accompanied with palpitation of the heart. The same medicines are equally efficient in relieving *infantile colic*, an affection for which domestic medicine generally provides an analogous remedy in catnip.

Valerian is one of the innumerable articles that from time to time have been vaunted as remedies for *epilepsy*, and, allowing for the common error of confounding epilepsy with epileptiform reflex convulsions, and even with hysteria, there can be no doubt that it has sometimes cured the disease in females and young children, and especially when it originated in fright or some analogous impression. Even in these cases it must be administered in large doses and be long continued, while other and especially hygienic measures are employed to give permanent strength to the nervous system.

Valerian is useful in the treatment of the milder forms of *delirium tremens*, especially when they follow surgical operations or injuries, and in the ataxic phenomena which belong to the *typhoid state* of fevers and inflammations. It has had some reputation as a *vermifuge* for children when associated with purgatives, such as jalap, and by enema as a remedy for ascarides of the rectum. It has also been used successfully for the relief of *dysmenorrhæa* and in *polyuria* or *diabetes insipidus*. Bouchard, however, claims that when the urine contains an excess of urea (*azoturia*) or of sugar (*glycosuria*), valerian diminishes the amount of solids discharged and thus acts as a conservator of tissue and of force.

Valerian may be prescribed in powder in doses of from 30 to 90 grains (Gm. 2–6), repeated three or four times a day. Its disagreeable taste may be masked by the addition of an aromatic powder. Of its several preparations, the infusion and the fluid extract are to be preferred; next to these ranks the oil. The tincture, however, is official, and so is the ammoniated tincture, which is decidedly preferable to either the simple tincture or the fluid extract.

VALERIANATE OF CAFFEINE (so called) was tried by Paret (1875) in hysteria to moderate *nervous vomiting*, and in some cases with success, the medicine appearing to act as a general stimulant; in the vomiting of phthisis it was useless, but in *whooping cough* it

decidedly lessened the paroxysms. It was given in pills, in the dose of 2 grains (Gm. 0.10), three times a day.

VANILLA, U. S.—VANILLA.

Fructus (s. Siliqua) vanillæ, P. G.—*Vanille*, Fr., G.

The prepared unripe fruit of *Vanilla planifolia*, *Andrews*. Bentley and Trimen, *Med. Plants*, 272.

Nat. Ord.—*Orchidaceæ*.

Origin.—The name "vanilla" is derived from the Spanish *baynilla*, the diminutive of *bayua*, a pod. The plant is indigenous to Eastern Mexico, where it grows in hot, moist woods, and is cultivated by fastening shoots to trees just above the ground, where they soon strike root, begin to produce fruits in about three years, and continue to bear for about thirty years. The plant has a long, fleshy stem, supporting itself by simple aerial rootlets, alternate sessile, fleshy, oval-lanceolate leaves, and axillary spikes of large greenish-white flowers, with a depressed recurved and crenate lip, and with an elongated, fleshy, cylindrical ovary. The cultivated plant is Schiede's *Vanilla sativa*. The wild growing plant (Schiede's *V. sylvestris*) is usually regarded as a mere variety of the former, and yields a smaller and less aromatic fruit, known in Mexico as *baynilla cimarrona*. The vanilla-plant has been introduced into some of the West Indian islands, into Bourbon, Madagascar, and several East Indian islands. In its native country it is probably fertilized through the agency of insects; in other countries artificial fertilization is required.

Collection.—The fruit is collected before it is ripe, when the green color begins to change. In order to develop its aroma and to prevent its dehiscence, the unripe fruit is partly sun-dried or exposed to artificial heat, and then wrapped in blankets until it begins to sweat, when the exposure and subsequent wrapping up are repeated. Steeping in hot water is said to be in some places resorted to previously to drying. Some of the constituents are supposed to undergo a kind of fermentation, through which the odorous principle is developed. After the fruits have obtained the proper dark color, agreeable aroma, and sufficient dryness, they are tied into bundles of fifty, weighing a little over 8 ounces, and these are sometimes wrapped in tin-foil and packed in tin boxes. 16,570 pounds of vanilla were imported into the United States in 1877, and 98,542 pounds in 1882.

Properties.—The cultivated vanilla-fruit is known in Mexico as *baynilla corriente*, and is further distinguished and assorted according to its size and the thickness of its integuments. The finest quality attains a length of 12 inches (30 Cm.), has a thin pericarp, and is rarely seen in our market. The varieties usually met with are from 6 to 10 inches (15–25 Cm.) long, about $\frac{1}{8}$ inch (8 Mm.) thick, and somewhat triangular, but flattened. Vanilla is of a dark-brown color, glossy, longitudinally wrinkled, somewhat narrowed at both ends, bent or hooked at the base, and rather oblique at the apex. The surface is frequently marked with a few circular or oblong warts, and some varieties are more or less covered with an efflorescence of acicular crystals. The integuments of the fruit are leathery, of a brown color; the interior is filled with a blackish-brown fragrant pulp, in which very numerous minute black flattish-ovate seeds are imbedded. The fruit is one-celled, and has three parietal placentæ, each projecting with four curved branches into the interior. The parenchyma of the integuments contains extractive, oil drops, and crystals of vanillin and calcium oxalate, and an irregular circle of about twenty delicate fibro-vascular bundles.

Varieties.—Mexican vanilla is regarded as the best. Bourbon vanilla resembles it, and is usually covered with crystals, but has an odor somewhat suggesting that of tonka. Costa Rica vanilla is less attenuated at the ends, and has hardly the fine flavor of the Mexican variety. Vanilla from the Seychelles is considerably thinner. A vanilla is produced in Venezuela which is 3 to 6 inches (7–15 Cm.) long, rather thick, and of a decided tonka flavor. *Van. microcarpa*, *Karsten*, a native of Venezuela, has a very aromatic fruit, about 3 inches (75 Mm.) long and $\frac{1}{8}$ inch (5 Mm.) broad. In Brazil, Peru, and other parts of South America a broad and fleshy vanilla is obtained which is 6 to 8 inches (15–20 Cm.) long, about $\frac{1}{4}$ inch (12 Mm.) wide, and of an inferior vanilla odor; it is probably the fruit of *Vanilla pompona*, *Schiede*. It is not unlikely that several other species besides those mentioned above yield vanilla, but the different species are very imperfectly known. *Vanilla guianensis*, *Splitberger*, indigenous to the north-eastern portion of South America, may yield some of the South American vanilla. *Vanilla pal-*

marum, *Lindley*, a native of Bahia, has a thick cylindrical not very fragrant fruit about 2 inches (5 Cm.) long. *Vanilla aromatica*, *Swartz*, is indigenous to South America, but not to Mexico, and its fruit is said to be not aromatic.

Constituents.—According to the analysis of Bucholz (1828), vanilla contains about 11 per cent. of fixed oil, 2.3 per cent. of soft resin, 6 per cent. of sugar, 11 per cent. of gum, and considerable extractive matter. Leutner (1872) obtained 4 per cent. of resin, 6.6 gum, 10 sugar, 4.7 per cent. of ash, and, besides a little wax and tannin, also oxalic and other acids. The odor of vanilla is not due to a volatile oil. The crystalline efflorescence was for a long time regarded as identical with either benzoic or cinnamic acid, but Bley (1831) proved it to be distinct from both, and Gobley (1858) established its difference from coumarin and named it *vanillin*. It is obtained from the alcoholic extract of vanilla by diffusing it in a little water, agitating with ether, and evaporating the ethereal liquid; the brown odorous residue yields to boiling water vanillin, which is purified by recrystallization and treatment with animal charcoal. Vanillin crystallizes in hard, colorless, four-sided prisms; has the odor of vanilla and a pungent, warm taste, melts near 80° C. (176° F.); sublimes when carefully heated; has a feeble acid reaction, and is freely soluble in boiling water, in alcohol, ether, fats, and volatile oils. It does not decompose alkaline carbonates, but dissolves in caustic alkalies, and is precipitated unaltered from the solutions on the addition of an acid; its aqueous solution is not affected by salts of tin, mercury, and silver, yields a pale-yellowish precipitate with basic lead acetate, and strikes a dark-violet color with ferric chloride. It dissolves in sulphuric acid with a yellow color, and by nitric acid is oxidized to oxalic acid. On account of its feeble acid properties Stokkebye (1864) proposed to name it *vanillic acid* (see below). Carles (1870) found its formula to be $C_8H_8O_3$, and this was corroborated by Tiemann and Haarmann (1874-78), who prepared vanillin artificially from *coniferin*, $C_{16}H_{22}O_8$, a compound contained in the sap of coniferous trees; this on being treated with emulsin is split into sugar and *coniferyl alcohol*, $C_{10}H_{12}O_3$, which on being oxidized with a mixture of sulphuric acid and potassium bichromate, like coniferin itself, yields vanillin. Vanillin was recognized as the aldehyd of methyl-protocatechuic acid, $C_6H_3.OCH_3.OH.CHO$; by careful oxidation this is converted into the nearly inodorous *vanillic acid*, $C_6H_3.OCH_3.OH.COOH$. The same authors have further shown the relation of these interesting principles to creosol, eugenol, ferulic acid, caffeic acid, and other compounds, and devised a process for the artificial preparation of vanillin from oil of cloves, and proposed (1875) to estimate the amount of vanillin by completely exhausting not less than 30 Gm. of cut vanilla with ether, concentrating the ethereal tincture, agitating the liquid repeatedly with the solution of bisulphite of sodium, decomposing the mixed aqueous liquids with dilute sulphuric acid, and dissolving the liberated vanillin by agitation with ether. Mexican vanilla yielded 1.3-1.7, Java vanilla 1.6-2.75, and Bourbon vanilla 0.75-2.9 per cent. of pure vanillin; the last two varieties were found to contain, in addition, an oily matter having a disagreeable odor; and the fruit of *Van. pompona*, which yielded .4-.7 per cent. of vanillin, was observed to contain another compound, probably *benzaldehyd*, which modifies the odor of the former.

The poisonous effects repeatedly observed to be due to the use of vanilla as a flavor for ices have been referred by Schroff, in the absence of metallic poisons, to the presence of cardol, resulting from the alleged employment of the fixed oil of the cashew-nut (see p. 201) for improving the appearance of vanilla.

Pharmaceutical Uses.—Vanilla is employed in perfumery, for preparing Tinet. vanillæ, *U. S.*, and as a flavoring ingredient in Troch. ferri, *U. S.*

PULVIS VANILLÆ CUM SACCHARO, *F. Cod.*, VANILLA SACCHARATA. 1 part of finely-cut vanilla and 9 parts of sugar are triturated together until a grayish-white uniform powder is obtained, or 2 parts of vanillin dissolved in alcohol are mixed with 98 parts of sugar.

SYRUPUS VANILLÆ. Mix simple syrup with sufficient tincture of vanilla until the desired flavor is obtained.

Medical Action and Uses.—Workmen engaged in handling vanilla-beans are said to suffer from itching of the hands and face; the skin is covered with a pruriginous eruption, and swells, reddens, and desquamates. Others are affected with dizziness, weariness, and muscular pains. The eruption is produced by an acarus, which irritates without penetrating the skin (*Jour. Amer. Med. Assoc.*, i. 621). In Mexico, its native country, the Spanish conquerors found vanilla in common use for flavoring chocolate, and for this purpose it continues to be extensively used. Very probably it promotes the digestion of this aliment, as it does that of many other fatty and farinaceous articles of food, and

therefore may be classed with the aromatics. In its action it has some analogy with balsam of Peru. Like the aromatics generally, aphrodisiac qualities are attributed to it. In medicine it is rarely employed alone, but it may be prescribed in powder in *doses* of from 5 to 30 grains (Gm. 0.30–2), mixed with sugar. A syrup made with it and the officinal tincture form agreeable flavoring ingredients of mixtures. It may be added also to troches for a similar purpose, as it is in the officinal troches of iron.

VAPORES.—INHALATIONS.

These are mixtures consisting of water with a volatile substance which are perhaps never made by the apothecary, and appear to be better adapted for extemporaneous prescription. The *vapores*, as originally employed in medicine, are external applications.

VAPOR ACIDI HYDROCYANICI, *Br.*—INHALATION OF HYDROCYANIC ACID.

Take of Diluted Hydrocyanic Acid 10 to 15 minims; Water (cold) 1 fluidrachm. Mix in a suitable apparatus, and let the vapor that arises be inhaled.—*Br.*

Medical Action and Uses.—The “inhalation of hydrocyanic acid” is too dangerous a remedy to be recommended under any circumstances. The difficulty, if not impossibility, of determining the exact strength of the solution, the various degrees of susceptibility to its action, and the promptly fatal effects of an overdose inhaled, should condemn it as a medicine.

VAPOR CHLORI, *Br.*—INHALATION OF CHLORINE.

Take of Chlorinated Lime 2 ounces; Water (cold) a sufficiency. Put the powder into a suitable apparatus, moisten it with the water, and let the vapor that arises be inhaled.—*Br.*

Medical Uses.—This preparation is a convenient means of obtaining chlorine for inhalation, but the necessity of making it officinal by prescribing the exact amount of chlorinated lime to be used is the reverse of apparent.

VAPOR CONINÆ, *Br.*—INHALATION OF CONINE.

Take of Juice of Hemlock $\frac{1}{2}$ fluidounce; Solution of Potash 1 fluidrachm; Distilled Water 1 fluidounce. Mix. Put 20 minims of the mixture on a sponge in a suitable apparatus, so that the vapor of hot water passing over it may be inhaled.—*Br.*

The potassa is added for the purpose of liberating the conine contained in the juice.

VAPOR CREASOTI, *Br.*—INHALATION OF CREASOTE.

Take of Creasote 12 minims; Boiling Water 8 fluidounces. Mix the creasote and water in an apparatus so arranged that air may be made to pass through the solution and may afterward be inhaled.—*Br.*

VAPOR IODI, *Br.*—INHALATION OF IODINE.

Take of Tincture of Iodine 1 fluidrachm; Water 1 fluidounce. Mix in a suitable apparatus, and, having applied a gentle heat, let the vapor that arises be inhaled.—*Br.*

Medical Uses.—According to our experience, the proportion of tincture of iodine in this “inhalation” is entirely too large for ordinary use if the iodine is vaporized rapidly. It should be left to the judgment of those who are skilful enough to use such a preparation at all. Conine, creasote, and iodine are more efficaciously used by inhalation in atomized solutions.

VAPOR OLEI PINI SYLVESTRIS, *Br.*—INHALATION OF FIR-WOOL OIL.

Take of Fir-wool Oil 40 minims; Light Carbonate of Magnesium 20 grains; Water a sufficiency. Rub the fir-wool oil with the carbonate of magnesium and gradually add sufficient water to produce 1 fluidounce. Put 1 fluidrachm of this mixture with 10 ounces of boiling water into an apparatus so arranged that air may be made to pass through the solution and may afterward be inhaled.—*Br.*

VERATRINA, U. S., Br., F. Cod.—VERATRINE.

Veratria, Br.; *Veratrinum*, P. G.—*Vératrine*, Fr.; *Veratrin*, G.

Formula $C_{32}H_{52}N_2O_8$. Molecular weight 592.

Origin.—The mixture of alkaloids which is recognized by the pharmacopœias under the above names was first prepared by Meissner (1819) from *sabadilla* and named *sabadilline*. Pelletier and Caventou (1819) prepared similar substances from *sabadilla* and white *veratrum*, and called them *veratrine*, which name has since been applied to the product from the former source only (see also VERATRUM ALBUM), and this was known in an amorphous condition, and supposed to be uncrystallizable until Merck (1855) showed that a portion of it could be crystallized. *Sabadilla*-seeds are used for preparing veratrine; Schroff (1863), however, has shown that the capsules are very poisonous and probably contain the same alkaloids.

Preparation.—Take of *Cevadilla* 2 pounds; Distilled Water, Rectified Spirit, Solution of Ammonia, Hydrochloric Acid, each a sufficiency; Purified Animal Charcoal 60 grains. Macerate the *cevadilla* with half its weight of boiling distilled water in a covered vessel for 24 hours. Remove the *cevadilla*, squeeze it, and dry it thoroughly with a gentle heat. Beat it now in a mortar, and separate the seeds from the capsules by brisk agitation in a deep, narrow vessel or by winnowing it gently on a table with a sheet of paper. Grind the seeds in a coffee-mill, and form them into a thick paste with rectified spirit. Pack this firmly in a percolator, and pass rectified spirit through it till the spirit ceases to be colored. Concentrate the spirituous solution by distillation so long as no deposit forms, and pour the residue, while hot, into twelve times its volume of cold distilled water. Filter through calico, and wash the residue on the filter with distilled water till the fluid ceases to precipitate with ammonia. To the united filtered liquids add the ammonia in slight excess; let the precipitate completely subside, pour off the supernatant fluid, collect the precipitate on a filter, and wash it with distilled water till the fluid passes colorless. Diffuse the moist precipitate through 12 fluidounces of distilled water, and add gradually, with diligent stirring, sufficient hydrochloric acid to make the fluid feebly but persistently acid. Then add the animal charcoal, digest at a gentle heat for 20 minutes, filter, and allow the liquid to cool. Add ammonia in slight excess, and when the precipitate has completely subsided pour off the supernatant liquid, collect the precipitate on a filter, and wash it with cold distilled water till the washings cease to be affected by nitrate of silver acidulated with nitric acid. Lastly, dry the precipitate first by imbibition with filtering-paper, and then by the application of a gentle heat.—*Br.*

Alcohol extracts from *sabadilla*-seeds veratrine in its natural combination with veratric acid. On evaporating the alcohol, diluting the syrupy liquid with water, and filtering from the resin the liquid contains veratrate of veratrine, and this salt is decomposed by ammonia or potassa; the alkaloid thus isolated requires to be purified by washing with water, dissolving in a dilute acid, and freeing from coloring matter by animal charcoal; ammonia will then precipitate veratrine as a white powder.

The concentrated alcoholic extract may also be deprived of its alkaloidal constituents by boiling with acidulated water, and the acid solution decomposed by magnesia, the excess of which remains with the liberated alkaloids; the latter are taken up by alcohol combined with sulphuric acid, the alcohol evaporated, the remaining aqueous solution decolorized by animal charcoal, and the veratrine precipitated by ammonia. This was the process of the U. S. P. 1870.

The outlines of the process of the French Codex are as follows: Exhaust with alcohol acidulated with sulphuric acid, add slaked lime to the tincture to liberate the alkaloids, filter from the calcium compounds, distil off the alcohol, dissolve the residue in dilute sulphuric acid, decolorize by means of animal charcoal, precipitate by ammonia, again dissolve in alcohol, and repeat the treatment as before; finally, dissolve the washed and dried veratrine in ether, filter, and evaporate spontaneously.

Several other processes have been recommended for the preparation of veratrine, in which advantage is taken of its ready solubility in acidulated water. Delondre (1855) exhausts the powdered seeds by percolation with water acidulated with hydrochloric acid, precipitates with potassa, and exhausts the washed and dried precipitate with ether, on the evaporation of which the alkaloid is left behind. Merck's process is somewhat similar: powdered *sabadilla* is boiled with very dilute hydrochloric acid, the solution concentrated to a syrupy consistence, and further acidulated with hydrochloric acid as long as a precipitate of veratric acid appears. The filtrate is precipitated with lime; the precipitate is collected and exhausted with alcohol; the alcohol is distilled off, and the residue

dissolved in dilute acetic acid. On the addition of ammonia, veratrine is precipitated; it is obtained as a crystalline powder by dissolving it in ether and evaporating, as directed by the French Codex.

Properties.—As obtained by the first process, veratrine is a white or whitish amorphous powder, permanent in the air, without odor, powerfully sternutatory, and very irritating to the nostrils, and has a persistently acrid taste, "leaving a sensation of tingling and numbness on the tongue and producing constriction of the fauces" (U. S.). It imparts to water an acrid taste, but requires about 1000 parts of boiling water for solution, the excess of the alkaloid cohering in lumps without melting. It has an alkaline reaction to test-paper, neutralizes acids, and when heated melts, and afterward is decomposed, forming a spongy charcoal, and is finally dissipated without leaving any residue. Veratrine is soluble in 3 parts of alcohol and dissolves in about 6 parts of ether (Delondre), in 1.6 (Pettenkofer) or 8.6 (Schlimpert) parts of chloroform; in 96 parts of glycerin (Cap and Garot) and 56 parts of olive oil (Pettenkofer). Nitric acid imparts to veratrine a yellow color or forms a reddish-yellow solution. Its solution in concentrated hydrochloric acid acquires by heat a deep-red color, which remains unaltered for several weeks (Trapp 1862). Sulphuric acid dissolves veratrine with a yellow color, changing in a few minutes to orange-red, then to blood-red, in about 30 minutes to carmine-red, and subsequently to violet color (Henry). Masing (1869) observed that .00017 Gm. of veratrine may be detected with the last two tests, but that the reaction with hydrochloric acid is less interfered with by the presence of extractive matter. The fresh solution of veratrine in sulphuric acid becomes at once purple-colored on the addition of bromine-water. "On triturating 1 part of veratrine with 100 parts of sulphuric acid, the solution shows a green-yellow fluorescence, the color gradually changing to red" (P. G.). The U. S. P. directs for this test no definite quantity of sulphuric acid, but states that the fluorescence first observed becomes more intense on adding more sulphuric acid. On sprinkling powdered sugar upon a thin layer of the solution of veratrine in sulphuric acid, a yellow color is produced, changing to green and blue, and becoming paler after an hour (Weppen, 1874).

Tests.—The tests just described establish the identity of veratrine. On being ignited upon platinum-foil no residue should be left.

Composition.—The formula given above is that ascertained by Merck for the crystalline alkaloid in large colorless, rhombic prisms, which on exposure become white, opaque, and friable, and lose their shape in boiling water without melting or dissolving. The crystals are obtained by dissolving medicinal veratrine in alcohol, adding water until a permanent precipitate begins to appear, and evaporating spontaneously; the residue will consist of crystals imbedded in a brown amorphous resin-like mass, which is removed by cold alcohol, after which the crystals may be purified by recrystallizing from strong alcohol. Weigelin (1871) ascertained that veratrine exists in two distinct modifications, one of which is soluble in water, and by heating the solution is converted into the insoluble variety, which has a resinous appearance; analysis led to the composition $C_{55}H_{86}O_2N_{15}$. According to E. Schmidt (1877), commercial veratrine contains three distinct modifications—namely, a crystalline base soluble in water, and two amorphous bases, one of which is soluble, the other insoluble, in water. The crystalline base predominates, and is regarded by Schmidt as veratrine proper; he gives it the formula $C_{32}H_{50}NO_9$; its platinum-chloride was found to be easily soluble in alcohol, less soluble in water, and insoluble in ether. The amorphous modifications appear to have the same formula, which differs from that given by Merck chiefly in the amount of nitrogen.

On treating medicinal veratrine with ether, a residue is left from which Couërbe (1834) isolated a second crystallizable alkaloid, *sabadilline*, for which Weigelin gives the formula $C_{11}H_{66}N_2O_{13}$. It is not sternutatory, and dissolves more or less freely in water, benzol, petroleum benzin, amylie alcohol, and chloroform; neutralizes the acids completely, but yields amorphous gum-like salts with sulphuric and hydrochloric acid, which are not precipitated by alkalies or their carbonates, and yield but slight precipitates with phosphotungstic acid and potassio-cadmium iodide. That portion of medicinal veratrine which is soluble in ether yields to hot water, in which veratrine is insoluble, a third alkaloid, which Weigelin named *sabatrine*, and found to have the composition $C_{31}H_{56}N_2O_{17}$. It is likewise soluble in benzol, petroleum benzin, amylie alcohol, and chloroform, is amorphous and yields amorphous salts, which are precipitated by hot potassium hydrate and carbonate if not added in excess.

The most recent investigation on the *sabadilla* alkaloids was made by C. R. A. Wright and A. P. Luff (1878), who were unable to find *sabadilline*. They regard *sabatrine* as an

alteration-product. They retain the name *veratrine* for the amorphous alkaloid of medicinal veratrine, and deny the existence of isomeric modifications; they give it the formula $C_{37}H_{53}NO_{11}$, and state that on saponification it splits up into veratric acid and a new base, *verine*, $C_{28}H_{45}NO_8$. Merck's crystallizable base is named by them *cevadine*, and is stated to have the composition $C_{32}H_{49}NO_9$, and, on saponification, to be resolved into a new base, *cevine*, $C_{27}H_{43}NO_8$, and the cevadic acid of Pelletier and Caventou, which is methyl-crotonic acid, $C_5H_7O_2$. The third alkaloid, *cevadilline*, $C_{34}H_{53}NO_8$, is insoluble in ether, is probably identical with sabadilline, but separates in an amorphous condition from benzol, and on saponification yields methyl-crotonic acid and the base *cevilline*. 20 pounds of sabadilla-seeds yielded between 60 and 70 Gm. of mixed alkaloids.

It will be observed that medicinal veratrine is a mixture of two or three alkaloids naturally existing in sabadilla, and of several derivatives from these alkaloids.

Off. Prep.—Oleatum veratrinæ, *U. S.*; Ung. veratrinæ, *U. S.*, *Br.*

Physiological Action.—*On Animals:* The action of this alkaloid has been illustrated by numerous experimenters, who agree substantially in their description of it. Administered in moderate doses to hogs, horses, and other quadrupeds, it occasions anxiety and restlessness, a profuse secretion of saliva, colic, vomiting, and purging (the last effects whether the agent is administered by the mouth or hypodermically), general muscular debility, and some spasmodic movements. Under the influence of larger doses the nervous phenomena, spasmodic as well as paralytic, are more marked; the limbs are unable to support the body; the action of the heart becomes slow, irregular, and intermittent, and the respiration deep and labored; the vomiting is violent, and the stools may be bloody. In directly fatal doses veratrine depresses the whole nervous system; the respiration and circulation are gradually suspended, the convulsive movements pass into tetanus, the rigidity of the muscles of the chest impede respiration, and death takes place by asphyxia. Accordingly, after death the lungs and heart are found gorged with blood, and the latter organ has lost its irritability, but there is no trace of inflammation of the stomach. The tetanizing and paralyzing actions of veratrine appear to occur as direct effects of the poison upon the muscles, and not through the intervention of the spinal cord, for they may take place in the muscles of a limb whose nervous connection with the spinal marrow is destroyed; and, conversely, they do not occur when, all other connections being severed, the spinal nerves communicating with the limb are left intact. That the tetanizing effect results not from an action of the poison upon the spinal marrow, but from a direct action upon the muscles or upon the ends of the nerves, is also to be inferred from the fact that in the animal operated upon tetanic spasm is not excited by a direct mechanical irritation of the nerves, but by the voluntary muscular acts of the animal. It also follows irritation of the muscles themselves, which may then take on prolonged, and even permanent, tetanic contraction until their vitality is completely exhausted. Karewski's experiments on frogs show that veratrine arrests the heart in systole, precisely as digitalis does, by progressively increasing the contraction of the heart-muscles (*Zeitsch. f. klin. Med.*, v. 450); and those of Pécholier and Redier equally demonstrate that it arrests the heart in diastole (*Bull. de thérap.*, cv. 430).

On Man: Veratrine has a bitter and acrid taste, and the least portion of it placed upon the tongue produces a peculiar and persistent numbness and tingling, with irritation of the throat and salivation. The minutest quantity of it introduced into the nostrils, and even the casual approach of a vial containing it to the nose, occasion protracted irritation and sneezing, and sometimes coughing. Applied in alcoholic solution or in an ointment to the sound skin, it produces a slight prickling sensation, and upon very delicate portions of the integument a pain compared to that which might be occasioned by its puncture with hot needles. The pain, however, is transient, and is followed by a sense of coolness and numbness. If the preparation is strong and is applied with friction, an eruption of vesicles may follow. If well rubbed in, particularly upon the face, slight twitching of the muscles is sometimes observed, and, more rarely, formication, which extends to remote parts of the body. Applied to the denuded skin or injected hypodermically, it causes severe pain, muscular twitching, and the other ordinary effects of its internal administration. These effects vary with its dose. The fortieth and from that to the twentieth of a grain (Gm. 0.001–0.003) occasions tingling which begins in the fingers and toes, and thence extends to the whole body, followed by a sense of numbness in the same parts and more or less lowering of the pulse. If the usual limit of medicinal doses is exceeded, and from one-twentieth to one-tenth of a grain (Gm. 0.003–0.006) of the alkaloid or of its acetate is taken, there may occur great faintness and pallor; increased frequency, irregularity, and weakness of the pulse; nausea and vomiting, usually of

bilious liquids; diarrhœa, sometimes with bloody stools; cold sweating and muscular twitching; and aching along the spine. If the dose is repeated at intervals, the gastrointestinal symptoms subside, but the pulse falls considerably below the normal rate. There is also a good deal of irritation and constriction of the fauces, with secretion of mucus.

A woman who swallowed about 3 grains (Gm. 0.20) of veratrine in a liniment containing chloric ether and opium was affected with giddiness, faintness, nausea, thirst, diarrhœa, tenesmus, and constriction of the abdomen; the tongue was swollen, the mouth and throat sore, the pupils contracted, the breathing hurried, the pulse small and quick, the action of the heart feeble. There was extreme itching of the skin which lasted for several days, a tingling which did not cease for two months, and a peculiar spasmodic snapping of the lower jaw (*St. George's Hosp. Rep.*, v. 69).

Medical Uses.—Veratrine was used first internally as a remedy for *neuralgia*, and in the most obstinate form of that affection, *sciatica*, which so often depends upon material alterations of structure. It is now very seldom given internally in this or any other variety of neuralgia, but is of common use as a topical application in the functional forms of the affection. Although inferior for this purpose to aconitine, it is nevertheless efficient in many cases of neuralgia of the fifth pair, of the intercostal nerves, and others. Very probably it acts both by obtunding the sensibility of the painful part and by its counter-irritant operation upon the skin when it is applied in due strength directly to the sensitive points of the nerve. It is sometimes injected hypodermically, $\frac{1}{4}$ grain (Gm. 0.01) at a time, but an application of the official ointment of veratrine is preferable. It is rendered much more efficient by the addition to each drachm of it of 2 or 3 grains of muriate or sulphate of morphine. In various forms of *pruritus* the topical use of veratrine is an efficient palliative. It may be given internally with advantage when the itching is general.

In the treatment of *acute articular rheumatism* this medicine has been systematically employed, by beginning on the first day of the treatment with a single dose of $\frac{1}{10}$ grain (Gm. 0.005), and on each successive day giving an additional dose until the sixth or seventh day, unless the disease sooner yielded or the toxic effects of the medicine were developed. In the latter case it was suspended or its dose diminished. It was claimed for this treatment that it speedily reduced the fever and subdued the pain of the disease, and that in a patient of unimpaired constitution it frequently triumphed over an acute attack of the disease in a week. It was further asserted that it did not, like copious bloodletting, exhaust the patient's strength and develop anæmia. This advantage over the older sanguinary method may be admitted, but there is not a shadow of evidence to demonstrate its power of shortening an attack of rheumatism, or, above all, of preventing the most serious of the ordinary complications of the disease, inflammation of the heart and its membranes. Indeed it is seldom employed at present, and those who imagine that the cure of rheumatism consists in repressing certain of its symptoms find in the preparations of green hellebore equally efficient and less dangerous agents. The same remark is literally applicable to the use of veratrine in *pneumonia*. The strongest reason that could be found by an eminent therapist for employing veratrine in this disease was that "the results from its use appear to be comparable to those of the antimonial treatment" (Trousseau). But since the latter is one of the most mischievous that was ever employed, the merit of the former may be duly estimated. If some will use this medicine as they would green hellebore, digitalis, aconite, etc. in febrile affections, they should be prepared with diffusible stimulants to combat its sedative effects when they grow alarming.

Veratrine has occasionally been used to allay disordered action of the heart in acute and also in chronic diseases of that organ, and it may sometimes become a useful palliative of this distressing symptom, and thereby even avail to diminish cardiac dropsies. But for such purposes other preparations of veratrum are preferable. It is unnecessary to discuss its virtues in eruptive fevers or in typhoid fever, for which it has sometimes been prescribed, or in nervous affections, such as whooping cough, chorea, hysteria, and functional paralysis, or to do more than state the fact of its having been employed topically to reduce enlarged glands, serofulous swellings of joints, etc. It is sufficient to state that Liebermeister (*Handbuch des Fiebers*, S. 643), even while advocating its use, warns against giving it to persons with a feeble heart, and, while admitting that it may produce collapse, claims that food and alcohol will rescue the patient from that peril. It is alleged by Férís that various *tremors*, including those due to alcohol, fever, nervous degeneration,

etc., are benefited by veratrine in doses of gr. $\frac{1}{120}$ (Gm. 0.0005) three or four times a day (*Practitioner*, xxxii. 212). The statement seems highly improbable.

Administration.—Owing to its very acrid taste, veratrine is generally given internally in pilular form in doses varying from $\frac{1}{10}$ to $\frac{1}{4}$ grain (Gm. 0.0016–0.016). The dose should be rapidly but cautiously increased from the minimum until nausea or slowing of the pulse occurs. Externally, the officinal ointment is a convenient preparation for application by friction, which should be made with a mop or with the finger guarded by a glove, and until a feeling of burning or prickling is perceived by the patient. Solutions in oil and in glycerin may be applied in the same manner. For endermic use from $\frac{1}{8}$ to $\frac{1}{2}$ grain (Gm. 0.008–0.033), mixed with starch, may be prescribed. Hypodermically, $\frac{1}{4}$ grain (Gm. 0.01) may be employed at a single operation, but the method is objectionable on account of the pain it occasions and the probability of abscess being caused by it. In poisoning by veratrine the stomach should first be evacuated, then washed with a solution of tannin, and the sedation combated with alcohol, ammonia, electricity, artificial respiration, etc.

Tulipine, an alkaloid derived from the common tulip, is said by Dr. Ringer to be a muscle-poison, like veratrine, although weaker. It paralyzes either the cord or the afferent nerves, or both; its action on the motor nerves, if any, is slight; it affects the heart of frogs like veratrine, and does not affect the pupil (*Practitioner*, xxv. 241).

VERATRUM ALBUM.—WHITE VERATRUM (HELLEBORE).

Rhizoma veratri, P. G.; *Radix hellebori albi*.—*Vératre* (*Hellébore*) *blanc*, Fr.; *Weisse Nieswurz*, *Weisser Germer*, G.

The rhizome (*F. Cod.*), with the rootlets (*P. G.*), of *Veratrum album*, *Linné*. Bentley and Trimen, *Med. Plants*, 285.

Nat. Ord.—*Melanthaceæ*.

Origin.—*Veratrum album* is an herbaceous perennial growing in moist meadows of the Pyrenees and Alps and eastward throughout Russia, Siberia, Northern China, and Japan. It has likewise been found in Colorado and in other parts of Western North America (*Ver. californicum*, *Durand*). The stem is 2 to 4 feet (.6–1.2 M.) high, and has numerous alternate elliptic or broadly oval, entire leaves, which are about 6 inches (15 Cm.) long, strongly ribbed and plicate, and sheathing at the base; the upper ones are smaller, narrower, and lanceolate in form. The inflorescence is a large racemose panicle 12 to 18 inches (30–45 Cm.) long, with polygamous flowers having six spreading lance-oblong, yellowish-white, and externally green sepals. The three-horned fruit consists of three partly-united follicles containing numerous flattened and winged seeds. The rhizome is collected in autumn. The variety *viridiflorum*, *Mertens et Koch* (*Ver. Lobelianum*, *Bernhardi*), grows in Europe, and differs chiefly in the more simple inflorescence, the longer bracts, and the pale-green flowers.

Description.—The rhizome of white veratrum is upright, obconical in shape, simple or occasionally divided above into two branches; it is 2 to 3 inches (5–8 Cm.) long, and about 1 inch (25 Mm.) thick, tufted above with the remnants of the leaf-bases, truncate below, the lower half beset with dead and the upper portion with yellowish fleshy nearly simple rootlets, which shrink considerably in drying and are 8 to 12 inches (20–30 Cm.) long and about $\frac{1}{12}$ inch (2 Mm.) thick. In the commercial drug the rootlets were formerly often cut off close to the rhizome, and this has been occasionally divided to facilitate the drying. The rhizome is somewhat annulate, externally of a dull black-gray color, and either closely surrounded with rootlets or tuberculated from the root-remnants; internally it is whitish or grayish-white, and shows upon transverse or longitudinal section, at a distance of about $\frac{1}{8}$ inch (3 Mm.) from the outer surface, a brownish wavy nucleus-sheath, and in the inner portion numerous small wood-bundles, which are scattered, irregularly curved in various directions, and rather crowded near the nucleus-sheath; outside thereof only a few small wood-bundles are seen passing into the rootlets. The nucleus-sheath consists of one or occasionally two rows of cells, having the inner cell-walls much thickened; the parenchyma-cells are filled with small starch-granules or a few of them with raphides of calcium oxalate. The drug is inodorous, but its dust is strongly sternutatory; its taste is bitter and burningly acrid.

FIG. 305.

Veratrum album, *Linné*.
longitudinal section of
rhizome.

Constituents.—Pelletier and Caventou (1820) obtained from white veratrum liquid and solid fat, a volatile acid, gum, starch, and an alkaloid, which they declared to be identical with veratrine, and to be combined with gallic acid. The existence in veratrum of gallic acid was, however, denied by Pfaff and by Weigand (1841). The latter found in it about 10 per cent. of pectin. E. Simon (1838) announced the isolation of a second alkaloid, *jervine*, $C_{30}H_{46}N_2O_3$. After Charles Bullock (1865) had proved the non-existence of veratrine in *Veratrum viride* Dragendorff (1872) announced its absence also from white veratrum; and this observation was corroborated by C. L. Mitchell (1874), who found in it, besides jervine, a second alkaloid, which he named *veratralbine*. Wright and Luff (1879) announced the presence in 1 kilogram of white veratrum of 4.20 Gm. of alkaloids, of which 1.30 is jervine, $C_{26}H_{37}NO_3$, 0.40 pseudojervine, $C_{29}H_{42}NO_7$, 0.25 rubijervine, $C_{26}H_{33}NO_2$, 2.20 veratralbine, $C_{28}H_{43}NO_5$, and 0.05 another sternutatory base, probably veratrine.

Jervine, when pure, is a white powder, crystallizes from alcohol, is tasteless, not sternutatory, insoluble in water and ether, soluble in alcohol and chloroform, and melts between 198° C. (Bullock) and 237° C. (Wright). Its salts with acetic and phosphoric acids are soluble in water, and these solutions are precipitated by sulphuric, hydrochloric, and nitric acids and their soluble salts. According to Bullock (1875), its acetic acid solution, treated with potassium nitrate, affords a ready method for obtaining the alkaloid in a pure state. Sulphuric acid colors jervine yellow, changing to green, and finally to turbid yellow; on the addition of bromine the green color changes to a faint brownish tint. The other color reactions (yellow by nitric or boiling hydrochloric acid) are not very characteristic.

Pseudojervine, like jervine, dissolves in strong sulphuric acid with a yellow color, the solution gradually turning green; its sulphate is tolerably soluble in water. The alkaloid melts at 299° C. and is insoluble in ether.

Rubijervine is soluble in ether, melts at 237° C., is colored red by sulphuric acid, forms a readily soluble sulphate, and is not sternutatory.

Veratralbine is white, uncrystallizable, bitter, burningly acrid, and violently sternutatory. It dissolves in alcohol, amylic alcohol, ether, chloroform, carbon bisulphide, and in dilute acids, forming soluble and uncrystallizable salts. It melts near 170° C. (338° F.) and sublimes in small feathery crystals. In its behavior to reagents it closely resembles *veratroidine*, and is regarded by Tobien (1877) as being identical with it. According to Wright and Luff, pure veratralbine is not sternutatory.

Weppen (1872) could not find Weigand's pectin, and leaves it undecided whether the presence of that compound is due to an adulteration or to the period at which the rhizome had been collected. Pelletier and Caventou's gallic acid was recognized as a new acid, called jervic acid, and the coloring matter as *veratramarin*, a light-yellow, very bitter, and deliquescent neutral principle, which is present in very minute quantity, so that 60 pounds of the rhizome yielded a quantity insufficient for a thorough chemical investigation. Veratramarin is easily soluble in water and alcohol, insoluble in ether, benzol, chloroform, and petroleum benzin, and is precipitated from its solutions by subacetate of lead and tannin.

Jervic acid, $C_{14}H_{10}O_{12} \cdot 2H_2O$, is a white crystalline powder, has an acid taste, is insoluble in benzol, carbon bisulphide, chloroform, petroleum benzin, and amylic alcohol, is very sparingly soluble in absolute alcohol and ether, and requires more than 100 parts of cold water for solution. The acid is neither fusible nor sublimable; its silver salt crystallizes from the solution in hot water, is insoluble in dilute nitric acid, and is not altered on exposure to light.

Dr. Jos. Waltl (1828) considered the rhizome, with the rootlets attached, to be more active than the rhizome alone, and Schroff (1860) announced the rootlets to have a more powerful action than the rhizome, and somewhat different from it.

Medical History.—White hellebore—or hellebore, as it was distinctively called by the Greeks—was used by them in the treatment of chronic diseases rebellious to ordinary remedies, such as insanity (especially melancholy), dropsy, diseases of the skin, tetanus, gout, hydrophobia, *tie douloureux*, etc. It was always associated with lenitives to moderate its violent action. It gradually fell into disuse.

Physiological Action.—*On Animals:* White hellebore is poisonous to all animals. Its effects are nearly the same when, experimentally, it is introduced into the system by the stomach or the blood-vessels. They consist of retching or vomiting, salivation, general debility, a small, feeble, irregular, or rapid pulse, slow and labored breathing, spasm of the abdominal muscles, general tonic or clonic convulsions, tremulousness and totter-

ing, urination, sweating, contracted pupils, and insensibility. After death the lungs are congested, and when the poison has been administered by the stomach its mucous membrane is very red.

On Man: When taken internally in poisonous doses it occasions soreness of the mouth and swelling of the tongue, burning heat in the stomach, vomiting, anxiety, tremor, vertigo, weakness of the limbs, syncope, aphonia, interrupted respiration, a feeble pulse, convulsions, sinking, distortion of the eyes, dilated pupils, blindness, mental aberration, prolonged insensibility, and cold sweating. Among these symptoms purging is not mentioned, but it occurs under the prolonged use of the drug. When death has resulted directly from poisonous doses, signs of active gastro-intestinal inflammation and congestion of the lungs have been found. In poisoning with recovery there have been observed for several days debility, tremulousness, muscular twitching, and a sense of constriction and distress in the præcordial region.

Medical Uses.—White hellebore is now hardly used as an internal medicine. Externally, it has been applied in decoction to destroy *vermin* in man and beast and for the relief of *pruritus vulvæ*. It was formerly employed in the treatment of *itch*. Its irritant properties caused it to be used as an *errhine* when diluted with starch or some other inert powder or with snuff. In this way it is sometimes made use of to relieve the frontal headache which occurs in certain cases of *coryza*. If it is administered internally the commencing dose should not exceed 1 or 2 grains (Gm. 0.06–0.12).

VERATRUM VIRIDE, U. S.—VERATRUM VIRIDE.

Veratri viridis rhizoma (radix), Br.—American or Green veratrum (hellebore), Indian poke, E.; *Vératre vert*, Fr.; *Grüner Germer*, G.

The rhizome and rootlets of *Veratrum viride*, Aiton (*Ver. album*, var. *viride*, Baker, *Melanthium virens*, Thunberg). Bentley and Trimen, *Med. Plants*, 286.

Nat. Ord.—Melanthaceæ.

Origin.—Green veratrum grows in swampy places and on the border of damp thickets in Canada, and in the United States as far south as Georgia. It resembles the white veratrum so closely that no important botanical difference between them can be ascertained, and Asa Gray remarks that it is "much too near *Veratrum album* of Europe." It more especially resembles the green flowering variety, *Lobelianum*, and Regel (1861) regarded it as identical with a variety growing in Eastern Siberia. Its flowers are yellowish-green and appear in June. The rhizome is collected in autumn.

Description.—The rhizome agrees in size, shape, color, taste, and structure so closely with that of white veratrum that it is difficult, if not impossible, to distinguish the two drugs if they have been trimmed alike. The American veratrum is nearly always dried with the rootlets attached, and these are from 4 to 10 inches (10–25 Cm.) long, about $\frac{1}{12}$ inch (2 Mm.) thick, much shrivelled, and of a light yellowish-brown color; those on the lower part of the rhizome, if present, are thinner and black. We have occasionally found considerable portions of the leaf-stalks and stems present in the commercial drug; these parts appear to be inert or nearly so, and should be rejected.

Constituents.—H. W. Worthington (1838) isolated an alkaloid from green veratrum which he regarded as identical with veratrine. The same conclusion was arrived at by J. G. Richardson (1857) and by G. J. Scattergood (1861). But Charles Bullock (1865) proved that American veratrum contains two alkaloids, neither of which is identical with veratrine. These alkaloids were subsequently named by Prof. G. B. Wood *viridine* (insoluble in ether) and *veratroidine* (soluble in ether). E. Peugnet (1872) recognized the so-called viridine as impure *jervine*, and C. L. Mitchell (1874) made the same observation. In the same year Mitchell characterized *veratroidine* as follows: It is a white uncrystallizable powder of a bitter taste, leaving a tingling sensation in the fauces, violently sternutatory, and extremely irritating. It fuses near 130° C. (265° F.), is soluble in alcohol, amyl alcohol, ether, chloroform, carbon bisulphide, and when freshly precipitated slightly in petroleum benzine. It forms soluble salts with the acids, most of which are uncrystallizable. Sulphuric acid colors it yellow, changing to dark-red. Boiling hydrochloric and nitric acids color it yellow. Tobien's (1877) elementary analysis leads to the formula $C_{51}H_{78}N_2O_{16}$ or to $C_{24}H_{37}NO_7$. He obtained both *jervine* and *veratroidine* also from the rhizome and the young leaves of *Veratrum lobelianum*, and found in the dried rhizome of *Veratrum album* but little *jervine* and a larger quantity of *veratroidine*. C. A. Robbins (1877) announced that he had isolated from American veratrum, besides *jervine*, another crystallizable alkaloid, which is soluble in ether, and which pro-

duces with sulphuric acid and sugar a yellow color changing to blue, and with sulphuric acid a yellow color quickly changing to a pink-red, and after several hours to indigo-blue; presence of jervine or of coloring matter prevents the appearance of the blue color. Bullock (1879) obtained 0.66 per cent. of mixed alkaloids. Wright and Luff (1879) only 0.08 per cent., that portion remaining with the resins probably escaping their notice. The latter investigators consider over one-half of the alkaloids to be cevadine (see VERATRINA), one-fourth to be jervine, nearly one-fifth to be *pseudojervine*, and the remainder *rubijervine*, while less than 0.0004 per cent. is regarded by them as *veratrine*, the presence of which, besides jervine, in both the American and white veratrum was announced by Prof. Wormley in 1876. Bullock, however, obtained fully two-thirds of the alkaloids as nitrate of jervine, the remainder being Wright's rubijervine, with probably some pseudo-jervine. (See VERATRUM ALBUM.)

In the investigations recorded above no notice has been taken of the probable difference in the composition of the rootlets and rhizome, as suggested by Prof. Schroff. The rhizome of American, like that of the white veratrum, contains considerable resin, from which the alkaloids are not easily purified.

Off. Prep.—Extr. veratri vir. fluid., U. S.; Tinct. veratri viridis, U. S., Br.

Medical History.—Green veratrum was well known to the aborigines of this country for its poisonous properties, and was subsequently used by farmers to poison the birds that ravaged their crops. It was also employed at a later period (1835) in the treatment of various fevers and inflammations, but its vogue remained local until 1850, when extravagant accounts of its virtues were widely disseminated. Since that time it has been more generally used both at home and abroad, but chiefly by those physicians who disregard the interdependence of morbid phenomena, forget that the suppression of a symptom is not the cure of a disease, and overlook the consideration that while the exhibition of fever may be prevented the causes of fever may be destroying life.

Physiological Action.—*On Animals:* Birds poisoned by corn soaked in an infusion of green veratrum have their muscular power temporarily so much impaired as to prevent their flying or walking. The alkaloids and resin, given internally, occasion prolonged vomiting, salivation, prostration, and slowing of the pulse. The tincture injected hypodermically in frogs, dogs, and rabbits causes the pulse to fall as much as 40, 50, or even 100 beats in a minute, while the temperature declines by from 1°–5° C., and the breathing grows slow and irregular. In animals that vomit vomiting and purging precede the other symptoms. The most conspicuous symptom is complete prostration, which no stimulants overcome, but which, in course of time, ceases spontaneously. According to Dr. H. C. Wood, veratroidine slows the respiration, and ultimately produces asphyxia, while the pulse beats rapidly. But until asphyxia threatens the heart and pulse act more slowly and the blood-pressure is reduced, and if asphyxia is prevented by artificial respiration the pulse continues to fall. In all doses it affects the respiration, but only in large doses appears to act directly upon the cardiac muscles. Its power of lowering the pulse-rate appears to be exercised through the par vagum. Like many other medicines, it produces opposite effects, inhibitory or stimulating, according as its dose is large or small. Poisonous doses are sufficient to neutralize the influence of the most intense faradaic currents. Viridine (or jervine), according to the same authority, in its action upon the circulation, and as compared with the influence upon the respiration, is much more powerful than veratroidine. Like veratroidine, it slows the pulse and lessens the arterial pressure by a direct action upon the cardiac muscles and upon the vaso-motor centres. It seems not to affect the inhibitory and accelerator nerves of the heart, as veratroidine does.

On Man: Green veratrum is a powerful irritant. Its powder, snuffed into the nostrils, causes violent and prolonged sneezing. Applied to the skin in a moist state, it occasions redness and burning. Taken internally in full doses, it excites nausea, with persistent and violent vomiting; sometimes accompanied by purging, and a reduction of the force and frequency of the pulse and the animal temperature. The pulse may be reduced to 35 or 40 in a minute, and in some exceptional cases to 22. Excessive doses give rise to the following symptoms: faintness, somnolency, coma (?), dimness of sight, dilatation of the pupils, vertigo, headache, rarely delirium, impaired muscular power, general numbness, slow and infrequent respiration, hicough, a pale cold skin covered with a clammy sweat, persistent vomiting, excruciating pain in the præcordium, flatulence, profuse watery diarrhœa in some cases, and a small, infrequent, and feeble pulse. It is remarkable that diarrhœa so rarely is present as an effect of excessive doses of this medicine, and that, notwithstanding the sedation of the heart and the general appearance of

collapse produced by them, only one case of fatal poisoning of an adult by green veratrum should have been recorded. "A gentleman aged about thirty years went into a drug-store which he frequented and helped himself to what he supposed was a *drink* of whiskey. It proved to be veratrum viride, and it killed him in about four hours" (Kirk, *Med. and Surg. Reporter*, Apr. 26, 1879). It is said to have caused death in two cases of children, the one eighteen months and the other eleven months old. It has been supposed to be an abortifacient, but there is no evidence that it is so, except in so far as all violent emetics may produce abortion.

Medical Uses.—The greater number of reports which have been published concerning the medicinal uses of green veratrum are, unfortunately, not only deficient in the details on which a judgment could securely rest, but exhibit great ignorance of the natural history of disease and of the relation of medicines to its cure. There are many reporters who attribute to this medicine equal curative virtues in asthenic and sthenic diseases, in inflammations and in fevers, and not a few who extol its virtues when it formed only one of several active agents simultaneously administered to the patient. The only conclusion to be drawn from a critical study of the mass of conflicting evidence respecting its use in the diseases referred to is, that the patients would have been better off not only without its use, but also without that of the medicines associated with it. The suggestion has been made that the effects of veratrum viride and of depletion are so similar that the drug may serve as a substitute for that operation; upon which it may be remarked that the condemnation of venesection *upon scientific grounds* has been so general and complete that to advocate a medicine on account of its supposed analogy to depletion is not to recommend it. Nor should it be forgotten that this identical reason was at one time urged in favor of substituting digitalis for depletion. Now, veratrum viride and digitalis are physiological antagonists. But venesection does much more than reduce the pulse-rate in inflammatory affections (and, indeed, in comparison with green veratrum, its action is in this respect very insignificant), it takes away from the blood a portion of the solids which sustain the inflammatory process, and supplies their place with water; it also removes from the system a portion of the effete matters produced by inflammation and which tend to convert the circulating fluid into a poison. The artificial production of perspiration by veratrum or by any other medicine does not accomplish this purpose. It may in this manner occasion a profuse discharge of water, and so far may diminish the amount of liquid in the blood-vessels; but there is no reason to believe that it removes the "materies morbi," the "peccant matter," which constitutes the disease materially and essentially. If it were really curative in this manner, then jaborandi and pilocarpin ought to be the most efficient remedies for fevers and inflammations, which is not claimed in their behalf. What has been observed of its effects in acute rheumatism is true of other febrile diseases. As expressed by Boulter (*St. Bartholomew's Hosp. Rep.*, xv. 164), "Veratrum viride has little or no effect in reducing the temperature in rheumatic fever; the pains subside no more quickly (?) than under other ordinary modes of treatment; it has no power of warding off cardiac complications; and its only effect—which, however, only takes place in some cases—is to depress the vascular system, as shown by the slowness and irregularity of the heart's action." Cardiac sedatives, of which the medicine under consideration is the type, tend to retain in the blood all that is injurious in it, and at the same time reduce the patient to a state of such wretchedness that he is unable to take food, or to digest it if he ate it, or even to find energy enough to cling to that last refuge of sufferers, hope.

There is but one class of cases in which the utility of this medicine is presumable—cases of imminent or commencing congestion or inflammation, in which the maintenance of its sedative action on the heart for a short period would allow the conservative powers of the system to operate within normal limits. This statement applies to certain *wounds* which tend to dangerous results, like those of the head, pericardium and heart, and peritoneum. The comparative immobility in which the inflamed parts are maintained by the infrequent arterial movement may favor their cure. In some cases of organic *heart disease*, as well as of *nervous palpitation*, this medicine is reported to have afforded great relief, probably by allowing the heart sufficient rest for recovering its power. It would certainly be unsuited for the treatment of cardiac affections depending upon absolute debility of the organ. It has been used with alleged benefit in *puerperal mania*, *puerperal convulsions*, *epileptiform convulsions*, *chorea*, and *mania-à-potu*. In a case of persistent *priapism* affecting only the corpora cavernosa, and after failure to reduce it by means of many medicines, including tartar emetic, belladonna, and bromide of potassium, the penis began to be relaxed as soon as veratrum viride had reduced the pulse to 50 (Walker, *Am. Jour. Med. Sci.*, Apr.

1877, p. 565). It will be observed that nearly all of the affections in which the medicine has been most equivocally useful were marked by nervous, and not febrile, excitement; in other words, they were amenable to it as a sedative of the nervous and not of the circulatory system.

Externally, the tincture is used as a discutient and anodyne.

The proper remedies in poisoning by this drug are diffusible stimulants, and especially alcohol, which should be given by the rectum if the patient vomits. Its efficacy is shown by the case of a physician who took an ounce of the tincture at one draught; so completely did the alcohol counteract the green veratrum of the preparation that except nausea, vomiting, and some dyspnoea no evil results followed. Besides alcohol, ammonia may be administered, and sinapisms should be applied over the heart, while stimulant (that is, small and repeated) doses of some liquid preparation of opium may be administered. During the treatment the patient's head should be kept as low as his body, or even lower.

Administration.—Green veratrum may be administered in powder in the dose of 2 grains (Gm. 0.12), but the liquid preparations are more eligible. Of these the fluid extract and the tincture are official; the dose of the former is from 1 to 3 drops (Gm. 0.05–0.15), and of the latter from 4 to 8 drops (Gm. 0.20–0.40). They should be given at intervals of about three hours. Their tendency to cause vomiting may be prevented by the administration of from 5 to 10 drops of deodorized laudanum ten or fifteen minutes before each dose. As soon as the pulse begins to fall the dose should be diminished. Females and growing persons ought not to take doses exceeding two-thirds of those mentioned, and for children from one to five years old a sufficient quantity is 1 drop (Gm. 0.06) of the tincture. From 10 to 15 minims (Gm. 0.60–1) of the tincture, largely diluted with water, have been administered hypodermically.

VERBASCUM.—MULLEIN.

Flores verbasci, P. G.—*Bouillon-blanc*, Molène, Fr.; *Wollkraut*, Königskerze, G.

The leaves and flowers of *Verbascum Thapsus*, *Linné* (V. *Schraderi*, G. *Meyer*), *F. Cod.*; the corolla of *V. phlomoides*, *Linné*, and *V. thapsiforme*, *Schrader* (V. *Thapsus*, G. *Meyer*), P. G.

Nat. Ord.—*Scrophulariaceæ*.

Origin.—The genus *Verbascum* consists of tall, more or less woolly, biennial or perennial herbs, with the flowers in dense spikes or paniculate racemes. The flowers have a five-parted calyx, a wheel-shaped somewhat unequally five-lobed corolla, five more or less woolly stamens, and a two-celled, two-valved, and many-seeded capsule. Three species have been naturalized in North America—*Verb. Blattaria*, *Linné*, V. *Lychnitis*, *Linné*, and V. *Thapsus*, *Linné*, having the leaves respectively nearly smooth on both sides, tomentose on the lower surface, and densely woolly on both sides.

Description.—*Folia Verbasci*. The leaves are from 4 to 8 or 12 inches (10–20 or 30 Cm.) long, the upper ones sessile on the stem, and all decurrent. They vary in shape between elliptic, oblong, and oval-lanceolate, are acute, more or less crenate on the margin, and densely covered with soft whitish stellate hairs. The leaves are nearly inodorous and have an insipid, mucilaginous, faintly bitter taste.

Flores Verbasci. The calyx is rejected, and only the corolla with the adhering stamens is preserved. The wheel-shaped corolla is 1 to 1½ inches (25–37 Mm.) broad, bright-yellow, smooth above, and stellately tomentose beneath, has five obovate roundish lobes about ⅔ inch (15 Mm.) long, and bears in the short tube the stamens, of which the three upper ones have reniform anthers and the filaments covered with a white wool; the two lower stamens are longer and smooth and have elongated decurrent anthers. V. *Thapsus* has the corolla only about ½ inch (12 Mm.) broad, and the lower stamens with long filaments. V. *Lychnitis* and V. *Blattaria* have the anthers reniform upon equal filaments, which are white-woolly in the former and purple-woolly in the latter species. To preserve their bright color the flowers should be thoroughly dried and kept in a dry and well-stopped bottle; if permitted to become damp they acquire a blackish color. The flowers have a slight, agreeable, honey-like odor and a mucilaginous and sweet taste.

Constituents.—The leaves and flowers contain mucilage. Morin (1826) obtained from the flowers a trace of yellowish volatile oil, a fatty substance, sugar and coloring matter which is insoluble in ether and cold water and yields in alcoholic solution a yellow precipitate with acetate of lead.

Medical Action and Uses.—The chief medicinal constituent of this plant is the

mucilage furnished by its leaves, but its flowers contain an essential oil in small proportion, to which the agreeable odor of the fresh plant and its slightly stimulant qualities are due. Fish are said to become stupefied by eating the seeds. The infusion of mullein is useful in catarrhal affections of the *respiratory organs*, and in Ireland is in popular use to palliate *cough* and *diarrhœa*. For this purpose it should be boiled with milk. It is recommended in irritations of the *urinary bladder*. It may be used in enema for *dysentery*. A poultice made with the leaves boiled in milk is a convenient application to inflamed *hæmorrhoids*. Olive oil saturated with mullein-flowers during prolonged exposure to the sun, or kept near a fire for several days in a corked bottle, is a popular preparation in Germany for *bruises*, *frost-bite*, and irritable *piles*. The infusion should be made of the fresh leaves and flowers, if possible, in the proportion of an ounce to a pint (Gm. 32 to Gm. 500) of boiling water. When cool it should be strained to free it from the irritating hairs which cover the leaves.

VERONICA.—SPEEDWELL.

Véronique mâle, Fr.; *Ehrenpreis*, G.

Veronica officinalis, Linné.

Nat. Ord.—Scrophulariaceæ.

Origin and Description.—The common speedwell is distributed over a considerable portion of the northern hemisphere, and grows in grassy places and open woods. It is a procumbent pubescent perennial with ascending branches and with opposite, short-petiolate, obovate, or elliptic and coarsely crenate or serrate, grayish-green leaves, which are about an inch (25 Mm.) long. The flowers are in one or two axillary racemes on the upper part of the branches, are on short pedicels, and have a wheel-shaped four-parted pale-blue corolla with dark-blue stripes and two exserted stamens. The fruit is an inversely heart-shaped, two-celled capsule. The fresh herb is faintly aromatic; after drying it is inodorous and has a bitterish and slightly astringent taste.

Constituents.—Speedwell contains a little tannin and a bitter principle.

Allied Species.—VERONICA BECCABUNGA, Linné.—Brooklime, *E.*; Beccabunga, Cressonée, *Fr.*; Bachbungen, *G.*—It grows in Europe and Asia near springs and in brooks, and has an ascending smooth stem, with opposite, short-petiolate, oval or oblong, crenate-serrate, obtuse, and smooth leaves, about 1½ inches (38 Mm.) long, and with axillary loose racemes of pale-blue and veined flowers. It is used in the fresh state (*F. Cod.*).

VER. AMERICANA, Schucinitz, resembles the preceding, but has petiolate, ovate, acutish, and often slightly heart-shaped leaves.

Brooklime is inodorous, and has a bitterish, somewhat saline, and slightly pungent taste.

Medical Action and Uses.—Veronica is bitter, astringent, and slightly aromatic, in which qualities it resembles horehound and several other plants which, like it, have been used in the treatment of chronic *bronchitis*. Its decoction has been applied externally in *scabies*, papular *cutaneous eruptions*, and *ulcers*, and given internally in *urinary* and *calculous disorders*. *V. Beccabunga* is regarded as anti-scorbutic and diuretic, and is said to be slightly stimulant and tonic. It has been employed in chronic affections of the skin, in *scrofula*, and in *scurvy*, both internally and topically. It is reported that *V. parviflora* (*Koroniko*), a New Zealand plant, is very efficient in the treatment of chronic dysentery (*Practitioner*, xxix. 300).

VIBURNUM, U. S.—VIBURNUM (BLACK HAW).

The bark of *Viburnum prunifolium*, Linné.

Nat. Ord.—Caprifoliaceæ.

Origin.—The black haw is a tall shrub or small tree from 10 to 20 feet (3–6 M.) high, and grows in thickets throughout the greater portion of the United States east of the Mississippi. Its leaves are opposite, about 2 inches (5 Cm.) long, shining, oval or obovate, sharply serrulate, and have short slightly margined petioles. The small white pentamerous flowers are in terminal cymes, have a wheel-shaped corolla, and produce small blue-black edible drupes containing a flattish, smooth putamen. The bark is employed in medicine.

Description.—Black-haw bark is in thin quills, and has externally a somewhat glossy purplish-brown, and when older a grayish-brown, color. The surface is marked with scattered small roundish or transversely elongated warts, and often with minute black dots. The thin, papery, corky layer is easily removed from the green outer bark.

The inner bark is white and the inner surface smooth. The bark breaks with a short smooth fracture, is without odor, and has a slightly astringent and distinctly bitter taste.

Allied Species.—*VIBURNUM OBOVATUM*, *Walter*, grows in the Southern United States, and is a shrub about 8 feet (2.4 M.) high; it is also known as *black haw*. The leaves are $\frac{1}{2}$ to 1 inch (12–25 Mm.) long, rather leathery, broadly obovate or spatulate, narrowed into a short petiole, slightly revolute on the margin, either entire or crenate near the apex, and on the lower surface marked with minute brownish dots. The cymes are small and three-rayed, the flowers white, and the fruit black and ovoid-oblong. The leaves are inodorous and have a bitter taste, which is more persistent than that of the brown or reddish-gray bark.

VIBURNUM OPULUS, *Linné*.—Cranberry tree, *El.*; *Obier*, *Fr.*; *Wasserholder*, *G.*—It is a native of Canada, of the Northern United States, and of Europe and Northern Asia. It grows to a height of from 10 to 15 feet (3–4.5 M.), and has a gray or brown-gray bark, three-lobed serrate leaves, and white or yellowish-white flowers. The fruit is a bright-red, elliptic, one-seeded drupe resembling the cranberry. The brittle gray bark has a pungent taste, and is known as *cramp-bark*.

VIBURNUM LANTANA, *Linné*, is a European shrub with ovate or oval, slightly heart-shaped, acutely serrate leaves, and with red, finally black, mealy drupes of a mucilaginous and sweet taste. The inner bark is acrid.

Constituents.—The *viburnic acid* of Krämer (1844), obtained from the bark of the cranberry tree, was proved by Monro (1845) to be identical with valerianic acid. The *viburnin* of Krämer is a light-yellowish mass or whitish powder of a neutral reaction and of a purely bitter taste; it is slightly soluble in water and more freely soluble in alcohol. *Enz* (1863) found in the fruit of *V. lantana* a hygroscopic, neutral, bitter principle readily soluble in water; also valerianic, acetic, tartaric, and tannic acids. H. Van Allen examined black-haw bark, and obtained valerianic acid, viburnin, a resinous body of a very bitter taste containing sugar, tannin (greenish-black with ferric salts), and oxalic, citric, and malic acids. The air-dry bark contained 7 per cent. of moisture and yielded 8.3 per cent. of ash, consisting mostly of earth carbonates and phosphates.

Off. Prep.—*Extractum viburni fluidum*, *U. S.*

Medical Action and Uses.—Nothing definite appears to be known respecting the mode of action of this plant. Incongruous qualities are assigned to it, such as that it is at once nervine, astringent, diuretic, and tonic. The only medicinal operation attributed to it does not involve any of these operations—viz. a power of preventing *abortion*, particularly when attempted by the use of cotton-root. A case intended to illustrate such virtue in the drug has been published (*Therapeutic Gaz.*, Nov. 1882), but as the patient also took enormous doses of morphine, as well as bromide of potassium, it is impossible to believe that the viburnum had any share in the result. At a meeting of the *Materia Medica Society of New York* (1883) the value of this drug was discussed, and no conclusive evidence of its alleged virtues was adduced. On the same occasion the use of *V. Opulus* was urgently advocated as a very efficient anti-spasmodic in asthma, hysteria, puerperal and other convulsions, and as “a powerful uterine sedative” (*Med. Record*, xxiii. 188). In 1876 another physician described it as “a uterine sedative, and often a remedy for neuralgic *dysmenorrhœa* and for the commonly associated spinal irritation.” Indeed, it has been credited with increasing, and also with diminishing, the menstrual flow. The medicine seems to be worthy of a rational study. Viburnum has been administered in the form of an infusion or a decoction made with an ounce of the bark to a pint (Gm. 32 in Gm. 500) of water, and in doses of 1 or 2 ounces (Gm. 32–64), repeated every two or three hours. The official fluid extract may be given in doses of from $\frac{1}{2}$ to 2 fluidrachms (Gm. 2.00–8).

VINA MEDICATA.—MEDICATED WINES.

Vins médicinaux, *Ænolés*, *Fr.*; *Medicinische Weine*, *G.*

Medicated wines are preparations analogous to tinctures, but differ from them in the menstruum, which contains a much smaller and a somewhat variable quantity of alcohol and a certain proportion of extractive matter and bitartrate of potassium. The menstruum directed for the medicated wines is either dry white wine (*F. Cod.*, *P. G.*), a mixture of white wine and alcohol (*U. S.*, *F. Cod.*), sherry wine (*Br.*, *P. G.*), or red, Lunel, Grenache, Malaga, and other wines (*F. Cod.*). Since even the strongly alcoholic official wines cannot be kept unaltered for an indefinite period if exposed to the air, the medicated wines,

which necessarily contain various principles subject to gradual decomposition, should be kept in well-stopped bottles.

VINUM ALBUM, U. S.—WHITE WINE.

Vinum generosum album, P. G.—*Vin blanc*, Fr.; *Weisswein*, G.

The fermented juice of the fruit of different species of *Vitis*.

Nat. Ord.—Vitaceæ.

Origin.—American wines are mostly obtained from the fruit of cultivated varieties of *Vitis Labrusca*, *Linne*, and more particularly from Catawba, Concord, and Isabella grapes. The Clinton grape is a variety of *V. aestivalis*, *Michaux*; the Delaware grape is derived from *V. cordifolia* or *V. riparia*, *Michaux*; and the Scuppernong grape from *V. vulpina*, *Linne*. The European grape was introduced into California at an early period, and large quantities of wine are now manufactured from the different varieties. All European wines are prepared from the fruit of *Vitis vinifera*, *Linne* (see UVÆ), which is a native of Western Asia and has been cultivated for many centuries; it is not unlikely that this species originated from two or three different plants, supposed by some botanists to be indigenous to India, and by others to be still found in the wild state in Eastern countries and in Southern and Central Europe.

Manufacture of Wine.—In addition to the constituents of grapes enumerated under UVÆ, vegetable albumen, glutinous matter, pectin, and various extractive matters are found in the juice of grapes, and occasionally racemic acid, either in the free state or partly combined with bases. Besides tartrates, the saline constituents are sulphate of potassium, chloride of sodium, phosphate of calcium, magnesia, alumina, and silica. The relative amount of these principles varies considerably, depending on the nature of the soil and on atmospheric conditions during the growth and ripening of the fruit, when the free acid is gradually diminished and the sugar considerably augmented in quantity. The sugar varies in amount between 12 and 30 per cent., the larger quantity being produced in warm climates. It is obvious from this that the treatment of the grape-juice for the production of wine must vary under different circumstances and in different countries. The grapes are either crushed and the juice fermented in the presence of the husks, or the juice, called *must*, is fermented by itself, in which case a light-colored wine is obtained. Red wines are made by fermenting with husks and seeds, called the *marc*, of red or purple grapes. In a short time after the must has been pressed, fermentation commences, and continues for two or three weeks, when the liquid becomes somewhat clear, and is removed from the precipitate into another vessel, where a slow fermentation, called the *after-fermentation*, proceeds for several weeks or months, requiring the occasional removal of the liquid from the sediment formed, until it is fit to be transferred into casks, where it is allowed to “ripen.” The best wines are usually bottled some time after they have become perfectly clear, the complete clarification being effected by gelatin, which, in combining with the tannin present, forms an insoluble compound, carrying down with it all traces of yeast and other matters held in suspension. The “bouquet” of wine is much improved after bottling, and red wines, which do not contain a large amount of tannin, become darker, while wines rich in tannin form a deposit in the bottle and become lighter in color.

The conditions under which fermentation takes place, and the results, are explained on page 140. In the presence of the numerous constituents of grapes odorous principles are generated during fermentation to which wines owe their peculiar aroma or bouquet. If the must contains a moderate quantity of sugar, this is entirely or nearly decomposed into alcohol and carbonic acid, resulting in a *dry wine*. But in a strongly saccharine must fermentation ceases before the sugar is completely consumed, and the product is a *sweet wine* (*vin de liqueur*, *Fr.*). In some cases the amount of sugar in the juice is increased by exposing the cut ripe grapes for some time to the sun until a portion of the water has evaporated, or by concentrating a portion of the juice before fermentation. As the alcohol increases during the fermentation of the must, the acid tartrate of potassium becomes less soluble and is gradually deposited, the deposition continuing for some time after the storing of the wine in casks.

If wine is bottled before it has undergone the after-fermentation, a *sparkling wine* will be obtained. The fermentation will slowly proceed in the bottle, which is placed upside down, so that the precipitate which forms may settle in the neck, and may be finally withdrawn by carefully removing the stopper and quickly replacing it. The effervescence of sparkling wines is produced by the carbonic acid confined in the bottle.

Improving.—This term is used to include all those manipulations designed to preserve wine or render it more pleasing in appearance and taste by the addition of alcohol, glycerin, coloring matters, sugar, and other substances. In many cases so-called improving must be considered to be merely adulteration; but from the natural variation of the composition of grape-juice it is sometimes desirable to correct an excess or deficiency of one or more constituents, and for this purpose the following processes have been suggested:

1. Gypsum is largely employed in some parts of Europe as an addition to the must, for the purpose of hastening the clarification of wine, which then contains potassium sulphate in the place of bitartrate.

2. Chaptal (1800) proposed the removal of excessive acidity by marble and the addition of sugar to the must.

3. Gall proposed to correct excessive acidity by the addition to the must of sugar and water, whereby, evidently, an acid grape-juice is made to yield a correspondingly larger amount of wine.

4. Petiot (1859) suggested the utilization of the marc left on expressing the must, by fermenting with it a solution of sugar, the product being either sold as wine or mixed with other wines.

5. Liebig (1848) suggested the removal of free acid by the addition of a concentrated solution of potassium tartrate in such proportion as to form bitartrate, which will be deposited from the wine.

6. To render weak wines stronger without foreign additions, Melsens (1873) introduced the freezing process, whereby a portion of the water is removed in the form of ice.

7. Pasteur's method consists in the heating of wine to from 50° to 65° C. (122°–149° F.), air being excluded, for the purpose of destroying fungoid germs and rendering the wine more permanent.

Properties.—As a class, white wines are distinguished from red wines by the absence of red coloring matter and of notable quantities of tannin, though minute proportions of this compound are usually present. They are never colorless, but vary in shade between pale-yellow and deep-amber color.

Sherry wine (Vinum Xericum, *U. S.* 1870, *Br.*; V. Xerense, *P. G.* 1872) has a rather deep-amber color, an agreeable vinous odor, and a warm and very slightly acid taste. We found (1886) its specific gravity to range between .978 and .995, and its average alcoholic strength to be 20.34 volumetric per cent.; the sugar and extractive averaged 3.27 (highest 5.3) per cent. in 67 samples examined. Similar wines are produced in various parts of Spain, Portugal, the Canaries, and Madeira, several of which are met with in our commerce. *Lisbon wine* has a density of about .990, and contains 19 or 20 per cent. of alcohol. *Teneriffe wine* closely resembles the preceding in properties. A stronger wine is *Madeira wine*, which usually contains between 19 and 22 per cent. of alcohol; it has a different somewhat nutty flavor.

Wines of similar strength in alcohol are also made in Italy (*Marsala*), Greece (*vin santo*), and the Cape Colony (*Constantia*). Southern France produces wines containing 14 to 16 per cent. of alcohol, of which those of *Lund* and *Grenache* are ordered by the Codex. *Burgundy* wines are of about the same strength. Very sweet wines, rich in alcohol, are, among others, *Tokay* (Hungary), *Lachrymæ Christi* (Italy), and *Malaga* (Spain).

The white *Rhenish wines* are known here as *hock* (from *Hochheimer*). They have a more acidulous taste than the preceding wines, from the presence of acid tartrate of potassium and the nearly total absence of sugar. They are of a pale-yellow color, and usually contain between 8 and 10 per cent. of alcohol. *Moselle wine* is nearly of the same strength. The *French wines*, both white and red, are required to contain about 10 per cent. of alcohol (*F. Cod.*).

The white wines of the Mississippi and Ohio Valley and the *California wines* resemble the wines of Central and Southern Europe in appearance, flavor, and alcoholic strength; the weaker varieties of the latter, which are known as *California hock*, have not the fine bouquet of the better qualities of Rhenish wines, but the quality of American wines has considerably improved of late years.

The sparkling *champagne wines* contain between 10 and 12 per cent. of alcohol.

Constituents.—The principal constituents of all wines are water and alcohol. The amount of the latter present in different wines has been given above. The acidulous taste of wine is due to *acid tartrate of potassium*, and small quantities of *acetic acid* are

met with in old wines, resulting from the spontaneous oxidation of alcohol. A somewhat larger proportion of acetic acid is usually present in the wine of the Eastern section of the United States. The amount of *sugar* varies considerably; while the weaker dry wines contain none or but very little, it is found in sherry to the extent of from 1 to 5 per cent., increases in champagne sometimes to 5 or 6 per cent., in port wine to 6 or 7 per cent., and in the sweet wines, like *Malmsey Madeira*, to 11 or 15 per cent. or more. The "body" of wine has been ascribed by Fauré to a principle which he named *œnanthin*, and which is probably of the nature of gum or dextrin. *Tannin* seems to be present in all wines—in minute proportion in the white, and in larger proportion in the red wines. The *coloring matter* of wine varies for causes stated above; the color of red grapes is not soluble in water, but is extracted during fermentation as the alcohol increases. The *aroma* of wine is doubtless due to the presence of various compound ethers formed in the juice while fermenting. These exist in very minute quantities, and have for this reason not been accurately examined; but the following have been stated to contribute to the aromatic odor of wine: acetic, butyric, caprylic, caproic, œnanthic, pelargonic, capric, and propionic ethers, besides aldehyd, acetal, and probably other compounds. The inorganic constituents of wine are the same as those of grape-juice, except that tartrate of calcium and the greater portion of acid tartrate of potassium have been deposited; the ash varies between about .1 and .5 per cent.

The U. S. Pharmacopœia not only permits, but evidently encourages, the use of native wines, provided they be pure and contain between 10 and 12 per cent. by weight of absolute alcohol. From causes explained before, the composition of wines made from the same variety of grape grown in different localities, or from different vintages in the same locality, must be expected to vary to some extent; every quantitative analysis of wine, therefore, refers only to the sample examined. A large number of American wines have been analyzed by Prof. H. B. Parsons, which, classified in principal groups, show the following results for 100 parts of white wines:

	51 Dry Wines.			7 Sherry Wines.			22 Sweet Catawba, Angelica, etc.			15 Sparkling Wines.		
	Average.	Highest.	Lowest.	Average.	Highest.	Lowest.	Average.	Highest.	Lowest.	Average.	Highest.	Lowest.

One sweet wine (Muscatel) contained 25.37 per cent. of glucose and 31.34 per cent. of total residue.

Changes.—Like other weak alcoholic liquids, wine is apt to undergo acetic fermentation, which is prevented by excluding atmospheric oxygen. Mucous fermentation causes wine to become ropy; white wines are subject to this change more than red wines, caused by the presence of insufficient tannin in the must for precipitating all the albuminoids. Some wines, like Burgundy, are liable to acquire a bitter taste, and occasionally wine becomes mouldy. Scrupulous cleanliness of the vessels in which wine is kept and exclusion of air will prevent most of these changes.

Tests.—With the exception of the U. S. P., none of the pharmacopœias give any tests for determining the quality of wine, which is directed to be ascertained as follows: "White wine should have a full, fruity, agreeable (and red wine a moderately astringent) taste, without excessive sweetness or acidity (red wine without decided sweetness or excessive acidity), and it should have a pleasant odor, free from yeastiness. Its sp. gr. at 15.6° C. (60° F.) should not be less than 0.990 (red wine .989) nor more than 1.010. If 10 Ccm. of white wine be diluted with an equal volume of distilled water and treated with 5 drops of test solution of ferric chloride, only a faint, greenish-brown color should make its appearance (absence of tannic acid) (with red wine the liquid should acquire a

brownish-green color, due to tannic acid). Upon evaporation and 12 hours' drying on the water-bath it should leave a residue of not less than 1.5 per cent. nor more than 3.0 per cent. (red wine between 1.6 and 3.5 per cent.). Using litmus-paper as an indicator, 250 Ccm. of white wine should require for complete neutralization not less than 15 nor more than 26 Ccm. of the volumetric solution of soda. Tested by the following method, white (and red) wine should contain not less than 10 per cent. nor more than 12 per cent., by weight, of absolute alcohol: Weigh a definite volume of the wine at the temperature of 15.6° C. (60° F.); evaporate it in a porcelain capsule to one-third of its original volume, cool, and add distilled water until the mixture measures its original volume at the temperature of 15.6° C. (60° F.); then weigh again. The first weight divided by the second will afford a quotient (to be carried out to four decimal places) which corresponds to the percentage of absolute alcohol, by weight, in the wine."—*U. S.*

Aside from the coloring matter, the requirements and tests of the Pharmacopœia are alike for white and red wine, with slight modifications for the latter, as indicated above. Wines from fruits other than the grape, and artificial or sophisticated wines, may correspond closely with the above requirements. For the detection of such the following brief summary from the observations of Prof. Nessler will be useful: By far the largest number of dry grape-wines contain between 1.6 and 2.2 per cent. of *solid matter*; this is conveniently estimated by evaporating the alcohol and diluting the residue with water to the original volume, when the liquid should have the specific gravity 1.007 or 1.008, and should not be less than 1.005. Grape-wines contain no *citric acid* and little or no free *tartaric acid*. The latter is best detected by agitating the wine with powdered potassium bitartrate until saturated, and adding to the filtrate potassium acetate, when in the presence of free tartaric acid a precipitate will be produced. Most pure wines yield a precipitate with tartaric acid, proving the presence of potassium salts other than bitartrate. To detect citric acid add to the wine an excess of lime, filter, acidulate with acetic acid, add excess of barium chloride, filter from the barium sulphate, and add excess of ammonia, when barium citrate will be precipitated. For the detection of free sulphuric acid strips of filtering-paper about 12 inches (30 Cm.) long are suspended in such a manner that the lower end dips into the wine, which is gradually absorbed and evaporates from the upper part, where the extractive matters and sulphuric acid become more concentrated; after 24 hours the paper is carefully dried, and then heated to 100° C. (212° F.), when the portion charged with extractive becomes brown or black and frequently brittle from the free sulphuric acid, the reaction being more delicate in the presence of 0.1 or 0.2 per cent. of sugar. The brown-yellow *coloring matter* of wine containing a little tannin is precipitated on agitation with egg albumen, while the color produced by caramel is not altered.

Winckler stated that cider and other fruit-wines contain lactic acid and calcium lactate, which are not found in grape-wine. Tuschmid (1870) found the amount of carbonate of calcium obtainable in the ashes of grape-wine never to exceed 0.049 per cent., while other fruit-wines yield between 0.11 and 0.40 per cent. of the same salt. The amount of sulphates in wine varies in most cases, so as to represent between .01 and .03 per cent. of sulphuric acid; Nessler found occasionally .11 per cent. Wines treated with gypsum contain a larger quantity.

The determination of alcohol is usually effected by one of the two following methods: A definite quantity of wine is distilled by means of a water-bath until one-half of the liquid has passed over; the distillate is diluted with distilled water to the original volume or weight of the wine, when its specific gravity indicates the alcoholic strength; or, the residue in the still is diluted with water to the original volume or weight of the wine; its specific gravity is now ascertained, and from this figure is deducted the specific gravity of the wine; the difference, representing the solid constituents, is deducted from 1.000 (density of water), and the figure thus obtained gives the density of the alcohol present. The method adopted by the Pharmacopœia is a modification of the last one described, and was suggested by Prof. Parsons. A number of instruments have been constructed by means of which the alcoholic strength may be determined either from the pressure or the heat of the vapors of the boiling liquid; volatile acids, if present, must be previously neutralized.

History.—The dietetic history of wine is almost coeval with that of the human race, for all the countries inhabited by nations whose remote history has come down to us abound in grapes, and the first sin committed after the Deluge was drunkenness. Its medicinal virtues were treated of by Hippocrates, Galen, Pliny, and the Arabian physicians. The last described in full detail the consequences of its excessive use,

which, indeed, had already been done by Jewish as well as Roman writers. They are essentially those which have been enumerated in the article on ALCOHOL. Nevertheless, it would be a grave error to conclude that a given quantity of wine is equivalent to an equal quantity of water containing a like percentage of alcohol. The peculiar effects of a true wine depend upon its ethereal and saline elements, its sugar, tannic acid, etc., which modify materially those which would be produced by its alcohol alone. The true medicinal effects of wine are to be sought in the products of the vineyards of continental Europe and a few other places. Those of our own country have not yet attained such a degree of perfection as to enable them to compete with the better class of foreign wines, yet even in their comparatively crude state they are probably less mischievous than distilled spirits, provided they can be obtained pure. Improvement in their manufacture, by rendering them generally acceptable, would not only confer a priceless boon upon the sick, but would provide even for the drunkard a potation less injurious to himself than alcohol, and save the commonwealth from a large proportion of the infamous crimes which disgrace our civilization, and from the physical deterioration which threatens to produce national decrepitude. In France, drunkenness, as it is known in this country and in the north of Europe, was comparatively rare as long as wine and cider were the only alcoholic beverages in general use; but the vice has greatly extended of late years, and its increase has been mainly in the cider-drinking departments, where alcohol distilled from grain is largely used, because it is more accessible than wine. In the wine-growing districts, where brandy of a less injurious quality is made, the use of the latter beverage is comparatively small; and in the departments where wine is not produced the cases of drunkenness requiring legal action are five times greater than in those which consume wine principally. In like manner, the proportion of cases of insanity originating in alcoholic drinks is in direct proportion to the use of distilled spirits, and especially of those which are not procured from wine.

Physiological Action.—Wine, including all forms of genuine wine, is essentially a stimulant of the nervous and circulatory systems, but its mode of stimulation is unlike that of mere alcohol. In due proportion it gives to all the faculties increased activity and freedom of action, quickening and brightening the intellect and the imagination, warming the feelings, invigorating the digestive powers, and diffusing a cordial satisfaction throughout the whole being. Distilled spirits, on the other hand, tend to benumb the faculties even while stimulating them, so that they seem to be struggling under a brute force; the exhilaration they produce is usually fierce or maudlin, and they leave behind them a dull and inert dejection. As already stated, the peculiar effects of wine are due to the salts, acids, sugar, and, above all, the ethereal elements, in which it abounds, and which, while they tend to mitigate the anæsthesia produced by the alcohol of the liquid, ensure a more rapid discharge of this substance from the system. The white wines, as a class, are distinguished by the rapidity with which they exhilarate and intoxicate, as well as by the relatively transient character of the excitement they produce, and by their marked diuretic action. Most of the red wines, and especially port wine, contain a portion of tannin, which retards their absorption, and therefore lessens their immediate stimulant effects. They are, on the other hand, more or less tonic, and hence become well adapted to the convalescent stages of acute disease and to states of chronic debility. (See VINUM RUBRUM.) The effects of wine in excessive doses resemble more nearly those produced by distilled spirits, yet even then they are less extreme and debasing. Its habitual use is conducive to the health of those who drink it in moderation, and is the best corrective of the brutality and preventive of the crime which everywhere attend the consumption of ardent spirits. The very quantity of it required to produce intoxication tends to limit the mischiefs of its inordinate use; and even when "the sweet poison of the misused wine" is indulged in beyond measure, its mischievous influence upon the health is less than that of alcohol, for, while the latter tends directly to occasion fatal disease of the liver, heart, and kidneys, the intemperate use of wine is more apt to engender gout, gravel, and nervous affections. Even these results are rarely attributable to some of the wines which are most largely used, as the Rhenish, Bordeaux, and most Italian wines, both white and red.

Medical Uses.—Wine is employed in the treatment of the same forms of disease for which distilled alcohol is appropriate, but, according to general usage, in the less grave forms, and for women, children, and old persons rather than for adult men. The clearest indication for its use is furnished by *adynamic fevers*, and most of all typhus fever, a disease in which enormous quantities of wine have sometimes been administered with the most salutary results. In a less degree it is useful in *typhoid fever* and in all

febrile affections which assume the *typhoid state*, provided that symptoms of the following character are present: viz. prostration, wandering, delirium, petechiæ, stupor, and brown tongue; feebleness, irregularity, dicrotism or softness of the pulse; and particularly feebleness or absence of the first sound of the heart. When delirium, unconsciousness, and dryness of the tongue have been succeeded by a state of exhaustion, languor, and debility, with imperfect sleep and anorexia, the cordial operation of wine is a precious help toward the cure. But it is as true of wine as of distilled spirits, that the necessity for it is often more apparent than real, and that a premature and excessive use of it renders the patient insensible to its operation when it has become essential to his recovery. We have never had such good reason to be pleased with the results of treatment in typhoid fever as when in a large hospital service the use of alcohol in this disease was almost wholly omitted.

During *convalescence* from many diseases wine taken with food is often a potent aid to recovery, and it is often also of essential utility in chronic affections which waste the strength by profuse *discharges* or by *pain* or by inducing an *anæmic* condition. In all of these cases red wines are more efficacious than white. The latter, however, and in general the more stimulating wines, are best adapted to cases in which a speedy but transient influence is intended, as where *syncope* is imminent or the patient is reviving from it after powerful nervous shocks, exhausting fatigue of body or mind, severe pain, hæmorrhage, etc., and in cases of debility of the heart arising from structural alterations in it. In the milder forms of *delirium tremens*, especially as they occur in females, and notably in those of the better classes, wine is greatly to be preferred to distilled spirits. In some minor *spasmodic affections*, as the *vomiting* of pregnancy or of sea-sickness, the sparkling wines are often of great service. Infantile reflex *convulsions* may frequently be prevented or mitigated by a timely dose of wine administered by the rectum or the mouth. It is equally efficient in all other affections in which danger arises from debility and its immediate consequences, and among them *capillary bronchitis* may be particularly noted. *Tetanus* has been successfully treated by wine, and the depressing action of *tobacco* and other sedatives of the heart and nervous system may be counteracted by its means.

It seems superfluous to say a word of the special virtues of sherry wine, since it is almost impossible to procure any of it which is pure and presents that peculiar "nutty" flavor, and that "dryness," or slight acidity, which at one time were characteristic of this wine, and which rendered it a valuable cordial in exhaustion of the nervous system and of the heart and a wholesome aid to feeble digestion. In England, where, more than elsewhere, it was generally used by the better classes, it was regarded as especially appropriate for dyspeptic, gouty, and rheumatic invalids. At present those who prescribe "sherry wine" should know that there is seldom any wine in the liquid at all, but that it consists usually of alcohol, water, and flavoring ingredients. It is far better to use medicinally whiskey made from wheat or rye, which there is less temptation for the dishonest dealer to adulterate, than the mischievous compounds sold under the name of sherry. Sherry is less astringent, and, according to some analyses, slightly less, and according to others slightly more, alcoholic than port. Commercial sherry wine is less suited than pure wine for making *wine whey*, which is prepared by adding the wine to milk at the boiling temperature, in the proportion of from 2 to 8 fluidounces of the former to a pint of the latter, straining off the whey and sweetening it. It is a mild and slightly nutritious stimulant much used in cases of debility from exhaustion and in the *typhoid state*. Wine diluted with water may be given by enema with scarcely less advantage than by the stomach. (For a fuller description and history of wines the reader is referred to *STILLÉ, Therapeutics*, 4th ed., ii. 710.)

VINUM ALBUM FORTIUS, U. S.—STRONGER WHITE WINE.

Preparation.—White Wine 7 parts (42 oz. av. or about 40½ fluidounces); Alcohol 1 part (6 oz. av. or 7 fluidounces); mix them.—U. S.

This wine is used as the menstruum for preparing the various medicated wines of the present Pharmacopœia, which become reasonably permanent and little liable to undergo acetous fermentation in consequence of the increase of the alcoholic strength. If the materials used are of pharmacopœial strength, the mixture will contain between 20 and 22 per cent. of absolute alcohol; the Pharmacopœia permits a variation of between 20 and 25 per cent. if tested in the manner described under VINUM ALBUM.

VINUM ALOES, U. S., Br.—WINE OF ALOES.

Vinum aloeticum.—*Vin (Enolé) aloétique*, Fr.; *Alowein*, G.

Preparation.—Purified Aloes 6 parts ($1\frac{1}{2}$ oz. av.); Cardamom 1 part ($\frac{1}{4}$ oz. av.); Ginger 1 part ($\frac{1}{4}$ oz. av.); Stronger White Wine a sufficient quantity; to make 100 parts (25 oz. av.). Mix the aloes, cardamom, and ginger, and reduce them to a moderately coarse (No. 40) powder. Macerate the powder with 90 parts ($22\frac{1}{2}$ oz. av. or 22 fluidounces) of stronger white wine for 7 days, with occasional agitation, and filter through paper, adding, through the filter, enough stronger white wine to make the filtered liquid weigh 100 parts (25 oz. av. or about 24 fluidounces).—*U. S.*

Socotrine aloes $1\frac{1}{2}$ oz. av.; cardamom-seeds, freed from the pericarps and bruised, ginger, in coarse powder, each 80 grains; sherry sufficient to make 2 pints.—*Br.*

Medical Uses.—This preparation is rarely used, because, like all liquid preparations of aloes, its taste is repulsive, and the pilular forms of the medicine are therefore more acceptable. Yet it probably has the advantage over them of being already a solution, and therefore of acting in a relatively smaller dose than aloes itself. It is useful in cases of habitual constipation from torpor of the colon and rectum, especially when associated with flatulent dyspepsia, gout, or amenorrhœa. *Dose*, as a laxative, about half a fluidounce (Gm. 16).

VINUM ANTIMONII, U. S.—WINE OF ANTIMONY.

Vinum antimoniale, Br.; *Vinum stibiatum*, s. *emeticum*, P. G.—*Antimonial wine*, E.; *Vin émétique*, *Vin antimonié*, *Vin stibié*, Fr.; *Brechwein*, G.

Preparation.—Tartrate of Antimony and Potassium 4 parts (30 grains); Boiling Distilled Water 60 parts (450 grains or 1 fluidounce); Stronger White Wine a sufficient quantity; to make 1000 parts (7500 grains = $17\frac{1}{4}$ oz. av.). Dissolve the tartrate of antimony and potassium in the water, and, while the solution is hot, add 600 parts (4500 grains or $10\frac{1}{8}$ fluidounces) of stronger white wine, and filter through paper, adding, through the filter, enough stronger white wine to make the filtered liquid weigh 1000 parts ($17\frac{1}{8}$ oz. av. or about 16 fluidounces).—*U. S.*

Nearly the same proportions are the following: Tartarated antimony 40 grains; sherry 1 pint (Imperial).—*Br.* Tartar emetic 1 part; sherry 250 parts.—*P. G.*

If made with good wine and judiciously preserved, antimonial wine will keep unaltered for a long time.

Off. Prep.—*Mistura glycyrrhizæ comp.*, *U. S.*

Medical Uses.—The chief value of antimonial wine consists in its being a convenient addition to febrifuge solutions, and especially in association with a liquid preparation of opium and spirit of nitrous ether. In such combinations it greatly promotes the diaphoresis which is a natural crisis of fever. The direct sedatives of the heart have no such salutary operation. In like manner it may be added to mixtures for promoting expectoration in febrile affections of the air-passages, as in the official compound liquorice mixture. It should seldom be used as an emetic, for its action in children is too depressing, and for adults the necessary dose of it is such that the stimulant action of the wine counteracts the sedative or nauseant operation of the antimonial. As a febrifuge and expectorant the *dose* of antimonial wine is about 10 drops (Gm. 0.60), repeated at longer or shorter intervals, according to its effects. This dose is preferable to the larger ones generally recommended.

VINUM AROMATICUM, U. S., F. Cod.—AROMATIC WINE.

Vin (Enolé) aromatique, Fr.; *Kräuterwein*, G.

Preparation.—Lavender 1 part ($\frac{1}{4}$ oz. av.); Origanum 1 part ($\frac{1}{4}$ oz. av.); Peppermint 1 part ($\frac{1}{4}$ oz. av.); Rosemary 1 part ($\frac{1}{4}$ oz. av.); Sage 1 part ($\frac{1}{4}$ oz. av.); Wormwood 1 part ($\frac{1}{4}$ oz. av.); Stronger White Wine a sufficient quantity; to make 100 parts (25 oz. av.). Mix the solid ingredients, and reduce them to a coarse (No. 20) powder. Moisten the powder with 4 parts (1 oz.) of stronger white wine, pack it moderately in a conical glass percolator, and gradually pour enough stronger white wine upon it to make the filtered liquid weigh 100 parts (25 oz. av. or about 24 fluidounces).—*U. S.*

This is equivalent to the preparation, somewhat simplified, of the old French Codex. The present Codex orders vulnerary tincture 1 part, red wine 7 parts.

TINCTURA VULNERARIA, Alcoolature (Teinture) vulnéraire, *F. Cod.*, is made by mace-

rating 100 Gm. each of the fresh leaves and tops of eighteen plants, including the six of the above formula, and 3000 Gm. of alcohol sp. gr. .863.

Action and Uses.—Aromatic wine is designed for topical purposes only. It represents a class of preparations which were formerly in common use as vulneraries, either as applications to recent wounds or to stimulate indolent ulcers. An almost identical preparation was used by Ricord as a dressing for chancres, and is now officinal in France. It is applied on charpie.

VINUM AURANTII, Br.—ORANGE WINE.

Wine made in Britain by the fermentation of a saccharine solution to which the fresh peel of the bitter orange has been added.—*Br.*

It is a vinous liquid, having a golden-sherry color and a taste and aroma derived from the bitter orange-peel. It contains about 12 per cent. of alcohol, and is but slightly acid to test-paper.

Off. Prep.—Vinum ferri citratis, Vinum quiniæ, *Br.*

Medical Uses.—Orange wine is used exclusively as a flavoring ingredient of mixtures and as an excipient in certain British officinal preparations.

VINUM COLCHICI RADICIS, U. S.—WINE OF COLCHICUM-ROOT.

Vinum colchici, Br.; *Vinum de colchico*, F. Cod.—*Vin (Eucolé) de bulbe de colchique*, Fr.; *Zeülosenknollenwein*, G.

Preparation.—Colchicum-Root, in No. 30 powder, 40 parts (10 oz. av.); Stronger White Wine a sufficient quantity; to make 100 parts (25 oz. av.). Moisten the powder with 10 parts of stronger white wine, pack it moderately in a conical percolator, and gradually pour enough stronger white wine upon it to make the filtered liquid weigh 100 parts (25 oz. av. or about 24 fluidounces).—*U. S.*

Colchicum, sliced, dried, and bruised, 4 oz. av.; sherry sufficient to make 1 pint (Imperial).—*Br.* Fresh colchicum-root 100 Gm., strong wine (vin de Grenache) 1000 Gm.—*F. Cod.*

This preparation is recognized in Great Britain as *wine of colchicum*, under which name in the United States the wine of colchicum-seeds is usually understood. Owing to the deterioration of colchicum-tuber when long kept, the preparation is apt to be deficient in strength, since the drug cannot be at all times obtained fresh or recently dried. The first formula yields a preparation of about the same strength as that of the U. S. P. 1870.

Medical Uses.—This preparation, which is believed to possess all the virtues of colchicum, may be prescribed in *doses* of 10 minims (Gm. 0.60), and gradually increased.

VINUM COLCHICI SEMINIS, U. S.—WINE OF COLCHICUM-SEED.

Vinum colchici, P. G.—*Vin (Eucolé) de semence de colchique*, Fr.; *Zeülosenamenwein*, G.

Preparation.—Colchicum-Seed, in No. 20 powder, 15 parts (3½ oz. av.); Stronger White Wine a sufficient quantity; to make 100 parts (25 oz. av.). To the powder add 90 parts (22½ oz. av.) of stronger white wine, and macerate for 7 days, with occasional agitation; then filter through paper, adding, through the filter, enough stronger white wine to make the filtered liquid weigh 100 parts (25 oz. av. or about 24 fluidounces).—*U. S.* 5 oz. av. of seeds yield about 32 fluidounces of this wine.

Bruised colchicum-seed 60 Gm., strong wine 1000 Gm.—*F. Cod.* Coarsely powdered colchicum-seed 1 part, sherry wine 10 parts.—*P. G.*

In order to extract the colchicine the seeds require to be well bruised. By passing them several times through a good drug-mill, regulating at the same time the grinding surface, they may be obtained of a sufficiently fine powder. If a suitable mill is not at hand, they should be macerated in a portion of the wine for several days, and be bruised in a mortar while damp. None of the pharmacopœias permit digestion of the unbroken seeds. 10 parts *U. S.* are equal to 15 parts *P. G.* and 25 parts *F. Cod.* of this wine.

Medical Uses.—The commencing *dose* is about half a fluidrachm (Gm. 2).

VINUM ERGOTÆ, U. S.—WINE OF ERGOT.

Vin de seigle ergoté, Fr.; *Mutterkornwein*, G.

Preparation.—Ergot, recently ground and in No. 30 powder, 15 parts (3½ oz. av.); Stronger White Wine a sufficient quantity; to make 100 parts (25 oz. av.). Moisten the

powder with 4 parts (1 oz. av.) of stronger white wine, pack it moderately in a cylindrical percolator, and gradually pour enough stronger white wine upon it to make the filtered liquid weigh 100 parts (25 oz. av. or about 24 fluidounces).—*U. S.* 5 oz. av. of ergot are contained in about 2 pints of the wine.

This preparation is about 14 per cent. stronger than that of the *U. S. P.* 1870. The manipulation is similar to that of the *U. S. P.* 1860. By paying proper attention to the quality of the ergot and to the directions given above, an efficient preparation will be obtained. The same must be said if a properly-prepared fluid extract, made from good ergot, is used, as was directed by the last Pharmacopœia; in our experience the latter represents ergot even better than the vinous percolate.

Medical Uses.—The wine is less frequently employed than other preparations of ergot, but may be prescribed in *doses* of from 1 to 3 fluidrachms (*Gm.* 4–12).

VINUM FERRI, *Br.*—WINE OF IRON.

Vinum chalybeatum, s. martiatum.—*Vin chalybé, Fr.*; *Eisenwein, Stahlwein, G.*

Preparation.—Take of Fine Iron Wire (about No. 35) 1 ounce; Sherry 1 pint. Macerate for 30 days in a closed vessel, the iron being almost, but not quite, wholly immersed in the wine, the vessel frequently shaken, and the stopper removed; then filter.—*Br.*

The acid tartrate of potassium dissolves the iron, with the evolution of hydrogen, resulting in the formation of ferrous tartrate or of its double salt with potassium tartrate. Owing to the variable acidity of different wines, and to the necessarily variable composition of this preparation, it has very properly been discarded by most pharmacopœias, or has been replaced by one of more definite strength in iron, like the wine of citrate of iron.

Medical Uses.—This preparation is one of the mildest of ferruginous medicines. It is, however, quite as well prepared extemporaneously by making a solution of tartrate of iron and potassium in sherry or Rhenish wine, in the proportion of 10 grains to the fluidounce. The *dose* of the official wine is from 1 to 4 fluidrachms (*Gm.* 4–16), and of the magistral solution nearly twice as much.

VINUM FERRI AMARUM, *U. S.*—BITTER WINE OF IRON.

Vinum de cinchona martiatum, F. Cod.; *Vinum chinæ ferratum.*—*Vin (Ænolé) de quinquina ferrugineux, Fr.*; *Chinæisenwein, G.*

Preparation.—Solution of Citrate of Iron and Quinine 8 parts (2 oz. av. or 1½ fluidounces); Tincture of Sweet Orange-Peel 12 parts (3 oz. av. or 3½ fluidounces); Syrup 36 parts (9 oz. av. or 6½ fluidounces); Stronger White Wine 44 parts (11 oz. av. or about 11 fluidounces); to make 100 parts (25 oz. av. or about 22½ fluidounces). Mix, and filter through paper.—*U. S.*

This is an adaptation of the formula adopted by the American Pharmaceutical Association in 1875, and resembles that of the old French Codex, but contains more iron. The new French Codex directs 2 Gm. each of ferrous sulphate and citric acid to be dissolved in 10 Gm. of boiling water, and this solution added to 990 Gm. of wine of pale cinchona.

Medical Uses.—This solution contains in each fluidrachm nearly 1 grain of the citrate of iron and quinine. It is a mild preparation, but is very efficient in cases of moderate *anæmia* and *debility*. The ordinary *dose* is 1 or 2 fluidrachms (*Gm.* 4–8).

VINUM FERRI CITRATIS, *U. S., Br.*—WINE OF CITRATE OF IRON.

Vinum chalybeatum, F. Cod.—*Vin chalybé, Vin (Ænolé) ferrugineux, Fr.*; *Eisenwein, G.*

Preparation.—Citrate of Iron and Ammonium 4 parts (1 oz. av.); Tincture of Sweet Orange-Peel 12 parts (3 oz. av. or 3½ fluidounces); Syrup 12 parts (3 oz. av. or 2½ fluidounces); Stronger White Wine 72 parts (18 oz. av. or about 18 fluidounces); to make 100 parts (25 oz. av. or about 24 fluidounces). Mix, and filter through paper.—*U. S.*

Dissolve citrate of iron and ammonia 160 grains in orange wine 1 pint (Imperial), and after 3 days filter.—*Br.*

Citrate of iron and ammonia 5 Gm., strong wine (vin de Grenache) 1000 Gm.—*F. Cod.*

Medical Uses.—The wine of citrate of iron has nearly the same qualities as wine

of iron, and, like it, may be used when the stomach is irritable. The *dose* is from 1 to 4 fluidrachms (Gm. 4-16).

VINUM IPECACUANHÆ, U. S., Br., P. G.—WINE OF IPECAC.

Vin d'ipécacuanha, Fr.; *Brechwurzelwein*, G.

Preparation.—Fluid Extract of Ipecac 7 parts (700 grains = 1½ oz. av.); Stronger White Wine 93 parts (9300 grains = 21¼ oz. av.); to make 100 parts (10,000 grains = 22½ oz. av. or about 22½ fluidounces). Mix, and filter through paper.—U. S.

Macerate for a day ipecacuanha 1 oz. in acetic acid 1 fl. oz.; obtain with water 20 oz. of percolate; evaporate to dryness over a water-bath; powder; macerate in sherry wine 1 pint (Imp.) for two days, and filter.—Br. Ipecac 1 part, sherry wine 10 parts.—P. G.

Medical Uses.—Wine of ipecacuanha contains all the virtues of the drug. It is a very inappropriate form for the production of emesis, since the large proportion of alcohol contained in it counteracts the emetic operation of the ipecacuanha, and may be unsuited to the febrile elements of the affections for which it is prescribed. This objection applies less forcibly to its use as a diaphoretic and expectorant. It is especially useful, when associated with spirit of nitrous ether, in favoring diaphoresis in *catharrhal fever*, *muscular rheumatism*, etc. In infantile and also in senile *bronchitis* it is very serviceable when the bronchial secretions obstruct the air-passages, and when an emetic as well as a stimulant operation is called for. In the *vomiting* of pregnancy this preparation, in hourly doses of 1 drop, sometimes arrests that distressing symptom. It is probable that in doses nearly as small it would be found as useful as powdered ipecacuanha has proved in relieving atonic *dyspepsia* and *chronic diarrhœa* from intestinal debility.

The *dose* of wine of ipecacuanha as an emetic is stated to be a fluidounce (Gm. 32) for an adult, and a fluidrachm (Gm. 4) for an infant, but, for the reasons assigned, it is not eligible for this purpose. As an expectorant or diaphoretic the proper dose is from 5 to 10 drops (Gm. 0.30-0.60), repeated every half hour or hour.

VINUM OPII, U. S., Br.—WINE OF OPIUM.

Vinum opii compositum, F. Cod.; *Tinctura opii crocata*, P. G.; *Laudanum liquidum Sydenhami*.—*Sydenham's laudanum*, E.; *Laudanum de Sydenham*, *Vin d'opium composé*, Fr.; *Safranhaltige Opiumtinktur*, G.

Preparation.—Powdered Opium 10 parts (1 oz. av.); Cinnamon, in No. 60 powder, 1 part (44 grains); Cloves, in No. 30 powder, 1 part (44 grains); Stronger White Wine a sufficient quantity; to make 100 parts (10 oz. av.). To the mixed powders add 90 parts (9 oz. av.) of stronger white wine, and macerate the mixture for 7 days, with occasional agitation; then transfer it to a cylindrical percolator, and gradually pour enough stronger white wine upon it to make the filtered liquid weigh 100 parts (10 oz. av. or about 9½ fluidounces).—U. S.

Extract of opium 1 oz. av.; cinnamon-bark, bruised, cloves, bruised, each 75 grains; sherry 1 pint (Imperial).—Br.

Both pharmacopœias have discarded the use of saffron, which is still retained by the French and German Pharmacopœias. Otherwise, the preparation is now practically identical as ordered by the four pharmacopœias. The wine has been replaced in the P. G. by a diluted alcohol. The other formulas are: Opium 200, saffron 100, Ceylon cinnamon 15, Cloves 15, wine 1600 Gm.—F. Cod. Opium 30, saffron 10, Chinese cinnamon 2, cloves 2, alcohol (sp. gr. .894) 150, and water 150 parts.—P. G. That of the French Codex, being made with a sweet wine, is denser (sp. gr. 1.05 to 1.07) than the other preparations. On keeping, this wine deposits some extractive matter and occasionally some narcotine.

The opium strength has been somewhat reduced, 1 grain of powdered opium being now represented by 10.5 minims U. S., and formerly by 8 minims U. S. 1870.

LAUDANUM DE ROUSSEAU, F. Cod., contains about one-fourth its weight of opium, and is therefore considerably stronger than the preceding; it is made by fermenting a mixture of opium 200 Gm., honey 600 Gm., water 3 liters, and beer-yeast 40 Gm.; the filtered liquor is then evaporated to 600 Gm. and mixed with alcohol (sp. gr. .913) 200 Gm.

Medical Uses.—This preparation, also known as "Sydenham's laudanum," is much superior to the tinctures of opium as an internal medicine, on account of its being less apt to nauseate and less offensive in taste and smell. 8 minims, or from 16 to 17 drops (Gm. 0.60-1), may be given as a full *dose*. It is sometimes used as an application to the *conjunctiva* in granular and other chronic forms of inflammation of that membrane.

VINUM QUININÆ, *Br.*—WINE OF QUININE.

Vin de quinine, Fr.; *Chininwein*, G.

Preparation.—Take of Sulphate of Quinia 20 grains; Citric Acid 30 grains; Orange Wine 1 pint (Imperial). Dissolve first the citric acid, and then the sulphate of quinia in the wine; allow the solution to remain for 3 days in a closed vessel, shaking it occasionally; and afterward filter.—*Br.*

Allied Preparation.—VINUM DE CINCHONA, *F. Cod.*: Vinum chinæ, *P. G.* Tincture of cinchona 100, glycerin 100, sherry wine 300 parts.—*P. G.* Cinchona 5, alcohol (sp. gr. .913) 10, red wine 100 parts.—*F. Cod.* The latter formula is alike for pale, red, and yellow cinchona, and in each case the cinchona wine may also be prepared with a strong wine (*vin de liqueur*), such as Grenache, Lunel, Malaga, Madeira, and others, in which case no alcohol is added.

Medical Uses.—It is difficult to perceive the advantages of this preparation over an extemporaneous solution of the citrate of quinia in wine. The *dose* is from 4 to 8 fluidrachms (Gm. 16–32).

VINUM RHEI, *U. S., Br.*—WINE OF RHUBARB.

Tinctura rhei vinosa, *Tinctura rhei Dorelii*, *P. G.*—*Vin de rhubarbe*, Fr.; *Weinige Rhubarbertinktur*, G.

Preparation.—Rhubarb, in No. 30 powder, 10 parts (1 oz. av.); Calamus, in No. 30 powder, 1 part (44 grains); Stronger White Wine a sufficient quantity; to make 100 parts (10 oz. av.). Moisten the mixed powders with 5 parts ($\frac{1}{2}$ oz.) of stronger white wine, pack the mixture in a conical glass percolator, and gradually pour enough stronger white wine upon it to make the filtered liquid weigh 100 parts (10 oz. av. or about 9½ fluidounces).—*U. S.*

The proportions directed by other pharmacopœias are: Rhubarb-root, in coarse powder, 1½ oz. av.; canella alba bark 60 grains; sherry sufficient for 1 pint (Imperial).—*Br.* Rhubarb 6 parts; Grenache wine 100 parts.—*F. Cod.* Rhubarb, finely cut, 8 parts; bitter orange-peel 2 parts; cardamom 1 part; sherry wine 100 parts; in 7 parts of the tincture dissolve 1 part of sugar.—*P. G.*

Medical Uses.—Wine of rhubarb has the same general virtues as the tincture of rhubarb, but is preferable, as being less stimulant. It may be described as cordial, carminative, and *laxative*, and may be used by persons of a *constipated* habit and gouty constitution, and especially by females who add to these conditions scanty and painful menstruation and leucorrhœa. The *dose* is from 1 to 4 fluidrachms (Gm. 4–16).

VINUM RUBRUM, *U. S.*—RED WINE.

Vin rouge, Fr.; *Rothwein*, G.

The juice of the colored fruit of different species of *Vitis*, fermented in the presence of the pericarp.

Origin and Description.—The fruit of most cultivated varieties of the American grapevines and of numerous varieties of the European species have either an amber color or are purple, dark-blue, or nearly black. The juice of these grapes is colorless or nearly so, and if fermented alone yields a white wine, but if fermented with the pericarp or skins the coloring matter of the latter is extracted, and the wine has a red color, varying in shade with the variety of grapes, with the quantity of skins, the length of time they have been in contact with the fermenting liquid, and with the amount of alcohol and acid present. Although many white wines contain tannin, taken up from the pericarp of the fruit or from the seeds, the quantity is usually minute as compared with that present in red wines, and which comes from the same sources. It is obvious, therefore, that red wine agrees in properties and composition with white wine, except so far as these are modified by the red coloring matter and the tannin, the most striking differences being the deep-red color, the distinctly astringent taste, and the effect produced by alkalis, ferric chloride, lead acetate, and other reagents, either changing the color of, or producing precipitates with, tannin and the coloring principle.

VINUM PORTENSE, *U. S.* 1870.—Port wine, *E.*; Vin d'Oporto, *Fr.*; Portwein, *G.*—This is the product of the grape cultivated in the district near the river Douro in Portugal, and is chiefly exported from Oporto. When recently made it is of a red color, which by age changes to a deep reddish-brown, while at the same time a considerable portion of altered astringent matter is deposited and the wine acquires its full flavor.

Port wine is considered to be best when about eight or ten years old. As exported from Portugal, it is always mixed with a certain quantity of spirit, which is added for the purpose of better preservation; its alcoholic strength is thereby increased to from 18 to 22 per cent. Ripeness and strength are said to be imparted to new wine by adding brandy toward the end of fermentation, and the product, particularly the cheaper varieties of port wine, is often artificially colored with preparations containing the juice of elderberries. Port wine has a pleasant vinous odor and an agreeable, warm, sweetish, and slightly astringent taste. In the place of true port wine a variety of French wine, known in commerce as *Burgundy port wine*, is much used in the United States; it resembles port wine in appearance and flavor, and contains about 14 or 16 per cent. of alcohol. California port wine is very similar, and is the product of grapevines originally obtained from the port-wine district of Portugal, and chiefly cultivated in Los Angeles county. Similar wines are also made in other parts of the United States.

CLARET is the English name of dry red wines containing a moderate amount of alcohol, and was originally used for French red wines (*vin claret*, clarified wine), but is now applied to many wines of American growth from California, as well as from the Mississippi Valley and eastward to the Atlantic coast. Some of the most esteemed red wines of France are produced in Gironde and exported from Bordeaux, and the red wines produced in other sections of France have, like the former, been known in Europe as *Bordeaux wines*. Much of the wine exported is more or less artificial. (See VINUM ALBUM, process of Petiot and Gall for wine-improving.)

Constituents.—In addition to the constituents mentioned elsewhere (see VINUM ALBUM), red wine contains tannin, partly derived from the casks, but mainly from the seeds and integuments of the grape, and giving with ferric salts green-brown or green-black precipitates. The red coloring matter, *anolin* or *anolic acid*, is a red-brown or purplish-red powder, which is nearly insoluble in water, in carbon bisulphide, and in chloroform, but soluble in dilute acids and in alcohol; it is not unlikely that the coloring principles of different grapes vary, and are more or less modified by the constituents and treatment of wine.

The following summary of analyses of American red wines by Prof. H. B. Parsons shows the variation in composition:

	64 Dry Wines.			12 Port Wines.		
	Average.	Highest.	Lowest.	Average.	Highest.	Lowest.

Tests.—The pharmacopœial requirements as to the quality of red wines are practically identical with those for white wine. (See VINUM ALBUM.) The nature of the coloring matter and its freedom from aniline colors is characterized as follows: “If 50 Cem. of red wine be treated with a slight excess of water of ammonia, the liquid should acquire a green or brownish-green color; if it be then well shaken with 25 Cem. of ether, the greater portion of the ethereal layer removed and evaporated in a porcelain capsule with excess of acetic acid and a few fibres of uncolored silk, the latter should not acquire a crimson or violet color (absence of aniline colors). With test solution of acetate of lead red wine should form a heavy precipitate, which may vary in color from bluish-green to green.”—*U. S.*

On the gradual addition of ammonia the red color of wine is changed to purple, blue-green, and is destroyed, with the production of a brown tint. Many other organic coloring matters have a similar behavior, while others are changed to purple (cochineal, log-wood); fuchsin is slowly discolored, with the formation of rosaniline, which is soluble in ether, and on the addition of acetic acid again produces a red color. The precipitate produced by lead subacetate is dingy gray, with a blue or green tint; the age of the wine and the presence of tannin and other constituents influence the shade of the color. Other organic coloring matters are precipitated by the same reagent red (Brazil-wood), green

(elderberries), or blue (logwood). Similar shades of color are produced upon white filtering-paper which has been steeped in a solution of lead acetate. Fuchsin is not precipitated, but may be extracted by agitating the liquid with ether. According to André (1880), the coloring matter of huckleberries is identical with that of wine, and in order to detect the addition of the juice of these berries it is necessary to show the presence of citric acid. (See VINUM ALBUM.)

Pastrovich (1882) again recommends black oxide of manganese, which was originally suggested by Facen (1870), and states that, after repeated agitation with the oxide, after 15 minutes genuine red wine, also wine colored with huckleberries, elderberries, or cochineal, become nearly colorless, while the color of Brazil-wood, logwood, and orchil changes to brownish-yellow, and that of fuchsin remains unaltered. Wine containing only .002 Gm. of fuchsin to the liter, treated in this manner, yields a rose-colored filtrate.

Medical Action and Uses.—The essential difference between red and white wines consists in the presence of tannic acid in the former, which is derived from the crushing of the stems of purple grapes in the process of manufacturing wine. This ingredient is most abundant in port and heavy Bordeaux wines, and hence they and the other wines that resemble them, including several American varieties, differ from white wines in the relative slowness of their absorption from the stomach, and consequently in their less prompt production of intoxication. Moreover, from the same cause they act less injuriously upon the coats of the stomach. Red wines, in general, have relatively more of the tonic and less of the excitant properties possessed by white wines, and are especially to be preferred to the latter when a sustained instead of a transient stimulation is desired, and when, in addition to this, an astringent action is intended. Hence the red wines are eminently the wines of convalescence, and are of general use in all cases of excessive discharges of blood, pus, etc. in which they are not contraindicated by other reasons. Unfortunately, red wines are more generally adulterated or factitious than white wines, with the exception of sherry. In an English manual for wine-dealers it is said: "To keep wine from turning sour put in the casks 2 pounds 3 ounces of small shot." And, as if this were not villainous enough, it proceeds: "In extreme cases, when all the previous recipes have been tried without any satisfactory result, take a pinch of oxalic acid and put it into the bottle" (*Brit. and For. Med.-Chir. Rev.*, Apr. 1858, p. 324). Red wines are often manufactured out of alcoholic dilutions colored by logwood, rhatany, beets, litmus, etc. Astringency is given them by means of alum, oak- or willow-bark, etc., as elsewhere more particularly described.

The more astringent red wines are used for injecting *hydroceles*, the *vagina*, *urethra*, etc. affected with chronic profluvia, *fistulous sinuses*, etc. But the various astringent tinctures would answer equally well.

VIOLA TRICOLOR, U. S.—VIOLA TRICOLOR.

Herba violæ tricoloris, s. *Herba jaceæ*, P. G.—Pansy, Heart's ease, E.; *Pensée sauvage*, Fr.; *Stiefmütterchen*, *Freisamkraut*, *Dreifaltigkeitskraut*, G.

The wild-grown flowering herb of *Viola tricolor*, Linné.

Nat. Ord.—Violaceæ.

Origin.—The violets are mostly perennial, or rarely annual or biennial, herbs, with alternate stipulate leaves, and with axillary flowers having five persistent auriculate sepals, five somewhat unequal petals, of which the lower one is saccate or spurred, five strongly connivent stamens, of which the two lower ones bear a spurred nectary upon the back, and one superior pistil with three placentas, ripening into a three-valved, many-seeded capsule; the globular or ovate seeds have a small caruncle and hard testa, and contain a straight embryo imbedded in fleshy albumen. The officinal species is an annual or biennial indigenous to Europe and Northern Asia, naturalized in the United States, and frequently cultivated in many varieties as an ornamental plant. Only the wild-grown plant is to be collected.

Description.—Pansy has a thin, spindle-shaped root and an erect or ascending angular and branching, nearly smooth stem, 4 to 8 inches (10–20 Cm.) high. The leaves vary between roundish-cordate and oval, crenate and nearly entire, are about an inch (25 Mm.) long, petiolate, and have prominent, leaf-like, lyrate-pinnatifid stipules. The flowers are on long peduncles, and have the corolla partly yellowish, blue, and purple, or occasionally variegated and longer than the calyx (variety *vulgaris*, *Koch*), or the corolla scarcely exceeds the calyx, and is yellowish or occasionally partly purplish (var. *arvensis*, *Murray*). The last form is the only one recognized by the French Codex; it is frequent

in sandy fields of North America, and apparently indigenous. The dry herb is inodorous and has a bitterish, mucilaginous, and slightly acrid taste, the acidity residing mainly in the root.

Constituents.—Boullay (1824) found in the herb a yellow coloring matter and much mucilage, but no violine; Cuseran (1847), in addition to these, sugar, bitter principle, resin, and potassium nitrate. Mandelin (1879) detected free *salicylic acid* in this plant, and subsequently (1881) determined it to amount to .1068 per cent. in the wild-grown, air-dry plant of the variety *arvensis*, while other varieties contained less, and the cultivated plant only .043 per cent. The acid is obtained by agitating the aqueous solution of the alcoholic extract with ether; the petals contain a minute quantity, the seeds a mere trace, of the acid. A salt of salicylic acid could not be found. Mandelin examined also the yellow coloring matter, which is the glucoside *violaquercitrin*, yielding with dilute acids 3 molecules of sugar and 1 of quercetin, besides a fluorescing compound.

Allied Species.—*VIOLA PEDATA*, *Linné*, Bird's foot violet. The leaves and rhizome were formerly officinal. It grows in sandy soil from the New England States southward, and westward to the Mississippi. It has a short, erect, and truncate rhizome, about an inch (25 Mm.) long and nearly as thick, and beset with slender rootlets. The leaves are radical, smooth, pedately five- or seven-parted, and have the divisions linear or narrowly spatulate, and occasionally slightly toothed at the apex. The flowers are large, about an inch (25 Mm.) broad, beardless, vary in color between light-blue and dark-purple, and have a very faint violet color, which is observable only with a large number of flowers. The leaves and flowers have a mucilaginous and sweet taste; the taste of the rhizome is mucilaginous, bitter, and somewhat acrid. The plant flowers in May, and frequently a second time in August and September.

VIOLA CUCULLATA, *Aiton*, is the common blue violet of North America, growing in meadows and in dry grassy places and open woods. The rhizome is spreading, forms compact masses, and is covered with numerous short fleshy branches. The leaves are very variable, heart-shaped at the base, with the basal lobes rolled up. The flowers are somewhat bearded, light- or dark-blue, violet-colored, or variegated. The variety *V. palmata* has the later leaves palmately lobed.

VIOLA ODORATA, *Linné* (Bentley and Trimen, *Med. Plants*, 25).—Sweet-scented violet, *E.*; *Violette odorante*, *Fr.*; *Märzveilchen*, *G.*—It is indigenous to Europe and Northern Asia, is frequently cultivated, and grows to a certain extent spontaneously in various parts of North America. It has an oblique rhizome and produces long, filiform runners. The leaves are reniform or heart-shaped, obtuse, and crenate. The flowers are dark-blue or sometimes whitish, bearded, and have a very agreeable odor. For pharmaceutical purposes the dark-blue flowers alone are collected, deprived of the calyx, and only the corolla is used in the fresh state for preparing

SYRUPUS VIOLEÆ ODORATÆ, *F. Cod.* Fresh violet-petals 10 parts, boiling water 20 parts; in 21 parts of the infusion dissolve 38 parts of sugar.

The rhizomes of the perennial, and more particularly the acaulescent, violets appear to contain *violine*, which Boullay (1828) obtained from all parts of the sweet-scented violet, but in largest quantity from the rhizome. It is prepared by removing from the alcoholic extract chlorophyll and fat by means of ether, boiling the residue with diluted sulphuric acid, adding to the filtrate oxide of lead, evaporating, and exhausting the residue with strong alcohol. *Violine* is a yellowish, bitter, and fusible powder, which is more readily soluble in water than emetine, but less so in alcohol; is insoluble in ether, and appears to combine with acids to not well-defined saline compounds. It merits further investigation. The blue coloring matter of violets turns green, and afterward yellow, with alkalis.

ANCHIETEA SALUTARIS, *Saint-Hilaire*, s. *Noisetia pyrifolia*, *Martius*. The root of this shrub, which is indigenous to Brazil, is used as a cathartic and emetic. It is about the thickness of a finger, is brownish-red, and has a yellowish, nauseous, and bitter bark, covering the hard brownish wood. Peckolt (1859) found in the root starch, sugar, gum, tannin, a little resin, and about $\frac{2}{5}$ per cent. of *anchietine*, which forms crystallizable salts, crystallizes in straw-colored needles, is insoluble in ether, sparingly soluble in water, and freely soluble in alcohol, and acquires with sulphuric acid a violet color, turning black.

Medical Uses.—Very little is known of the medicinal virtues of the formerly officinal violet, *V. pedata*, which, as far as can be judged, does not differ much in its qualities from the European species, which have long been used in medicine. Sweet violets (*V. odorata*) were anciently held to be refrigerant and astringent in "ardor of the stomach," inflammation of the eyes, and prolapse of the anus and of the uterus, and also to restrain suppuration. By the Arabians they were employed in coughs and affections of the kidneys and of the liver, and, when prepared with sugar, as a laxative. The syrup of violets, which to this day is used in France, was directed by the Arabians in pulmonary affections. It was also formerly recommended as a local remedy for *aphthæ*; internally, an infusion of the flowers was given in infantile *convulsions*; and the powder, as well as

an infusion of the root, has been used in the same manner as ipecacuanha in the treatment of infantile dysentery.

An alkaloid procured from this species is represented to have exhibited the properties of emetine, causing vomiting, purging, and great prostration in dogs, and in man analogous effects in some cases, but not uniformly. The powdered root applied to the denuded skin has sometimes acted as an emeto-cathartic. Similar effects have been obtained from *V. canina*.

V. tricolor (heart'sease) also produces disturbance of the stomach and bowels, and sometimes diuresis. Its continued use is said to occasion sweating and a pustular eruption of the skin, and to impart to the urine a smell like cat's urine or that of conium. It once had a great popular repute in Europe as a purifier of the blood and as a remedy in chronic bronchial and intestinal catarrh, in cutaneous eruptions, and particularly in *crusta lactea* (eczema infantile). In these affections it was administered in a decoction of milk and applied in fomentations. Cazin (*Traité des Plantes médicinales indigènes de France*, 2ème éd., p. 734) sets forth at length the virtues ascribed to it in the cure of scrofulous and other cutaneous diseases by Bergius, Matthiolus, Bauhin, Boeckler, Strack, Murray, Hufeland, and many others, including the imaginative Hahnemann, and also the denial of their existence by other physicians. A similar history had long before been given by Richter (*Ausführliche Arzneim.*, ii. 235), who concludes it by observing, "After all, viola has no special virtues in these affections; at the best, it can only afford some support to other and more efficient remedies." It had also some repute in constitutional syphilis. In Europe the syrup of violets is sometimes employed as a laxative for infants, but its chief use is to give a fine color to mixtures.

VISCUM.—MISTLETOE.

Gui de chêne, Gillon, Fr.; *Mistel*, G.

Viscum album, Linné, and *Viscum* (Phoradendron, Nuttall) *flavescens*, Pursh.
Nat. Ord.—Loranthaceæ.

Origin and Description.—The mistletoes are small parasitic evergreen shrubs, growing mostly upon deciduous-leaved trees, and penetrating with their simple roots through the bark into the wood. *Viscum album* is indigenous to Europe, and is chiefly found upon apple, pear, plum, and similar trees, but grows also upon poplars, birches, beeches, and others. *Viscum flavescens* is an American species, growing upon oaks, elms, apples, etc. in the Southern United States and northward to New Jersey, and westward in the Mississippi Valley. Both plants are of a yellowish-green color, $\frac{1}{2}$ to 2 feet (15–60 Cm.) high, much branched, jointed, and have opposite, often scale-like leaves and monœcious or dioecious flowers in small clusters or short spikes. The leaves of the European species are lanceolate or spatulate, obtuse and entire; those of the American plant are obovate or oval. The fruit of both species is a small, whitish, one-seeded berry. The branches are usually collected. They have an unpleasant heavy and rather weak odor and a mucilaginous, sweetish, bitter, and somewhat astringent taste.

LORANTHUS EUROPÆUS. Linné, is the *viscum quernum* of ancient writers. It is a somewhat larger and thicker shrub, which grows upon oaks and chestnuts in Eastern and Southern Europe, and has a grayish or dark-brown bark and pale-yellow berries.

Constituents.—Mistletoe has been analyzed by Gaspard, Funcke, Winckler, Macaire, and Reinseh. It contains mucilage, sugar, an odorous principle, fixed oil, resin, traces of tannin, and various salts. The most interesting constituent is *viscin*, also called *bird-lime*, or more properly *bird-glue*, from the German name *Vogelleim*. It is insoluble in water, alcohol, and fixed oils, but dissolves in ether and oil of turpentine, and on evaporating the solvents remains behind as a yellowish viscous and tenacious mass. It seems to be present in the mistletoe in small proportion, but a larger quantity is formed by a kind of fermentation. The same or a similar compound may be obtained from the inner bark of the European holly, *Ilex aquifolium*, Linné, from the root of *Gentiana lutea*, Linné, and from other plants. It is employed for catching small birds; hence the name *Vogelleim*.

Medical Action and Uses.—The operation of mistletoe is as uncertain as its virtues are doubtful. The berries are reported by some writers (Cazin) to be innocuous, but others state that they are emetic and purgative, and instances are given in which very young children have suffered convulsions, and even death, from eating large quantities of them. It seems not impossible that these effects may have been due to indigestion alone. It is true that a case is recorded in which after several children had eaten the berries of *V. flavescens* they were affected with vomiting, great thirst, tenesmus, and bloody and

mucous stools. In one case death ensued in a state of collapse. In Europe, however, the dried young twigs and leaves of mistletoe have long been used in medicine for various nervous affections, including *chorea*, *asthma*, and *spasmodic colic*, but chiefly for *epilepsy*, although sometimes for *hysteria* (Richter, *Ausf. Arzneim.*, ii. 822). Long (*New Preparations*, 1878) "used mistletoe in the forms of infusion, tincture, decoction, and fluid extract in many cases of *menorrhagia* and *post-partum hemorrhage* with gratifying results." He conceived that it incited the natural rather than the tonic contraction of the uterus. A physician in South Carolina refers to three cases of abortion in negroes produced by this growth (*Med. Record*, xvii. 276). In 1881 it was alleged to act upon the heart like *digitalis* (Park, *Practitioner*, xxvii. 346). It was formerly given in powder in the dose of from 10 to 60 grains (Gm. 0.60-4), or in a decoction made from $\frac{1}{2}$ ounce to 2 ounces of the plant in 8 ounces of water (Gm. 16-64 in Gm. 250), and in tablespoonful doses several times a day.

VITELLUS, U. S.—YELK OF EGG.

Ovi vitellus, Br.; *Yelk of egg*, E.; *Jaune d'œuf*, Fr.; *Eidotter*, *Eigelb*, G.

The yelk of the egg of *Gallus Bankiva*, var. *domesticus*, *Temminck*, s. *Phasianus* (*Gallus*, *Linne*).

Class Aves; *order Gallinæ*.

Origin.—The domestic fowl originated from the *red jungle-fowl*, *G. Bankiva*, which inhabits Java and the adjacent islands, Northern India, Cochin China, and the Philippines. At the present time numerous varieties of it are found in all civilized countries. The eggs (*Ovum*, U. S. 1870. *Ovum gallinaceum*—*Egg*, E.; *Œuf*, Fr.; *Ei*, G.), which are the part employed for pharmaceutical and medical purposes, consist of the shell and lining membrane 10.7 parts, albumen 60.4 parts, and yelk 28.9 parts (Prout, 1822).

Description and Composition.—1. *TESTA OVI*.—*Egg-shell*, E.; *Coquille*, Fr.; *Eierschale*, G.—It consists, according to Prout, of 97 parts calcium carbonate, 1 part calcium and magnesium phosphates, and 2 parts organic matter. Vauquelin's results were 89.6, 5.7, and 4.7 respectively.

2. *ALBUMEN OVI*, Br.—*White of egg*, E.; *Blanc d'œuf*, Fr.; *Eiweiss*, G.—It consists of two or three laminae, the total average weight being 23.01 Gm. (Lehmann), or 24.8 Gm. (Poleck), and contains 82 to 88 per cent. of water, and on the average 13.32 of solid constituents, including 0.65 of ash, as well as minute traces of fat, sugar, and extractive. The ash of the egg albumen consists of 42 per cent. chloride of potassium, 9 of chloride of sodium, 12 of carbonic acid, the remainder being phosphates and sulphates of the alkalis, silica, iron, lime, and magnesia. The organic portion of the white, the *albumen* proper, is a protein compound; the average elementary composition is 53.7 C, 15.5 N, 7.1 H, 22.1 O, and 1.6 S. Its aqueous solution rotates the plane of polarized light to the left, and may be evaporated in thin layers below 50° C. (122° F.) without change, but on being heated to near 75° C. (176° F.) it is coagulated and becomes insoluble in water. Albumen is precipitated from its solutions by most mineral and by some organic acids, but not by phosphoric or acetic acid. It is soluble in caustic alkalis, and precipitates the salts of most heavy metals, hence its value in cases of poisoning by salts of mercury, copper, etc. Albumen is also precipitated by volatile oils, camphor, phenol, and by tannin, the last precipitate being soluble in an aqueous solution of tannin. Alcohol coagulates albumen, and ether precipitates it, the precipitate being only partially soluble in water. Farsky (1878) succeeded in obtaining what appears to be a definite compound of salicylic acid with albumen, by stirring the two together for some time, washing with ether and hot water, and drying in an air-bath at about 120° C. (248° F.); it was found to contain 14.16 per cent. of salicylic acid and 85.84 of albumen, and to be as easily digestible as the uncombined albumen. When boiled with *Millon's reagent* the precipitate as well as the liquid turns red, and albumen cautiously heated with strong hydrochloric acid is colored violet-blue. Other protein compounds show a like behavior.

3. *VITELLUS OVI*.—The yelk is a viscid yellow or reddish-yellow opaque liquid, which is without odor, has a bland taste, an alkaline reaction, and must be regarded as a dense emulsion consisting of oil suspended in water by means of albumen. When triturated with water a whitish emulsion is obtained; the addition of alcohol causes it to coagulate, and when agitated with ether it separates a white mass and yields to ether an orange-yellow fat. Yelk is coagulated by heat. It contains 48 to 55 per cent. of water, 16 to 18 per cent. of *vitellin* (which is probably a proteid closely related to casein, and mixed with about one-fourth of albumen), 29 to 31 per cent. of fat (21.3 parts of which are

olein and margarin, according to (Gubley), 1.5 per cent. inorganic salts, coloring matter, a small portion of sugar, and 0.42 of cholesterin. Gubley has separated from the ethereal extract of yolk a substance which he named *lecithin*, and which on boiling with baryta yields *neurine* and stearic and *phosphoglyceric acids*. The fat obtained by expressing the coagulated yolk, or by exhausting it with ether, is occasionally used under the designation of *oleum ovi* (Oil of eggs, *E.*; Huile d'œufs, *Fr.*; Eieröl, *G.*).

Preservation.—Eggs may be preserved for a considerable length of time by covering the shell with a substance impervious to water, thus closing the pores so as to exclude the air. This may be done by wax, fat, paraffin, gum, or by similar substances. Packing them with the small end downward in dry salt, milk of lime, etc. has likewise been recommended.

Pharmaceutical Uses.—The white of egg is used for the clarification of syrups, honey, and other liquids. The yolk is employed for emulsionizing fixed and volatile oils and camphors.

Off. Prep.—Glyceritum amyli, Mistura chloroformi, *U. S.*; Mist. spir. vini gallici, *Br.*

The dietetic value of yolk of egg cannot be considered in this work. Its value in pharmacy has been described.

Medical Action and Uses.—*Egg-shells* were long used for the various purposes to which chalk is now applied internally. Like crabs' eyes and claws, corals, and oyster-shells, which were formerly employed, they contain a certain proportion of animal matter which mitigates the action of the calcareous constituent. They were an ingredient of a secret remedy for *gravel*, for a knowledge of which the British Parliament paid an extravagant sum of money. The *white of egg* forms with solutions of corrosive sublimate and of sulphate of copper compounds which are nearly insoluble, and hence it has been used in *poisoning* with these salts, first to neutralize and then to evacuate them. Its demulcent and protective action is also advantageous. It is applied to the treatment of *burns* and *erysipelas*, either alone or emulsified with oil, or coagulated by alum in the form of alum curd. The latter is an excellent application in acute *conjunctivitis*. Diluted with water, sweetened, and flavored, fresh egg albumen forms an agreeable and useful drink in numerous cases of *gastro-intestinal* inflammation and irritation. Albumen is sometimes used as a substitute for starch in the application of fixed *bandages*. The *yolk of egg* is more nutritious and digestible than the white, and is habitually employed whenever it is desired to give the largest amount of nutriment in a small bulk and in the most digestible form. The yolk of a hard-boiled fresh egg readily crumbles, and is therefore easily acted upon by the gastric juice. The fresh yolk, beaten with sugar and mixed with hot water, and with the addition of a little brandy and nutmeg or cloves, forms a customary draught at the commencement of catarrhal and rheumatic (muscular) affections. It is used also to make emulsions for the administration of castor oil, cod-liver oil, oil of turpentine, etc., either by the mouth or the rectum. Externally, it is sometimes, and very usefully, employed as a dressing for *burns*, *scalds*, *abrasions*, etc., and to soften the crusts of *cutaneous eruptions*, *cerumen* in the auditory canal, etc.

WINTERA.—WINTER'S BARK.

Cortex winteranus.—Écorce de Winter, Cannelle de Magellan, *Fr.*; Winter's Zimmt, *G.*

The bark of *Drimys Winteri*, *Forster*, s. *Wintera aromatica*, *Murray*.

Nat. Ord.—Magnoliaceæ, Winterææ.

Origin.—*Drimys Winteri* is a small tree growing in the western part of South America from the Straits of Magellan northward to Mexico. It has coriaceous, oblong and obtuse or lance-oblong, dark-green, and on the lower side pale bluish-green, entire leaves, axillary clusters of whitish flowers, and about four or eight black obovate berries containing three or four seeds. *D. mexicana*, *Sessé*, s. *chilensis*, *De Candolle*, and *D. grana-tensis*, *Linne filius*, are now regarded as varieties, and the last one is mentioned by the French Codex as the present source of the drug.

Description.—Winter's bark is curved or in quills, between $\frac{1}{8}$ and $\frac{1}{4}$ inch (5–8 Mm.) thick, externally of a gray or whitish color with brown patches, and underneath the corky layer brown. The inner surface is brown, and marked with longitudinal ridges from the prominent bast-fibres. The bark breaks with a short fracture, and has a peculiar odor and a warm and very pungent taste. The transverse section is of a brown-red color, mottled with whitish sclerenchyma, which in the primary bark underneath the thin corky layer forms transversely-elongated groups, and in the bast-layer is seen partly in groups, partly in long radial lines; resin-cells are scattered in the outer and inner tissue.

Substitutions.—The Winter's bark of commerce has usually been an entirely different bark, occasionally that of *Canella alba*, *Linneé*, but more frequently obtained from *Cinnamodendron corticosum*, *Miers* (see page 372).

Constituents.—The principal constituents of Winter's bark, as ascertained by Henry (1820), are 1.2 per cent. of volatile oil, about 10 per cent. of pungent resin, and 9 per cent. of tannin, with extractive matter and a little starch.

Allied Species.—The Australian species, *Drimys axillaris*, *Forster*, and *D. lanceolata* (*Tasmania aromatica*, *R. Brown*) have likewise pungently aromatic barks, and the fruit of the latter is used like pepper.

Medical Action and Uses.—The action and uses of Winter's bark resemble those of cascarilla and canella. It is a warm tonic of the digestive organs, increasing the appetite and improving the digestion, especially when deranged by *flatulence* and *colic*. The *dose* of the powder is about 30 grains (Gm. 2), and a vinous infusion may be prepared by displacement with an ounce of the bark to 12 ounces (Gm. 32 in Gm. 380) of sherry wine.

XANTHORRHIZA.—YELLOW-ROOT.

The rhizome and root of *Xanthorrhiza apiifolia*, *L'Heritier*. Bentley and Trimen. *Med. Plants*, 9.

Nat. Ord.—Ranunculaceæ.

Origin.—This plant is also known as *shrub yellow-root* to distinguish it from *Hydrastis canadensis*. *Xanthorrhiza* is a shrub 1 or 2 feet (30–60 Cm.) high, growing in shady places near streams in New York and from the mountains in Pennsylvania southward to the Gulf of Mexico. The clustered stems are thin, of a grayish color externally, smooth, and annulate from the distant leaf-scars. The leaves are alternate, crowded at the ends of the branches, long-petiolate, pinnate, and have three or five ovate or lanceolate, cleft, and toothed leaflets, with wedge-shaped bases. The flowers are polygamous and in compound drooping racemes, appearing in early spring.

Description.—Yellow-root consists of a much-branched and bent rhizome several feet long. The thicker portions are about $\frac{1}{2}$ inch (12 Mm.) in diameter, the branches thinner, some being only $\frac{1}{16}$ inch (1.5 Mm.) thick, longitudinally wrinkled, of a light yellowish-brown color externally, and rather sparingly beset with brittle rootlets. The bark is thin, internally of a deep-yellow color, and separates readily from the bright-yellow, tough wood, which is radially striate by medullary rays and encloses a thin central pith. The rhizome breaks with a short fibrous fracture, is inodorous, and has a bitter taste, which is more marked in the cortical portion. Portions of the stems, having a larger brownish pith and yellow wood, are often present.

Constituents.—Perrins (1862) showed that yellow-root contains berberine; he obtained only $7\frac{1}{2}$ grains of the nitrate from 1 pound of the drug. About the same time W. M. Merrill made a similar observation. Whether berberine is associated with a white alkaloid, as is frequently the case, has not been determined. The parenchyma contains starch. The other constituents of the drug are not known.

Medical Uses.—Yellow-root has long been known as an indigenous *tonic* medicine, and compared either to quassia or columbo. It may be given in decoction, tincture, or powder. Of the last the *dose* is said to be 40 grains (Gm 2.60).

XANTHOXYLUM, U. S.—PRICKLY ASH.

Toothache tree, *Angelica tree*, *Suterberry*, E.; *Clavallier*, *Frêne épineux*, Fr.; *Zahnwech-rinde*, *Zahnwechholz*, G.

The bark of *Xanthoxylum fraxineum*, *Willdenow* (s. *X. americanum*, *Miller*), and of *Xanthoxylum carolinianum*, *Lambert*.

Nat. Ord.—Rutaceæ, Xanthoxyleæ.

Origin.—Both species of prickly ash are indigenous to North America, and have pinnate leaves and dioecious, tetramerous or pentamerous flowers, the pistillate ones containing from three to five free ovaries, which produce thick and fleshy two-valved and one- or two-seeded capsules.

X. AMERICANUM grows in rocky woodlands and on river-banks from Canada southward to Virginia and North Carolina. It is shrubby, and attains a height of 10 or 12 feet (3–3.6 M.). The leaves have nine or eleven ovate-oblong, nearly sessile, somewhat serrulate, and on the lower surface downy leaflets. The small, greenish flowers are in umbellate, axillary clusters, appear in April before the leaves, and are destitute of a calyx. The capsules are roundish, red, and contain black, shining seeds.

X. CAROLINIANUM is found near the coast from Virginia southward to Florida and westward to Texas. It is a small tree, but sometimes grows to the height of 30 or 40 feet (9–12 M.). Its leaves have from seven to eleven ovate-lanceolate, crenate-serrulate, unequal-sided, and shining leaflets, the terminal one alone being equilateral. The numerous greenish flowers are in terminal cymes, appear in June after the leaves, and contain three pistils.

Description.—NORTHERN PRICKLY-ASH BARK is in small, curved, or quilled fragments, about 2 inches (5 Cm.) or less long, mostly about $\frac{1}{8}$ inch (1 Mm.) thick, and occasionally mixed with pieces nearly $\frac{1}{4}$ inch (3 Mm.) thick. The corky layer is very thin, of a brown-gray color, nearly smooth or faintly furrowed longitudinally, occasionally superficially fissured transversely, and marked with some scattered warts, becoming transversely elongated. Irregular whitish patches are usually observed on the surface of the bark, and numerous minute, black, and shining hemispherical dots, which are the perithecia of a lichen, probably a species of *Verrucaria*. The brown, glossy spines are not numerous, but are about $\frac{1}{4}$ inch (6 Mm.) long, straight, two-edged, and have a narrow linear base about $\frac{1}{8}$ inch (18 Mm.) long. The outer bark underneath the corky layer is of a green color, and the inner bark whitish or yellowish. The inner surface is smooth, or finely striate if obtained from older branches. The bark is quite brittle, breaks with a short, non-fibrous fracture, and exhibits upon transverse section a somewhat tangential arrangement of the tissue. It is inodorous and has a slightly aromatic, bitterish, and strongly pungent taste.

SOUTHERN PRICKLY-ASH BARK resembles the preceding, except that it is about $\frac{1}{12}$ inch (2 Mm.) thick, and bears on its surface many conical, corky projections, which are $\frac{1}{8}$ to $\frac{1}{4}$ inch (1–2 Cm.) high, and have an oblong or roundish base an inch (25 Mm.) or more in length. Sometimes a number of these cones are crowded together. The stout brown spines are situated upon elevated corky bases.

Substitution.—The bark of *Aralia spinosa*, *Linne*, which plant is known by the same common names as the two species of *Xanthoxylum*, is sometimes collected in place of the bark of the latter. *Aralia*-bark is described on p. 255.

Allied Species.—XANTHOXYLUM CLAVA HERCULIS, *Linne*. This is the Hercules' club of the West Indian Islands, is closely allied to the Southern prickly ash, and is considered by some botanists as being identical with it.

X. FLORIDANUM, *Nuttall*, is known as *satin-wood*, and considered to be identical with *X. caribæum*, *Lamarek*.

X. PTEROTA, *Kunth*, grows from Florida and Texas to Brazil. The wood is yellow, dense, and very hard; the bark and leaves are pungent.

X. ALATUM, *Roxburgh*, of Northern India. **X. PIPERITUM**, *De Candolle*, a native of Japan, and several other species, yield pungently aromatic fruits which are employed as condiments in the East. The bark, leaves, and fruit of most species are pungent or acrid.

Constituents.—Prickly-ash bark was examined by Dr. Staples (1829), who obtained from it a little volatile oil, a green-colored fixed oil, resin, and other common vegetable principles, and a crystalline body which he named *xanthoxylin*, but the nature of which was not further characterized. The bitter principle of the bark of *X. clava Herculis* was isolated by Chevallier and Pelletan (1827), and designated as *xanthopierit*, but was found by Perrins (1863) to be identical with *berberine*. G. H. Colton (1880) examined Southern prickly-ash, and obtained an alkaloid which seems to differ from berberine; it is yellowish, bitter, soluble in alcohol and water, insoluble in benzin, ether, and chloroform, and becomes purplish-brown with sulphuric acid, and bright-red, changing to yellow, with nitric acid. Colton obtained also a trace of volatile oil, sugar, resins, a colorless and tasteless crystalline principle, and 12.4 per cent. of ash, of which 20 per cent. was soluble in water, the remainder in hydrochloric acid. Prof. Lloyd (1876) isolated from Northern prickly ash a crystalline substance which is probably identical with the one previously mentioned; it is insoluble in water, soluble in boiling alcohol, is turned yellow by nitric acid, and dissolves with a deep-red color in sulphuric acid.

The fruit of *X. piperitum* was examined by Stenhouse (1854, 1857). On being distilled with water, volatile oil is obtained, which on exposure to cold yields crystals of *xanthoxylin*, $C_{20}H_{24}O_8$. It melts at 80° C. (176° F.), has a slight odor and aromatic taste, and a neutral reaction. The liquid portion of the volatile oil is *xanthoxylene*, $C_{20}H_{16}$, is colorless, has a strong, agreeable odor, boils at 162° C. (324° F.), and yields, with hydrochloric acid a liquid compound.

Medical Action and Uses.—Xanthoxylum appears to be an arterial and nervous stimulant, which displays its virtues in producing diaphoresis, expelling *flatus*, and allaying muscular *rheumatic* pains. Locally it is an acrid irritant, and hence has been

much used as a sialagogue. Its infusion may be applied on compresses or otherwise for producing revulsion. These qualities have caused it to be compared with mezeoreon, and, like it, to be used as a remedy for chronic constitutional *sypphilis*. It has also been employed as an *emmenagogue*, like other acrid stimulants; and doubtless, like them, it will promote the *secretion of milk* when applied to the mammae under appropriate circumstances. A decoction may be prepared by boiling an ounce of it in 3 pints of water until reduced to 2 pints (Gm. 32 in Gm. 1500, reduced to Gm. 1000). About a pint should be taken, in divided doses, within 24 hours. A saturated tincture may be used in the dose of 10 drops (Gm. 0.60).

X. Naranjillo has attracted notice from its being sialagogue, sudorific, and diuretic, like jaborandi.

XYLOL.—XYLOL.

Xylol, *Xylene*, Fr.; *Xylol*, G.

Formula C_8H_{10} . Molecular weight 106.

Origin and Preparation.—Xylol was discovered by Cahours (1850) in crude wood-spirit, and was subsequently found by Völckel (1853) in wood-tar (see *Pix Liquida*), and by Church (1855) in coal-tar. It is obtained from the oily liquid separating from diluted crude wood-spirit and from the light oil of wood-tar or coal-tar, by treating these liquids first with sulphuric acid, and afterward subjecting them to fractional distillation, collecting only that portion which distills between 136° and 141° C. (277° – 286° F.). It may also be prepared artificially from several benzol derivatives.

Properties.—Xylol is a thin, colorless, oily liquid, resembling benzol in odor, has a burning taste, and is insoluble in water, but dissolves readily in alcohol. It is *dimethylbenzol*, $C_6H_4(CH_3)_2$, and there are three modifications of it, two of which boil at 137° C. (278.6° F.), while orthoxylol boils at 141° C. (285.8° F.). The boiling-point of the isomeric ethylbenzol, $C_6H_5.C_2H_5$, is 134° C. (273.2° F.). Xylol unites with sulphuric acid to *sulphoxylic acid*, the barium salt of which crystallizes from hot water in transparent scales (Church). On treating xylol with cold concentrated nitric acid, *nitroxylol* is obtained as an oily liquid having a less agreeable odor than nitrobenzol. By oxidation xylol is converted into *toluic acid*, $C_8H_7O_2$, and *phthalic acid*, $C_8H_6O_4$.

Medical Action and Uses.—The only purpose for which this preparation appears to have been employed in medicine is to moderate the angina and eruption in the throat and to diminish the fetid exhalation from this part and from the skin in *small-pox*. It seems to have been efficient, when applied to the throat in a gargle, spray, or wash, in lessening the swelling and difficulty of swallowing, and destroying the fetor when used upon the skin in a similar manner. It may also be given suspended in mucilage and syrup. The *dose* for an adult is stated to be 10 or 15 drops (Gm. 0.60–1), and for children 3 or 4 drops (Gm. 0.15–0.20), but its topical application is to be preferred.

ZEDOARIA.—ZEDOARY.

Rhizoma zedoariae, P. G.—*Zédoaire*, Fr.; *Zittwerwurzel*, G.

The rhizome of *Curcuma* (*Amomum*, *Willdenow*) *Zedoaria*, *Roscoe*, s. *Curcuma* (*Amomum*, *Koenig*) *Zerumbet*, *Roxburgh*.

FIG. 306.

Nat. Ord.—Zingiberaceæ.

Origin.—The zedoary-plant is indigenous to India and some of the East Indian islands, has long dark-green leaves with a large purple spot in the centre, and produces a short scape bearing a raceme of yellow flowers. The tuberous ovate or pear-shaped rhizome is about $1\frac{1}{2}$ or 2 inches (4–5 Cm.) long, and is usually cut into transverse slices before drying.

Description.—Zedoary is met with in the market in the form of nearly circular disks, varying in diameter from $\frac{1}{2}$ to $1\frac{1}{2}$ inches (1–4 Cm.) It is externally of a grayish-brown color, upon the transverse surface grayish, and has near the edge a dark-colored circular nucleus-sheath. The central portion contains a large number of small orange-colored resin-cells and irregularly scattered wood-

Zedoary: transverse section, magnified 3 diameters.

bundles; both are seen also outside of the nucleus-sheath, though in smaller number. The disks break with a short mealy or somewhat waxy fracture, have a peculiar aromatic odor, and a warm aromatic somewhat camphoraceous taste. The starch-granules are very similar to those of ginger.

Allied Drugs.—The French Codex recognizes long and round zedoary, without giving descriptions, and refers the latter to *Curcuma aromatica*, *Salisbury*. The rhizome of this plant is internally yellow, and may furnish the bright-yellow disks which are occasionally seen among commercial zedoary. The rhizome of several other species is likewise yellow.

Constituents.—Bucholz (1817) obtained from zedoary starch, mucilage, bitter extractive, a pungent soft resin, and volatile oil; the latter is pale-yellow, of a thick consistency, heavier than water, and has a bitterish, pungent, and somewhat camphoraceous taste.

Medical Action and Uses.—Zedoary is usually regarded as being almost identical in its qualities with ginger, but more agreeable, because less burning and acrid. It is used for similar purposes—viz. to promote *digestion*, expel *flatus*, etc. The powder may be prescribed in *doses* of from 10 to 30 grains (Gm. 0.60–2), or an infusion may be made with 3 or 4 drachms (Gm. 12–16) of the bruised root to $\frac{1}{2}$ pint (Gm. 250) of wine or water, and given in tablespoonful doses.

ZINCI ACETAS, U. S., Br.—ACETATE OF ZINC.

Zincum aceticum, P. G.; *Acetas zincicus*, F. Cod.—*Acétate de zinc*, Fr.; *Zinkacetat*, *Essigsaures Zinkoxid*, G.

Formula $\text{Zn}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 2\text{H}_2\text{O}$. Molecular weight 236.9.

Preparation.—Digest for some time Commercial Oxide (or Carbonate) of Zinc 2 parts in Acetic Acid and Distilled Water, each 5 parts; then heat to the boiling-point, filter while hot, and set aside to crystallize. Drain the crystals in a funnel, and dry them upon bibulous paper. An additional quantity of crystals may be obtained by evaporating the mother liquor to one-half, slightly acidulating with acetic acid, and crystallizing. —U. S. 1870, Br.

On digesting oxide or carbonate of zinc with acetic acid, the zinc is dissolved, in the latter case with the evolution of carbonic acid gas; $\text{ZnO} + 2\text{HC}_2\text{H}_3\text{O}_2$ yields $\text{Zn}(\text{C}_2\text{H}_3\text{O}_2)_2 + \text{H}_2\text{O}$. An excess of the zinc compound is used to avoid loss of acetic acid, and is removed by filtration. Should the acetic acid not have been diluted with too large a quantity of water, the hot filtrate, on cooling, will deposit most of the zinc acetate as crystals. The mother-liquor should be evaporated without boiling, so as to avoid loss of acetic acid and the formation of basic salt; acidulating the concentrated mother-liquor with a little acetic acid will restore the normal from the basic acetate, should the latter have been formed. $\text{Zn}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 2\text{H}_2\text{O}$ is the formula recognized by the Br. P.

Properties.—Acetate of zinc crystallizes in soft white pearly six-sided tablets or scales, which on exposure to the air lose their transparency from the evaporation of some acid and water of crystallization, and have a slight acid reaction, a slight acetous odor, and a sharp metallic taste. The salt melts readily in its water of crystallization, and on continuing the heat parts with the latter, the loss amounting to 22.8, which is gradually reabsorbed in a moist atmosphere. On dry distillation acetic acid, carbonic acid gas, acetone, and empyreumatic products pass over, a white pearly sublimate is formed, and oxide of zinc, mixed with a little charcoal, remains behind; when strongly heated in the air upon a porcelain plate, the salt is decomposed, and burns with a greenish light and the production of a white smoke to zinc oxide. At ordinary temperatures the salt dissolves in 3 (2.7 P. G.) parts of water, and in a smaller quantity (1.5 U. S., or 2 parts P. G.) at the boiling-point. It requires about 30 parts (35.6 parts P. G.) of cold alcohol and about 3 parts (U. S.) of boiling alcohol for solution. Treated with sulphuric acid, it is decomposed with the evolution of acetic acid. The aqueous solution of the salt acquires a dark-red color with ferric salts, the color being discharged on the addition of hydrochloric acid, and yields white precipitates with potassium ferrocyanide, hydrosulphuric acid, sulphide of ammonium, ammonia, and potassa, the precipitates with the two last reagents being soluble in an excess of the precipitant, and the colorless solution giving again a white precipitate with hydrosulphuric acid.

Tests.—“The solution of the salt in 10 parts of water should give with an excess of hydrosulphuric acid a purely white precipitate (absence of lead, copper, etc.), and the filtrate on being evaporated should leave no fixed residue (iron, earths, alkalies). On

warming the salt with sulphuric acid it should not turn black (empyreumatic products and other organic matters). Its solution in 3 parts of water should be clear, and should remain clear on the further addition of water (absence of basic salt).—*P. G.* The U. S. P. does not give any tests for organic impurities or basic salt, and directs testing for lead and copper in the acidulated aqueous solution by hydrosulphuric acid, and for iron, aluminium, calcium, etc. by adding to the solution excess of ammonium carbonate, in which the hydrates and carbonates named are insoluble. "On completely precipitating the zinc from this alkaline solution by sulphide of ammonium, the filtrate should leave no fixed residue on evaporation and gentle ignition (salts of alkalies or of alkaline earths)."—*U. S.* If this precipitate, formed in the solution of the salt, has a white color, the test excludes all impurities except aluminium. "The dilute watery solution should not be affected by barium chloride or silver nitrate (sulphate and chloride)."—*Br.*

Medical Action and Uses.—Acetate of zinc acts locally as an irritant and astringent. Internally, in large doses, it occasions vomiting. There is no reason to believe that in any dose it produces poisoning. Internally, it is rarely used in this country. Some years ago it was recommended after this manner by certain German physicians in the treatment of erysipelas and other febrile affections attended with *delirium*, and occasionally it has been employed to check *diarrhœa* in typhoid fever and similar cases. Its chief use, however, is as a local substitutive and astringent application in *conjunctivitis*, *gonorrhœa*, and *leucorrhœa*. For the first-named affection a collyrium may be made with rose-water or mucilage of sassafras-pith in the proportion of about 1 or 2 grains (Gm. 0.06–0.12) of the salt to the fluidounce, to which a few drops of wine of opium may be added. In gonorrhœa and leucorrhœa a customary injection is prepared by dissolving sulphate of zinc and acetate of lead, of each 12 grains (Gm. 0.80), in 8 fluidounces (Gm. 250) of water. The salts react upon one another, producing acetate of zinc and sulphate of lead, the latter of which is precipitated. The value ascribed to this preparation appears to depend partly upon the modifying influence of the insoluble lead salt which sheathes the inflamed parts. When injected the mixture should be shaken. A similar injection is prepared with sulphate of zinc gr. vj; solution of subacetate of lead ℥xxx; water fʒiv.

ZINCI BROMIDUM, U. S.—BROMIDE OF ZINC.

Zincum bromatum, Bromuretum zincicum.—*Bromure de zinc*, Fr.; *Zinkbromid*, G.
Formula ZnBr_2 . Molecular weight 224.5.

Preparation.—This salt is most conveniently prepared by digesting granulated zinc in hydrobromic acid, in which it dissolves with the evolution of hydrogen; the solution (filtered through asbestos or powdered glass) is carefully concentrated, acidulated with a little hydrobromic acid, and dried by the heat of a water-bath.

Properties.—Bromide of zinc crystallizes with difficulty from its aqueous solution, and is therefore usually obtained in the form of a white granular powder. The salt is very deliquescent, has a slight acid (neutral, *U. S.*) reaction, is inodorous, and has a sweet and styptic metallic taste in diluted solution. It is freely soluble in water and in alcohol, and is also soluble in ether. Its aqueous solution yields with silver nitrate a white curdy precipitate, which is insoluble in dilute nitric acid and nearly insoluble in ammonia; it gives white precipitates with potassium ferrocyanide, ammonium sulphide, ammonia, and potassa, the precipitates with the last two reagents being soluble in an excess of the precipitant, and the colorless solution giving again a white precipitate with hydrosulphuric acid. The salt melts on heating, with partial decomposition, to a colorless or yellowish liquid which boils near 700° C. (1292° F.) and sublimes in white needles.

Tests.—"On adding some disulphide of carbon to the aqueous solution, then chlorine-water drop by drop, and agitating, the disulphide will separate with a yellow to brownish-red color, free from violet tint (absence of iodide). 1 Gm. of the dry salt, when completely precipitated by nitrate of silver, yields 1.67 Gm. of dry bromide of silver. (In presence of chloride the precipitate weighs more.) When acidulated with hydrochloric acid, the aqueous solution should yield no dark-colored precipitate with hydrosulphuric acid (absence of lead, copper). On adding test solution of carbonate of ammonium to the aqueous solution, a white precipitate is produced which should be wholly soluble in an excess of the reagent (absence of iron, aluminium, and most alkaline earths). On completely precipitating the zinc from this alkaline solution by sulphide of ammonium the filtrate should leave no fixed residue on evaporation and gentle ignition

(salts of alkalies or of alkaline earths).”—*U. S.* The aqueous solution of the salt should be clear (absence of basic salt), should not be precipitated by barium nitrate (sulphate), and if precipitated by silver nitrate and the mixture rendered alkaline by ammonia, the filtrate, on being acidulated with nitric acid, should merely produce a slight turbidity, but not a curdy precipitate (chloride).

Action and Uses.—It may be conjectured that in proposing this compound as a medicine a vague idea was entertained of its uniting in itself the powers of two medicines, both of which are useful in spasmodic affections, and especially in chorea and epilepsy. That any dose of bromine which can be combined with a suitable dose of zinc should exert a sensible effect is quite improbable. We know of nothing that proves the clinical value of this salt, unless it be the statement that some years ago it was tested at the Salpêtrière in Paris with satisfactory results in the treatment of *epilepsy*. The commencing *dose* of 1 grain daily was increased to 25 grains or more. Had its virtues been proven, it would probably have been heard of again, which has not been the case. Gowers (1880) says of it, “it seemed of small value, and is borne badly.” Its *dose* may safely be that of the oxide of zinc—viz. 1 grain and upward (*Gm.* 0.06).

ZINCI CARBONAS PRÆCIPITATUS, *U. S.*—PRECIPITATED CARBONATE OF ZINC.

Zinci carbonas, Br.; *Hydrocarbonas zincicus*, F. Cod.; *Zincum carbonicum*.—*Sous-carbonate (Hydrocarbonate) de zinc*, Fr.; *Zinkcarbonat*, *Kohlensaures Zinkoxyd*, G.

Formula $(\text{ZnCO}_3)_2, 3\text{Zn}(\text{HO})_2$. Molecular weight 546.5.

Preparation.—Take of Sulphate of Zinc 10 ounces; Carbonate of Soda $10\frac{1}{2}$ ounces; Boiling Distilled Water a sufficiency. Dissolve the carbonate of soda with a pint of the water in a capacious porcelain vessel, and pour into it the sulphate of zinc, also dissolved in a pint of the water, stirring diligently. Boil for 15 minutes after effervescence has ceased, and let the precipitate subside. Decant the supernatant liquor, pour on the precipitate 3 pints of boiling distilled water, agitating briskly; let the precipitate again subside, and repeat the processes of affusion of hot distilled water and subsidence till the washings are no longer precipitated by chloride of barium. Collect the precipitate on calico, let it drain, and dry it with a gentle heat.—*Br.*

The French Codex has adopted a similar process, and directs adding 10 parts of zinc sulphate, dissolved in 50 parts of water, to a boiling solution of 11 parts of sodium carbonate in 50 parts of water, and drying the washed precipitate at 50°C . (122°F .).

On adding cold solutions of sodium carbonate and zinc sulphate together, neutral zinc carbonate is precipitated; $\text{Na}_2\text{CO}_3 + \text{ZnSO}_4$ yields $\text{Na}_2\text{SO}_4 + \text{ZnCO}_3$. The gelatinous precipitate rapidly undergoes decomposition, carbonic acid gas being evolved; and this renders another portion of the precipitate soluble. But if the mixture is boiled, the carbonic acid is expelled from the liquid and the whole of the zinc is precipitated. Adding the solution of zinc sulphate to that of sodium carbonate while boiling hot keeps the precipitate free from sodium compound, and the sulphate of sodium which is formed at the same time is readily removed by washing with water. Carbonate of potassium is not so well adapted for this process as the sodium salt, because the resulting potassium sulphate is less freely soluble in water; and ammonium carbonate is unsuitable, since a complete precipitation of the zinc cannot be effected.

Properties.—Carbonate of zinc is a soft, impalpable, white, inodorous, and tasteless powder, permanent in the air, insoluble in water and other simple solvents, but dissolving readily in acetic and dilute mineral acids, with the evolution of carbonic acid gas, and soluble also in aqueous solutions of ammonium salts. When heated in a crucible to redness it parts with its water and carbonic acid, and leaves about 70 per cent. of oxide of zinc. Its solution in dilute sulphuric acid shows the chemical behavior described under ZINCI SULPHAS.

Composition.—According to H. Rose (1852), this is influenced by the temperature during the preparation and drying of the salt; it contains between 5 and 7ZnO to 2CO_2 , but the proportion of water is more variable. The formula given above is that adopted by the *U. S. P.*, while $(\text{ZnCO}_3)_3, 5\text{Zn}(\text{HO})_2, \text{H}_2\text{O}$ is given by the French Codex.

Tests.—The purity of carbonate of zinc is ascertained by dissolving it in dilute sulphuric acid and testing in precisely the same manner as for sulphate of zinc. The Pharmacopœia directs testing this solution for lead; but sulphate of lead is insoluble in water or diluted acids.

Medical Uses.—Carbonate of zinc is seldom given internally, and its topical appli-

cation is confined to those excoriated or inflamed surfaces which it is desirable to protect from the air and moderately to constrict. Hence in powder it is very useful in healing blisters and other superficial sores which resist milder applications, to prevent the friction that occasions *intertrigo*, and to cure such abrasions when they occur. It is most frequently applied in the form of the official oxide of zinc ointment.

ZINCI CHLORIDUM, U. S., Br.—CHLORIDE OF ZINC.

Zincum chloratum, P. G.; *Chloruretum zincicum*, F. Cod.—*Chlorure de zinc*, Fr.; *Zinkchlorid*, *Chlorzink*, G.

Formula ZnCl_2 . Molecular weight 135.7.

Preparation.—The British Pharmacopœia repeats the directions given for preparing LIQUOR ZINCI CHLORIDI (see p. 938), except that the last filtrate is to be evaporated in a porcelain basin until a portion of the liquid, withdrawn on the end of a glass rod and cooled, forms an opaque white solid; the liquid is then poured into proper moulds, and when the salt has solidified, but before it has cooled, it is placed in closely-stopped bottles.

The reactions occurring in the preparation and purification of chloride of zinc are explained on page 928. Since zinc chloride destroys vegetable fibre and transforms cellulose and starch into soluble modifications, its solution should not be filtered through paper, but through asbestos or powdered glass; otherwise the fused salt will be black. Toward the close of the evaporation of the solution the heat should be regulated so as not to decompose the salt, and in case the fused mass should become opaque from the separation of basic salt a little hydrochloric acid should be added. If the salt is desired for solution in water, the liquid is evaporated and continually stirred until a granular powder remains, a few drops of hydrochloric acid being added toward the close of the process.

Properties.—Chloride of zinc is either in the form of a white crystalline powder or in opaque tablets or rods. It is inodorous, has a strongly caustic and metallic taste, is very deliquescent on exposure, has an acid reaction, and when heated to a little over 100°C . (about $115^\circ \text{C} = 230^\circ \text{F}$., U. S.) it melts to a colorless liquid which congeals to a white mass; at a higher heat it is partly volatilized, forming white fumes and leaves a yellowish residue; but when heated in a current of chlorine gas the salt sublimes in acicular crystals. Chloride of zinc is freely soluble in water, but usually yields with water an opalescent solution from the presence of a little oxychloride, which is readily dissolved by a few drops of hydrochloric acid; the solution dissolves starch, paper, and other organic compounds. Chloride of zinc dissolves also freely in alcohol, and somewhat less freely in ether. In contact with sulphuric acid it is converted into sulphate of zinc. Its solutions yield white precipitates with sulphhydrate of ammonium, ammonia, and with nitrate of silver, the last two being readily soluble in an excess of ammonia. On mixing a concentrated solution of zinc chloride with oxide of zinc a plastic mass of oxychloride of zinc is obtained, which soon hardens.

Tests.—The solution of chloride of zinc in water acidulated with hydrochloric acid should remain clear (absence of lead), and should not yield a dark-colored precipitate with sulphuretted hydrogen (lead, copper, etc.). With an excess of ammonium carbonate a clear solution should be obtained (aluminium, iron, calcium, etc.), which should not be precipitated by a drop of phosphoric acid (magnesium), and which yields with sulphuretted hydrogen or sulphide of ammonium a white precipitate, the filtrate from which, on being evaporated and ignited, should leave no fixed residue (potassium, sodium). The U. S. P. requires that the aqueous solution of this salt should be miscible with alcohol without precipitation (absence of basic salt); yet it permits the salt to form with water a faintly opalescent liquid, the opalescence to be removable by a few drops of hydrochloric acid. The P. G. more correctly permits the presence of a little oxychloride, and requires the salt to form a clear and colorless solution with an equal weight of water; on the addition of 3 parts of alcohol a flocculent precipitate may form which should dissolve on adding 1 drop of hydrochloric acid.

Pharmaceutical Uses.—CAUSTICUM CUM CHLORURETO ZINCICO, F. Cod.—Chloride of zinc pencils, E.; Pâte de Canquoin, Fr.—Dissolve chloride of zinc 32 Gm. in cold distilled water 4 Gm.; add oxide of zinc 8 Gm., previously mixed with well-dried wheat flour 24 Gm.; triturate so as to obtain a paste, and form this into cylinders or other shaped pieces, which are to be completely dried in an air-bath at a temperature gradually raised from 50° to 100° (122° – 212°F .).

Physiological Action.—In small and properly-adjusted doses chloride of zinc is said to act as a stimulant and tonic to the nervous system and increase the urinary secretion, but the grounds of these statements are more than equivocal. In large doses it is a powerful irritant poison, occasioning pain in the stomach, nausea, vomiting, anxiety, quick and short breathing, a small and rapid pulse, cold sweats, syncope, and convulsions. Generally, after death, the mucous membrane of the throat and œsophagus, if not of the mouth, is found abraded, and the coats of the stomach are disorganized and converted into a leathery substance. The body shows no signs of putrefaction.

Applied externally, it is powerfully corrosive, and, although very painful, is perhaps less so than corrosive sublimate or arsenic. Its first application produces a sense of warmth and more or less redness. Upon the denuded skin its action is more rapid as well as more painful, but it does not extend beyond the limits of the caustic. If it is made to penetrate deeply, it coagulates the blood in the vessels and converts the soft tissues into a tough, dry, and uniform mass which is not fetid, and which separates in from one to two weeks, leaving behind a clean granulating surface that tends to rapid cicatrization.

Medical Uses.—The rare occasions in which chloride of zinc may be given internally have been already pointed out. (See LIQUOR ZINCI CHLORIDI.) In the same connection its uses as a disinfectant were noticed. When, owing to the timidity of patients or any other cause, the knife cannot be employed for the removal of *malignant* and other *morbid growths*, this preparation is preferred before other caustic applications, because it runs no risk of poisoning the system, and because its action is limited to the points of its contact with the tissues. It was originally alleged to be much more successful than excision in the treatment of cancer, and, indeed, to have cured four-fifths of the cases in which it was employed; it was also thought to possess the advantage of acting on the diseased rather than on the healthy tissues. These conclusions have been proved groundless, as well as the allegation that the pain produced by the application is inconsiderable. On the contrary, the pain caused by chloride of zinc far exceeds that occasioned by the knife, even without the use of anæsthetics, and is of much longer duration. To what degree this caustic is capable of preventing a return of cancerous disease is still undetermined. It is very positively alleged by competent authorities that the recurrence of cancerous tumors is due mainly to their incomplete extirpation by excision, and that this and some other caustics reach and destroy the cancerous germs more effectually than a surgical operation.

The mode of action here attributed to chloride of zinc was long since pointed out by Bonnet. He remarked that when applied as a paste in the neighborhood of large blood-vessels, arteries, or veins, its caustic action does not occasion hæmorrhage, but under its influence they contract and shrivel, and only remain as thin, hard, and apparently solid strings. The experiments of Gersuny and Gjorgjevié on dogs and rabbits exhibited a similar result, for even when the chloride was applied to wounds in which large veins were exposed the vessels were not penetrated, there was no hæmorrhage, and their walls collapsed and shrivelled. In 1878, Dr. Carl Langenbuch treated a case of *rodent ulcer*, or of *lupus exedens*, affecting the face and neck and laying bare the large blood-vessels of the cervical region—a case in which instrumental interference was out of the question—by means of chloride of zinc, with the result of arresting the ulceration, suspending the circulation through the exposed vessels, and securing a perfect cure. He also refers to a similar treatment of gangrenous ulcers in the Franco-German War of 1870–71. In these cases the pure chloride was applied in the manner described below as Cooke's. It appears, therefore, that the action of this compound is not properly a caustic action; it mummifies the tissues, but does not destroy them.

Several modes of applying chloride of zinc as a caustic have been employed. The oldest is that of Canquoin, who made use of a paste containing 1 part by weight of the chloride to 2, 3, 4, or 5 parts of rye flour; or 5 parts of the chloride and 10 of rye flour made into a paste with 2 parts of glycerin may be used. Gluten has been used as an excipient instead of flour. Mayet's paste is made as follows: Chloride of zinc 8 parts; oxide of zinc 1 part; wheaten flour, dried at 212° F., 7 parts; water 1 part. Mix the oxide of zinc and the flour, dissolve the chloride of zinc in the water, and add to the solution the mixture of oxide of zinc and flour. Rub the paste in a mortar for ten minutes. Cooke's method consists in saturating lint with the deliquesced salt, and keeping it, after it is dried, in a close box of wood or pasteboard. The lint when used must be cut with scissors that can be spared, since it ruins steel instruments. A convenience of this preparation is that it can be applied in pieces proportioned to the size of the part to be

acted upon. A similar advantage is possessed by a mixture of chloride of zinc and gutta-percha in equal parts; its caustic action is attenuated by the inert and insoluble portion of it. Conical or arrow-shaped bodies made with chloride of zinc alone, or of this salt and nitrate of potassium, are sometimes thrust into incisions made in the tumor to be acted upon. Before applying any of these mixtures the cuticle, if unbroken, must be removed by means of strong ammonia. In 1879 cases of *nasal polypi* were cured by injecting the tumors with chloride of zinc, and in the following year several others were reported (*Archives gén. de Med.*, Mars, 1880, p. 353; *Med. Record*, xviii. 433). In 1881 additional cases were furnished by Dr. Reynolds of Kentucky (*Trans. Amer. Med. Assoc.*, xxxii. 237). The stronger preparations have been used to destroy anastomotic *aneurisms* and to open *abscesses* where puncture or incision might be dangerous, as abscesses of the liver. Chloride of zinc has been applied to destroy the hardened tissues surrounding cavities and fistule following the suppuration of *scrofulous glands*, and is said to possess the advantage over other methods of local treatment of not leaving behind it irregular or unsightly scars. It has also been employed to fill the cavities of *carious teeth*, especially of the incisors.

ZINCI IODIDUM, U. S.—IODIDE OF ZINC.

Ioduretum zincicum.—*Iodure de zinc*, Fr.; *Zinkjodid*, G.

Formula ZnI_2 . Molecular weight 318.1.

Preparation.—This salt may be prepared by dissolving oxide or carbonate of zinc in hydriodic acid, or, according to Doepp (1839), by digesting in a flask 3 parts of granulated zinc, 10 parts of iodine, and 20 parts of water until the liquid has become colorless, when it is filtered through asbestos or powdered glass, and rapidly evaporated to dryness at a moderate heat. The yield is $12\frac{1}{2}$ parts. The salt should be at once put into vials, which are to be kept carefully stopped.

Properties.—Iodide of zinc resembles the chloride and bromide of zinc, is a white granular, crystalline, inodorous powder, and has a caustic and metallic or in diluted solution a sweetish and styptic taste and an acid reaction. On exposure it is very deliquescent, and gradually becomes colored by, and acquires the odor of, free iodine. It is freely soluble in water and alcohol, and the solution on being largely diluted with water separates a gelatinous precipitate of hydrate of zinc (Rammelsberg). It readily forms basic compounds, an oxyiodide soluble in warm and insoluble in cold water being produced by the prolonged digestion of iodine and zinc with water. The iodide melts when carefully heated to a colorless liquid, and may be sublimed in quadrangular needles, but on being heated in the air is decomposed into iodine and zinc oxide. The aqueous solution gives white precipitates with ammonium sulphide, potassium ferrocyanide, ammonia, and potassa, the last two being soluble in an excess of the precipitants, and it yields a scarlet-red precipitate with mercuric chloride, a bright-yellow one with lead acetate, and a pale-yellow one with silver nitrate, the latter being insoluble in ammonia and in nitric acid. The salt, warmed with strong sulphuric acid, liberates iodine and sulphur dioxide, zinc sulphate being formed at the same time.

Tests.—The absence of foreign metals is ascertained in precisely the same manner as in chloride and bromide of zinc, and the absence of sulphate by the solution not producing a precipitate with barium chloride. The absence of other zinc salts may be ascertained as follows: "1 Gm. of the dry salt, when completely precipitated with nitrate of silver, yields 1.47 Gm. of dry iodide of silver."—U. S. Bromide and chloride, if present, increase the weight of the silver precipitate. The test as given proves the absolute purity of the salt, the weight theoretically obtainable being 1.473 Gm. This seems to be too strict a requirement, in view of the alterations taking place on exposure. Hager suggests the following test, which requires at least 95 per cent. of pure ZnI_2 : 0.5 Gm. of the dry salt should yield with 5 Gm. of alcohol a nearly clear solution free from crystalline deposit; add to this liquid 0.6 Gm. of silver nitrate dissolved in 30 Gm. of water, afterward 5 Gm. of ammonia-water, agitate well, and filter; the precipitate when dried should weigh not less than 0.7 Gm., and the filtrate on being acidulated with nitric acid should remain clear or at most become faintly opalescent, but should not produce a curdy precipitate.

Pharmaceutical Preparation.—*SYRUPUS ZINCI IODIDI*. Syrup of iodide of zinc. Digest 2 troynounces of iodine and 5 drachms of granulated zinc in 8 ounces of water, and when the color of iodine has disappeared pass the liquid through a small filter into a bottle containing 15 troynounces of sugar; wash the filter with a little water and dissolve

the sugar by agitation. The syrup should measure 20 fluidounces, and is of about the same iodine strength as the syrup of iodide of iron (A. B. Taylor, 1852). This is the most convenient form for the administration of iodide of zinc.

Medical Uses.—As long ago as 1853 this compound was recommended in hysterical chorea (*Lancet*, Dec. 1853, p. 624), and externally in various scrofulous affections of the skin and eyes (Guibert, *Nouveaux Médicaments*, 1864). It was used by Lente as an application to the Eustachian tube in certain cases of deafness (*Amer. Jour. of Med. Sci.*, Oct. 1859, p. 390), and by Ross as an application to enlarged and indurated tonsils. A solution of 1 or 2 grains in an ounce of water (Gm. 0.06–0.12) has been employed as an injection in gonorrhœa and leucorrhœa. It seemed to be entirely obsolete when it was revived in the Pharmacopœia of 1880. Its dose is said to be from half a grain to 2 grains (Gm. 0.03–0.12).

ZINCI OXIDUM, U. S., Br.—OXIDE OF ZINC.

Zincum oxydatum, P. G.; *Oxydum zincicum*, F. Cod.; *Flores zinci*.—*Oxyde de zinc*, Fr.; *Zinkoxyd*, G.

Formula ZnO . Molecular weight 80.9.

Preparation.—Place carbonate of zinc in a loosely-covered Hessian crucible, and expose it to a dull red heat until a portion, taken from the centre of the contents of the crucible and cooled, no longer effervesces when dropped into diluted sulphuric acid. Let the crucible cool, and transfer the product to stoppered bottles.—Br.

Nearly identical is the process of the French Codex for *oxyde de zinc par voie humide*. When heated, carbonate of zinc parts with its water and carbonic acid, leaving oxide of zinc behind. The operation is known to be finished when a small portion, taken from the centre of the vessel and mixed with a little water, no longer produces effervescence on being dropped into dilute sulphuric acid. A dull red heat, as directed by both pharmacopœias, is not necessary for this purpose. Mohr observed that a temperature of 280°C . (536°F .) is sufficient for obtaining the oxide, and, according to Hager, all carbonic acid is expelled at 250°C . (482°F .). With quantities of from 6 to 12 ounces of carbonate of zinc the operation is conveniently performed in a glass flask placed in a sand-bath and heated by means of gas or on a stove. The capacity of the flask should be about double the volume of the powdered carbonate. If the carbonate of zinc is not previously powdered, a higher heat and a longer time are required for expelling all the carbonic acid. If the carbonic acid be driven off below a red heat, or if the heating to dull redness has not been prolonged unnecessarily, the cold zinc oxide has a white color, but after having been exposed to a full red heat it will retain after cooling a more or less decided yellow tint.

The French Codex recognizes also an *oxyde de zinc par voie sèche*, which is made by melting pure zinc in an inclined crucible in contact with air to a bright-red heat, when it takes fire and burns to oxide, which condenses in the upper part of the crucible or in suitable vessels suspended over it, and after cooling is passed through a fine sieve. The same product, though less pure, was recognized by the U. S. P. 1870 as ZINCI OXIDUM VENALE (Zinc-white); *Zincum oxydatum crudum*, P. G.; *Flores zinci*, Pompholix, Nihil album, Lana philosophica. This was recommended by Courtois (1780) as a pigment in place of white lead, but began to be used as such since about 1844, after Leclair had elaborated a process for making it at a sufficiently low rate. At present it is usually prepared directly from zinc ores by processes identical with or similar to those recommended by W. J. Taylor (1861) and G. Darlington (1862). A mixture of zinc ore and coal is packed in a suitable furnace upon a layer of coke, previously ignited and heated by means of a blast, and the vapors of oxide of zinc, which are at first more or less mixed with particles of charcoal, are conducted into a chamber, where they condense as a gray powder. As soon as the condensing product has a white color the vapors are passed into another chamber, where they condense as zinc-white. The gray product is identical with the impure oxide of zinc, which was formerly used in medicine under the names of *tutia*, *cadmia fornacum*, or *tutty*.

Properties.—Oxide of zinc is a soft, inodorous, and tasteless, pale-yellowish, nearly white powder, which on being heated acquires a deep lemon-yellow color, and on cooling becomes again nearly white. After having been heated to bright redness it continues for some time to emit light in the dark. It dissolves in dilute acetic and other acids without effervescence, is completely insoluble in simple solvents and in saccharine liquids, and is without action on test-paper. According to Daubrée, it may be obtained crystallized by

heating chloride of zinc in a current of steam. On exposure to the atmosphere it slowly absorbs water and combines very gradually with carbonic acid.

Tests.—Oxide of zinc may contain traces of chloride or sulphate, which are detected in the solution in dilute nitric acid by nitrate of silver and nitrate of barium. The liquid obtained on boiling oxide of zinc with water and filtering should not have an alkaline reaction from the presence of carbonate of sodium. The solution of the oxide in hydrochloric acid should not assume a red color on the addition of sulphocyanide of potassium (iron), should not be colored or precipitated by sulphydric acid (lead and similar metals), and should be completely precipitated with a white color by sulphhydrate of ammonium; the filtrate from this precipitate, after having been boiled, should not be disturbed on the addition of oxalate of ammonium (calcium) or of phosphate of ammonium (magnesium). The U. S. P. does not give any tests for acidulous radicals, and directs testing for foreign bases after dissolving the oxide in diluted sulphuric acid in the same manner as directed for sulphate of zinc; this solution cannot contain lead, though the Pharmacopœia mentions it among the possible impurities. Zinc-white should respond to the same tests, but a minute proportion of lead is permitted by the P. G. by the following test, which fails to detect about $\frac{1}{2}$ per cent. of PbO: Dissolve 0.2 Gm. of the zinc oxide in 2 Gm. of acetic acid; after cooling, the solution should not be affected (become yellow and turbid) on the addition of potassium iodide.

Off. Prep.—Unguentum zinci oxidi (zinci), U. S., Br.

Physiological Action.—It is conjectured that oxide of zinc, when received into the stomach, is converted into an albuminate if sufficient food or mucus is contained in the organ, and that otherwise it acts as a local irritant, and even as a caustic. However this may be, it is certain that when continuously given to rabbits in large doses it causes erosion and ulceration of the stomach, and ultimately wasting of the flesh. In experiments upon healthy men it has been found that repeated doses of 4 grains or more of this salt occasioned nausea, eructation, vomiting, confusion of the mind and senses, heat in the epigastrium, thirst, fever, a jerking pulse, muscular spasm, etc. Sometimes, when prescribed in very large and continued doses, it has produced marasmus, œdema of the feet, diarrhœa, etc. These and similar effects are arrested by suspending the medicine, but even when it has been continuously given in doses of 20, 40, or even more grains a day, such symptoms have rarely arisen. That, however, they are really due to the poisonous action of zinc is proved by the manner in which smelters of the metal are affected—viz. with cough, dyspnœa, and even hæmoptysis, or dyspeptic symptoms, vomiting, and diarrhœa, loss of flesh, neuralgia, muscular spasm, and debility. Besides these symptoms are observed a gradual anæsthesia of the skin, diminished reflex excitability, muscular tremors, especially of the legs; in a word, the signs of disorder of the spinal marrow (Schlochow, *Monthly Abstract*, Mar. 1880, p. 158).

Medical Uses.—Oxide of zinc has been used in medicine chiefly for the cure of nervous diseases, and long before the experiments above referred to denoted its special mode of action; for it was introduced by Paracelsus, and proposed as a remedy for epilepsy by Gaubius, who learned its virtues from a charlatan. Many physicians have claimed for it a curative virtue in *epilepsy*, and among them some whose names have the weight of authority; nevertheless, a rigid scrutiny of facts has proved that this medicine never cures, and seldom even palliates, the disease. In six out of twenty cases under the care of Russell a decided impression was made on the course of the disease by the zinc given to the extent of 18 grains three times a day (*Practitioner*, xxx. 83). The utility of oxide of zinc is still less in *chorea*, a disease which as naturally tends to cure as epilepsy is rebellious to all treatment that is not merely palliative. The utility of the medicine in these affections is claimed by some physicians who have used it along with the bromides! Such a confusion of ideas is a fruitful source of error in therapeutics. Oxide of zinc has also been used with alleged benefit in *hysteria* and *spasmodic asthma*. In the nervous state consequent upon *delirium tremens*, and in *chronic alcoholism* attended with want of sleep, trembling, vertigo, tinnitus aurium, muscæ volitantes, and occasional hallucinations, it sometimes is very beneficial. In such cases it may be given in doses of 2 grains (Gm. 0.12) three times a day, and gradually increased. There is little doubt that this medicine is one of the best for colliquative *sweats*, although it sometimes fails, and is not superior to the sulphate of zinc. It should be prescribed in 1-grain (Gm. 0.06) doses every hour for three or four hours in the evening. Murrell recommends that it be given "at bed-time in from 5- to 10-grain doses, made up into pill with extract of henbane or conium" (*Practitioner*, xxiii. 91). Such doses appear to us fitted to produce vomiting and even poisonous effects. In *diarrhœa* and *dysentery* it was recommended by J. Waring-Curran

(1868) as being their best and most speedy cure. Some time later it was advised by Gubler in diarrhœa, and in imitation of him by Bonamy (1876), who employed it successfully when other remedies had failed in an epidemic of dysenteric diarrhœa. He mixed 50 grains of oxide of zinc with 10 grains of bicarbonate of sodium (Gm. 3.50 and Gm. 0.66), and divided the mixture into three or four parts, which were administered during the day at intervals of three hours. The effect of the medicine is said to have been prompt and decisive even in the most chronic cases. This conclusion was subsequently confirmed in Scotland by Brakenridge and by Renton (1877), and by Jacquier in France (1878). In infantile diarrhœa it was given to a child of six months in doses of 2 grains (Gm. 0.12) every two hours. In this country it was used with advantage by James L. Tyson, although sugar was associated with it, which Renton found to impair its efficiency. Associated with belladonna, it is more efficient than is either medicine alone. Oxide of zinc with valerian in large and increasing doses is said to have cured *diabetes insipidus* (*Amer. Jour. Med. Sci.*, Jan. 1882, p. 276). In fine powder it forms an admirable application for promoting the healing of *intertrigo*, superficial burns and scalds, fissures of the nipples or anus, *balano-posthitis*, flabby ulcers, *leucorrhœa*, and moist eruptions of the skin. For some of these purposes it may be mixed with powdered starch, acacia, or lycopodium. The officinal ointment is used for similar purposes. The following preparation has also been recommended: Glycerin 16 parts, starch 8 parts, oxide of zinc 4 parts. Warm the glycerin and starch in a porcelain capsule until they form a jelly, and then stir in the oxide of zinc.

Oxide of zinc may be administered in powder or in pill, and in doses of from 1 to 5 grains (Gm. 0.06–0.30). It is best given after meals.

OLEATE OF ZINC made into an ointment with 1 part of vaseline or olive oil, or 2 parts of lard or simple ointment—vaseline being preferable, as not liable to change—has been used with excellent results in the treatment of *eczema*, especially during the stage of active secretion (Crocker, 1879).

Commercial oxide of zinc may be used in powder as an external application in the various local affections mentioned above, to diminish secretion and protect parts from the action of the air.

ZINCI PHOSPHIDUM, U. S.—PHOSPHIDE OF ZINC.

Phosphoretum zincicum, F. Cod.—*Phosphoret of zinc*, E.; *Phosphure de zinc*, Fr.; *Phosphorzink*, G.

Formula Zn_3P_2 . Molecular weight 256.7.

Preparation.—If zinc is fused in a crucible, and phosphorus is added in small pieces at a time, the crucible being kept covered as much as possible, a union of the two elements takes place, but it is difficult to obtain the compound of uniform composition. According to Schrötter (1849), finely-divided zinc is heated to dull redness while the vapor of phosphorus is being passed over it. Vigier's modification of this process consists in heating the zinc in a current of hydrogen; after all atmospheric air has been expelled vapors of phosphorus are passed over the zinc. On account of the great danger connected with this process, owing to the liability to violent explosions, Proust (1869) proposed the following process: Nitrogen gas is evolved by heating nitrite of ammonium, and the gas is passed through a bottle in which phosphoretted hydrogen is prepared by introducing phosphide of calcium through a wide tube into diluted hydrochloric acid contained in the bottle. The mixed gases are passed through a wash-bottle into a porcelain tube in which zinc is heated to redness, when the metal will combine with the phosphorus and the liberated hydrogen will escape together with the nitrogen. If the apparatus is filled with nitrogen gas before phosphoretted hydrogen is generated, there is no danger of an explosion.

Properties.—Phosphide of zinc is stated to be permanent in the air, but the slight phosphorus odor emitted by it indicates its gradual oxidation; it should therefore be preserved in well-stopped vials. It forms a gray crystalline or friable mass, having upon the fractured surface a bright metallic lustre. Vigier (1875) recommends it to be powdered and freed by sifting from metallic zinc which may be present; in this state it resembles iron reduced by hydrogen, has a blackish-gray color and a slight taste of phosphorus, is readily soluble in dilute sulphuric or hydrochloric acid, with the copious evolution of phosphoretted hydrogen, and by concentrated nitric acid is converted into zinc phosphate. It melts at a higher temperature than zinc, and volatilizes unchanged, con-

densing in needles if the air be excluded; but when heated in contact with air it is oxidized to zinc phosphate.

Composition.—Pure phosphide of zinc consists of 24.12 per cent. of phosphorus and 75.88 per cent. of zinc.

Tests.—"1.171 Gm. of phosphide of zinc in contact with official hydrochloric acid should evolve 200 Ccm. of phosphoretted hydrogen, which should be completely absorbed by a concentrated solution of copper sulphate."—*F. Cod.* This test proves the absence of metallic zinc, which would evolve hydrogen; phosphoretted hydrogen produces in the copper solution a black precipitate of phosphide of copper. The U. S. P. directs testing only for foreign metals after dissolving the compound in diluted sulphuric acid; such a solution is free from lead, the possible presence of which is assumed by the Pharmacopœia.

Physiological Action.—Phosphide of zinc in the dose of 1 grain is sufficient to kill a rabbit weighing 7 pounds, and dogs treated with this compound for the purpose of producing fatty degeneration of the liver all died when the dose reached 1½ grains. "It contains one-fourth of its weight of phosphorus, and yet its toxical action represents a strength of only one-eighth. Or 8 Mgm. of the phosphide are equivalent to 1 Mgm. of the phosphorus in activity. The reason of this difference is that the phosphide is decomposed by the muriatic acid of the stomach, and one-half of the product becomes hypophosphide of zinc, whose action in small quantity is negative; and the remainder is converted into chloride of zinc and phosphoretted hydrogen" (Vigier). Pills containing ½ gr. of phosphide of zinc are said to occasion slight alliaceous eructations, which are more marked if this dose is exceeded, and it is alleged that ⅔ gr. may be used without greater inconvenience. Indeed, Vigier states that, having taken 1½ gr. of the phosphide in a single dose, he only experienced a transient gastric oppression, but that on the following day a like dose caused vomiting. In numerous cases two pills, each containing ⅓ gr. of the phosphide, have occasioned excessive diarrhœa, gastric oppression, anorexia, alliaceous eructations, and rectal discharges. In other and more numerous cases the medicine is well tolerated, especially when taken some time before meals.

Medical Uses.—Phosphide of zinc has been used principally in nervous disorders attributed to defective nutrition of the brain and spinal marrow. Among these *locomotor ataxia* and *general paralysis* are especially to be mentioned. It is alleged that in certain cases of the former affection co-ordination of the movements has been restored and the evidences of sexual power revived; but the paucity of reports of its success in a disease which is ordinarily rebellious to all medicinal treatment would argue badly in its favor, even if its total want of curative power in other cases of the same disease were not well established. An almost identical statement may be made respecting the other affection mentioned, for only one or two cases of paralysis, ascribed to disseminated sclerosis of the cord, and an equal number of cases of *mercurial tremor*, are recorded in which any advantage appears to have been derived from the medicine. A very similar summary may be given of its effects in *anaphrodisia*. Several persons have published accounts of its curative virtues in *neuralgia*, *spinal irritation*, *hysteria*, and *cerebral disorders*, with an excessive elimination of phosphates with the urine, in *chlorosis*, *anæmia*, *amenorrhœa*, *dysmenorrhœa*, and *metrorrhagia*. But these reports, dating as far back as 1868, have not been sufficiently confirmed. Mercier (1878) found this medicine very useful in neuralgia, capable of retarding the progress of locomotor ataxia, almost certain in relieving anaphrodisia, and efficient in dysmenorrhœa and amenorrhœa. But they do not accord with general experience. It was claimed (1874) to be an efficient remedy for the neuralgic pains of *herpes zoster*, but the claim has not been confirmed.

Phosphide of zinc may be given in the dose of ⅙ to ½ gr. (Gm. 0.004–0.008), which is estimated to equal ⅓ to ⅔ gr. of phosphorus, but some of those who have most recommended it direct doses of ⅓ gr. (Gm. 0.02) every two hours. It may be prescribed in pills with liquorice powder and syrup or in powder with starch. It is suggested that it be given when the stomach does not contain food, as being then less apt to disengage phosphoretted hydrogen.

Dr. R. W. Gardner has objected to phosphide of zinc that, as no oxygen enters into its composition, it must produce in the stomach the same irritant effects as uncombined phosphorus. He therefore proposes in its stead the *hypophosphite of zinc*, as not irritant and as admitting the use of such doses as fully to meet all indications for either phosphorus or zinc. The salt is perfectly soluble, and therefore readily absorbable. Its administration is recommended in a syrup containing 8 grains of the salt to a fluidounce, of which a teaspoonful is suggested as an average dose.

ZINCI SULPHAS, *U. S., Br.*—SULPHATE OF ZINC.

Zincum sulfuricum, P. G.; *Sulfus zincicus*, F. Cod.; *Vitriolum album*.—White vitriol, E.; *Sulfate de zinc*, *Vitriol blanc*, *Couperose blanche*, Fr.; *Zinksulfat*, *Schwefelsaures Zinkoxyd*, *Weisser Vitriol*, *Galitzenstein*, G.

Formula $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$. Molecular weight 286.9.

Preparation.—Take of Granulated Zinc 16 ounces; Sulphuric Acid 12 fluidounces; Distilled Water 4 pints; Solution of Chlorine a sufficiency; Carbonate of Zinc $\frac{1}{2}$ ounce or a sufficiency. Pour the sulphuric acid, previously mixed with the water, on the zinc contained in a porcelain basin, and when effervescence has nearly ceased aid the action by a gentle heat. Filter the fluid into a gallon bottle, and add gradually, with constant agitation, the solution of chlorine, until the fluid acquires a permanent odor of chlorine. Add now, with continued agitation, the carbonate of zinc until a brown precipitate appears; let it settle, filter the solution, evaporate till a pellicle forms on the surface, and set aside to crystallize. Dry the crystals by exposure to the air on filtering-paper placed on porous tiles. More crystals may be obtained by again evaporating the mother-liquor.—*Br.*

Zinc dissolves in dilute sulphuric acid with the evolution of hydrogen, forming sulphate of zinc; $\text{Zn}_2 + 2\text{H}_2\text{SO}_4$ yields $2\text{ZnSO}_4 + 2\text{H}_2$. Arsenic, copper, and lead, which are sometimes present in commercial zinc, are removed by the continued digestion with an excess of the metal, as ordered in the above process; but iron will dissolve, together with the zinc, to ferrous sulphate. This is converted into ferric salt by chlorine-water, and ferric hydrate is now precipitated on agitating the liquid with precipitated oxide or carbonate of zinc. The filtered liquid is free from the metals named, and on being sufficiently concentrated will yield crystals of pure sulphate of zinc.

The same salt is economically prepared on the large scale from zinc-white, or by roasting the native sulphide of zinc, ZnS , called *blende*, whereby this compound is oxidized to sulphate; this is extracted with hot water, and the clear solution, evaporated, yields *crude white vitriol*, which should be purified by redissolving it in water, boiling with zinc, treating with chlorine and carbonate of zinc, filtering, and evaporating to crystallization; magnesium and alkali sulphates are not removed by this treatment. The importation of white vitriol into the United States has increased from 10 pounds in 1878 to 577,304 pounds in 1883.

Properties.—Sulphate of zinc crystallizes readily in large transparent rhombic prisms, which are isomorphous with those of sulphate of magnesium. As seen in commerce, it is in small prisms or prismatic needles, obtained by disturbed crystallization from concentrated solutions. On exposure the crystals become slowly opaque from the loss of water of crystallization, of which 6 molecules, or 37.6 per cent., are given off at 100°C . (212°F .); the last portion, amounting to 6.3 per cent., is expelled at a low red heat or at 110°C . (230°F .) in a current of dry air. Sulphate of zinc is inodorous and has a strongly styptic and nauseous metallic taste and an acid reaction. According to Poggiale, 1 part of the crystallized salt dissolves

at	10°	20°	30°	50°	100°C .
in	.724	.620	.585	.380	.153 parts of water.

The pharmacopœias give the solubility for 1 part of the salt at 15°C . (59°F .) in 0.74 part (*F. Cod.*), 0.6 part (*U. S., P. G.*), and at 100°C . in 0.3 part (*U. S.*) 0.15 part (*F. Cod.*) of water; also in .86 part of glycerin (*F. Cod.*). Supersaturated solutions are easily obtained, particularly in contact with air which has been previously filtered through cotton. 100 parts of 40 per cent. alcohol dissolve, according to Schiff, only 3.48 parts of the salt, and in strong alcohol it is insoluble. The aqueous solution of sulphate of zinc yields white precipitates with chloride of barium, with sulphide of ammonium, and with ferrocyanide of potassium.

Tests.—Commercial or crude zinc sulphate is not sufficiently pure for medicinal purposes; it contains iron, occasionally also copper, aluminium, and calcium sulphate, and sometimes cadmium. These salts and the alkali sulphates cannot be removed by recrystallization. Lead cannot be present in this salt if completely soluble in water, owing to

FIG. 307.

Crystals of Zinc Sulphate.

the insolubility of its sulphate; yet the Pharmacopœia mentions it among the possible impurities. If a large proportion of chloride be present the salt will be hygroscopic; the Pharmacopœia permits a trace of this impurity, so that a 1 per cent. solution of the salt, acidulated with nitric acid, should not be rendered turbid by nitrate of silver. Other possible impurities are detected as follows: The aqueous solution, on being acidulated with hydrochloric acid and treated with sulphuretted hydrogen, should yield neither a yellow, brown, nor black coloration or precipitate (cadmium, arsenic, copper, and similar metals). In case iron be present the solution will afford with a little ferrocyanide of potassium a more or less deep-blue precipitate. An excess of ammonia added to the aqueous solution should yield a clear and colorless liquid, in the presence of copper the color of the solution would be blue, and iron and aluminium would remain undissolved. The solution of the salt, after having been precipitated by sulphide of ammonium, or the ammoniacal solution after treatment with sulphuretted hydrogen, yields a filtrate which on evaporation to dryness and ignition should leave no fixed residue (potassium, sodium, magnesium, and calcium). Ammonium sulphate is detected by the ammoniacal odor given off on the addition of an excess of potassa or soda. Nitrate is detected by adding to the solution sulphuric acid, test zinc, gelatinized starch, and a little potassium iodide, when the nascent hydrogen will cause the reduction of nitric to nitrous acid, and the latter will liberate iodine, causing a blue color with the starch.

Composition.—Sulphate of zinc has the formula given above, and contains 43.9 per cent. of water, 28.22 per cent. of oxide of zinc, and 27.88 per cent. of SO_2 . The sulphate may also be obtained with less water by crystallizing from its solution above 30°C . (86°F).

Off. Prep.—Zinci carbonas, Zinci valerianas, Br.

Physiological Action.—This salt in a certain proportion coagulates liquid albumen, but in excess redissolves it. It acts upon mucous membranes as an irritant, but not as a true caustic, for it hardens but does not destroy the tissues. Internally, in doses of from 6 to 12 grains, it occasions vomiting, and sometimes purging. Very large doses produce a styptic taste in the mouth, constriction of the fauces, pain in the stomach and bowels, retching, violent vomiting, purging, distress, thirst, a slow and contracted pulse, slow respiration, cold extremities, spasms, and sometimes death. This last result is, however, of rare occurrence. In no case is the mind affected. Even 4 ounces of the salt in 5 ounces of water are said to have been taken for Epsom salts without causing death (*Lancet*, July, 1865, p. 52). In a fatal case death did not occur before the fifth day, and the only lesions found were some red patches near the pyloric end of the stomach and in the duodenum (*Times and Gaz.*, Sept. 1862, p. 262). The secondary effects of the medicine, or those which result from its absorption, are more or less astringent, tonic, and antispasmodic.

Medical Uses.—Externally and locally, sulphate of zinc acts as a stimulant astringent; it is commonly applied to quicken vital action as well as to check secretion. It enters into a paste which is very useful in *canerum oris*, and contains besides extract of cinchona, catechu, and honey of roses. A similar preparation is to be recommended for *aphthæ*. In *conjunctivitis* and in *gonorrhœa*, in the forming stage, or again on the decline, a solution may be employed containing about 1 grain of the salt to an ounce of water (Gm. 0.06 in Gm. 32). In *ophthalmia neonatorum* the following has been used as a collyrium: $\mathcal{R}$. Sulphate of zinc gr. xx; water f5x; solution of subacetate of lead f5ss; tincture of camphor f5i-ij. A small portion of this solution may be injected between the eyelids several times a day. A solution applied with a brush or sponge to the *throat* or *larynx* should not exceed the strength of 10 grains to the ounce; an atomized solution for inhalation may contain 1 or 2 grains to the ounce (Gm. 0.06 to Gm. 32). In the first-named form it is useful in commencing inflammation of the fauces. To arrest *hemorrhage* it is often used in solution and injected into the bladder, uterus, rectum, or nostrils, though for all except the first-mentioned case it is more efficient when applied upon a sponge. In powder this salt has been employed by insufflation in the treatment of *polypi* of the nostrils, and in solution applied to the seat of these growths after evulsion and to prevent their reproduction. Sir J. Y. Simpson recommended a paste containing 120 grains of lard to an ounce of the sulphate (Gm. 8 to Gm. 32), or a glycerate made with 40 grains of glycerin to the same quantity of the sulphate (Gm. 2.60 to Gm. 32), for the treatment of ulcers and soft *tumors* about the vagina, anus, etc., which it dries and shrivels; and if the part be very soft and of feeble vitality, it may produce a superficial eschar. The same preparations have been applied to *lupus eredens*, *tumors* of the female *urethra*, etc., and even to *cancer* of the breast (*Med. News*, xl. 401). They will not act upon parts covered with

cuticle or epithelium. The application causes severe pain, which may be palliated by morphia; its action does not tend to spread, and the eschar separates more rapidly than that of most other caustics. Sulphate of zinc may be used in weak solution to lessen the secretion in *eczema* and appease the itching in that and other cutaneous affections.

Internally, sulphate of zinc is given chiefly as an *emetic* to empty the stomach of indigestible or poisonous ingesta, especially such as are not themselves local irritants, and notably narcotic poisons, such as opium, strychnine, mushrooms, *rhus toxicodendron*, etc. As it is a mechanical and not a sedative emetic, it is greatly to be preferred before tartarized antimony in these cases, and also when the *air-passages* are obstructed by foreign bodies or by *false membrane*, as in *croup* and occasionally in *diphtheria*. It was claimed in 1879 by Fukala that he cured sixty-two out of seventy-two cases of *pseudo-membranous croup* by repeated applications of a 2½ per cent. solution of sulphate of zinc to the interior of the larynx by means of a syringe with a long curved pipe (*Bull. de thérap.*, xcvii. 143). Evidently, the statement is inadmissible. This medicine has been used alone or combined in *dysentery* and *typhoid fever*, but it is only in the chronic form of the first-named disease, and in greatly prolonged cases of the latter with predominant intestinal symptoms, that it is indicated. In *atonic dyspepsia*, with flatulent distension of the digestive canal, it is certainly of use, perhaps by its stimulant and astringent operation. It is reported to be efficacious in nervous *palpitation* of the heart, but probably in dyspeptic cases only. Possibly, a similar explanation may be applied to its alleged success in *spasmodic asthma*, but when this affection is associated with bronchorrhœa the efficiency of the medicine is more probable. In *whooping cough* it has enjoyed a certain reputation which may have been due to a similar mode of action—*i. e.* to its influence in eliminating the catarrhal element. Certainly, when associated with belladonna its usefulness is increased. The efficacy claimed for it in *chorea* is not sufficiently demonstrated. Very often it was associated with valerian, which of itself is at least as potent as the zinc. (Compare *Med. News*, xli. 261.) The latter is, however, as much to be depended upon as any other single medicine.

Administration.—As an emetic sulphate of zinc may be prescribed in *doses* of from 10 to 60 grains (Gm. 0.60–4) dissolved in tepid water. Internally, from 1 to 3 grains (Gm. 0.06–0.18) may be given several times a day, and gradually increased. In the treatment of *chorea* it has been so given until more than 20 grains a day were taken, and without injurious effects. It is best administered in pill and after meals, except when it is intended to act upon the stomach itself.

A solution of *sulphide of zinc* has been prepared by dissolving equal parts of sulphate of zinc and sulphuret of potassium in water. Such a solution, containing from 5 to 15 grains of each salt in an ounce of water, with the addition of a few drops of alcohol, is recommended by Dr. Duhring in the superficial inflammatory form of *lupus erythematosus*, and in *seborrhœa* of the face. The lotion should be shaken before being applied by means of a sponge or rag mop, and its sediment should be allowed to adhere to the surface. Its immediate effect is said to be soothing and cooling in the first-named disease, and its permanent influence more favorable than that of the numerous applications which are apt to be fruitlessly made in this affection (*Med. News*, xliii. 507).

ZINCI VALERIANAS, U. S., Br.—VALERIANATE OF ZINC.

Valerus zincicus, F. Cod.; *Zincum valerianicum*.—Valériante (Valérate) de zinc, Fr.; Zinkvalerianat, Baldriansaures Zinkoxyd, G.

Formula $\text{Zn}(\text{C}_5\text{H}_9\text{O}_2)_2 \cdot \text{H}_2\text{O}$. Molecular weight 284.9.

Preparation.—Take of Valerianate of Sodium 5 oz. av.; Sulphate of Zinc 5½ oz. av.; Distilled Water a sufficient quantity. Dissolve the salts separately, each in 2 pints (Imperial) of distilled water; raise both solutions to near the boiling-point, mix them, cool, and skim off the crystals which are produced. Evaporate the mother-water at a heat not exceeding 200° F. to 4 fluidounces, cool again, remove the crystals which have formed, and add them to those which have already been obtained. Drain the crystals on a paper filter, and wash them with a small quantity of cold distilled water till the washings give but a very feeble precipitate with chloride of barium. Let them now be again drained and dried on filtering-paper at ordinary temperatures.—Br.

The above process was originally proposed by Trommsdorff. On mixing hot solutions of valerianate of sodium and sulphate of zinc the salts are mutually decomposed, resulting in the formation of sulphate of sodium, which remains dissolved, and valerianate of

zinc, which crystallizes partly on cooling, the remainder being obtained on concentrating the liquid.

The salt of the French Codex is obtained by adding freshly-prepared moist carbonate of zinc to valerianic acid, diluted with 30 parts of water, and when the acid is nearly saturated warming the mixture slightly, filtering, and carefully evaporating the liquid.

Properties.—Valerianate of zinc crystallizes in soft white pearly scales, which are not deliquescent, and have a slight odor of valerianic acid and a sweet styptic and metallic taste. It has an acid reaction on litmus-paper, melts at about 140° C. (284° F.), at a higher heat gives off white inflammable vapors, and finally burns with a bluish flame, leaving oxide of zinc. The salt is stated to be soluble at 15° C. in 90 (*P. G.* 1872), 100 (*U. S.*), 160 (Wittstein) parts of water; the salt used in France, which contains $12\text{H}_2\text{O}$, dissolves in 50 parts of cold water (*F. Cod.*); on being boiled with water it loses water of crystallization. But, according to Lieben and Rossi (1871), 100 parts of water dissolve at 25° C. (77° F.) 2.54 parts of anhydrous valerianate of zinc. On heating the solution moderately it becomes turbid, and clear again on cooling; but after the saturated solution has been boiled it does not become entirely clear after cooling, in consequence of the production of a basic salt, which is less freely soluble in water. The salt is also soluble in 40 (*U. S.*), 60 (Wittstein) parts of cold alcohol, and this solution is likewise rendered turbid by heat. Hot ether, however, dissolves it more freely than cold ether. When kept over sulphuric acid the salt becomes anhydrous.

Tests.—Valerianate of zinc should be completely soluble in ammonia-water. Its aqueous solution yields a white precipitate with sulphuretted hydrogen, and when an excess of the reagent has been used the filtrate on being evaporated should leave no fixed residue. Acetate of zinc, being freely soluble in water, if present as an adulteration would impart a red color to solution of ferric chloride. Butyrate of zinc resembles the valerianate closely; it is detected, according to the British Pharmacopœia, by distilling the suspected salt with dilute sulphuric acid and adding the distillate to a solution of acetate of copper, when, if the valerianate be pure, it does not immediately affect the transparency of the fluid, but forms after a little time oily drops, which gradually pass into a bluish-white crystalline deposit. This is the test suggested by Larocque and Huraut, who first directed attention (1846) to the similar physical properties of the two salts. The U. S. P. has adopted Hager's test, using cold concentrated solutions of zinc valerianate and copper acetate. It also requires the salt to yield 28.3 (theory 28.4) per cent. of oxide; owing to its volatility, the salt requires to be decomposed by nitric acid before it is finally ignited.

Medical Action and Uses.—This compound was originally introduced as uniting in itself the peculiar virtues of its two elements in a multiple ratio. This illogical and unscientific judgment did not prevent it from being largely used in spite of its high price and excessively offensive smell. It is very doubtful whether valerianic acid possesses any medicinal virtues; those belonging to valerian seem to reside in its oil. For a time valerianate of zinc was lauded in *neuralgia*, both external and internal, in *nervous headache*, *nervous vertigo*, *whooping cough*, *infantile convulsions*, and a variety of nervous and hysterical affections, including *chorea*. It was even declared to be a remedy for *cholera*! The only real merit it possesses consists in its sometimes alleviating neuralgic pains and headache occurring in very excitable or hysterical persons. A case is recorded of its having cured *diabetes insipidus*, but as valerian alone is recognized as one of the best remedies for that disease, and as the patient was also taking opium, the influence of the zinc salt cannot be regarded as proved. A recent case, however, gives some color to this alleged virtue of the salt (*Lancet*, Oct. 1881, p. 662). The *dose* of this preparation is variously stated at from half a grain to several grains. Probably 1 grain (Gm. 0.06) should be the average dose. It may best be given in pill with mucilage or conserve of roses.

ZINCUM, U. S., Br.—ZINC.

Speltrum.—Zinc, Fr.; Zink, G.

Symbol Zn. Atomicity bivalent. Atomic weight 64.9.

Origin.—The metal zinc has been known in the isolated state only since about the beginning of the eighteenth century, when Stahl showed it to be obtainable from calamine; some of its compounds, however, have been long known. Brass was used in ancient times, but no other metal, besides copper, was supposed to exist therein. The oxide was likewise known at an early date, and, like the ore from which it was obtained, was called *cadmia*. White vitriol appears to have been prepared by Valentinus in the

fifteenth century, who was also acquainted with blende, in which Brandt (1735) showed the presence of zinc, and Glauber (1648) prepared "oleum lapidis calaminaris," and studied some of the properties of zinc chloride.

The metal is rather abundant, and exists most generally in combination either as silicate or carbonate, known as *calamine*, or as sulphide, known as *blende*. Zinc ores have been found in Pennsylvania and Missouri, in Great Britain, Belgium, and different parts of Germany, particularly in Silesia. They are frequently associated with lead and other metals.

CALAMINA PRÆPARATA, Br. (*Lapis calaminaris preparata*), is native zinc carbonate, calcined in a covered earthen crucible at a moderate temperature, powdered, and freed from gritty particles by elutriation. It is a pale pinkish-brown powder, almost entirely soluble with effervescence in acids. The mineral varies in color from whitish to reddish or greenish, and is sometimes crystalline, or more frequently amorphous.

Preparation.—On smelting lead and other ores containing zinc an impure oxide of zinc is condensed in the cooler portions of the furnace. By the long-continued roasting of blende or calamine oxide is likewise obtained. This is mixed with powdered charcoal, and the mixture heated nearly to whiteness in shallow iron retorts, when the zinc distils, and is collected in suitable condensers. The impure metal is purified by a descending distillation in crucibles furnished with an open tube reaching to the upper half of the crucible and passing through its bottom.

Properties.—Zinc is a bluish-white metal, having a lamellar or a granular structure. Its density varies between 6.9 and 7.2, rolled zinc being the heaviest. Ordinarily, it is rather brittle, but between 120° and 150° C. (248° and 302° F.) it is ductile, and may be rolled into sheets and converted into wire. Heated to 205° C. (401° F.), it becomes so brittle that it may be reduced to powder. It melts at about 415° C. (779° F.), and at near a white heat it boils and volatilizes, and in the presence of air burns with a bluish-green flame to oxide. Melted zinc on congealing expands in volume 0.2 per cent. (Nies and Winkelmann 1882), and afterward contracts considerably. On bending, zinc emits a slight cracking noise, weaker than that of tin. It has a bright metallic lustre, but on exposure becomes superficially tarnished. It is not much acted on by cold concentrated sulphuric acid, but on heating unites with it, evolving sulphurous acid gas. Diluted sulphuric and hydrochloric acids dissolve it readily, with the evolution of hydrogen.

Zinc is extensively used in the arts for roofing and other purposes; melted together with copper it forms *brass*. It is useful in protecting surfaces of iron and copper from oxidation; iron having its surface coated with zinc is known as *galvanized iron*.

The *salts of zinc* are usually colorless, soluble in water, have an acid reaction, and a disagreeable metallic taste, and by prolonged heating are mostly converted into oxide. Their aqueous solutions, acidulated with hydrochloric acid, are not precipitated by sulphuretted hydrogen, but they yield with ammonia and potassa white precipitates soluble in an excess of the alkali. White precipitates are also obtained with sulphide of ammonium, alkali carbonates, and ferrocyanide of potassium; ferricyanide of potassium yields an orange-red precipitate.

Pharmaceutical Uses.—*ZINCUM GRANULATUM*, Br. Granulated zinc is obtained by melting commercial zinc in an earthen crucible and pouring the liquid metal in a thin stream into cold water. The congealed zinc is drained and dried.

The following *chemical compounds* of zinc are officinal: *Zinci acetas*, *Zinci carbonas*, *Zinci chloridum*, *Zinci oxidum*, *Zinci sulphas*, *Zinci valerianas*, *U. S.*, Br.; *Zinci bromidum*, *Zinci iodidum*, *Zinci phosphidum*, *U. S.*

The following *pharmaceutical preparations* contain compounds of zinc: *Liquor zinci chloridi*, *Unguent. zinci oxidi*, *U. S.*, Br.

Unofficial Zinc Salts.—*ZINCI CYANIDUM*, *Cyanuretum zincicum*, *F. Cod.*, Cyanide of zinc, $\text{Zn}(\text{CN})_2$. It is obtained by precipitating a solution of acetate of zinc with hydrocyanic acid, whereby acetic acid is liberated, which retains a portion of the zinc cyanide in solution; the liquid should therefore be kept nearly neutral by the occasional cautious addition of an alkali. Cyanide of zinc is a white, inodorous, and tasteless powder, which is insoluble in water and alcohol, but dissolves in potassa, ammonia, and in dilute acids. When long kept it undergoes decomposition and acquires a sweetish and metallic taste.

ZINCI ET POTASSII CYANIDUM, K_2ZnCy_4 . On dissolving zinc cyanide in a solution of pure potassium cyanide a slightly alkaline liquid is obtained, which on evaporation yields colorless or white octahedrons of a sweet and metallic taste. Small quantities of acids precipitate from its solution cyanide of zinc.

ZINCI FERROCYANIDUM, Zincum ferrocyanatum, Ferrocyanide of zinc. It is prepared by precipitating a soluble zinc salt with ferrocyanide of potassium, and forms a white tasteless powder, which is insoluble in water, alcohol, and dilute acids, and evolves hydrocyanic acid on being heated with dilute sulphuric acid.

ZINCI LACTAS, Lactas zincicus, *F. Cod.*, Zincum lacticum, Lactate of zinc, $\text{Zn}(\text{C}_3\text{H}_5\text{O}_2)_2 \cdot 3\text{H}_2\text{O}$. It is prepared as described on page 71, or by dissolving carbonate of zinc in dilute lactic acid with the aid of heat. It crystallizes in short quadrangular crystals which have an acid reaction and an acidulous metallic taste. The salt is not fusible, requires about 58 parts of cold and 6 parts of boiling water for solution, and is nearly insoluble in alcohol. It yields 27.1 per cent. of oxide of zinc.

ZINCI SALICYLAS, Salicylate of zinc, $\text{Zn}(\text{C}_7\text{H}_5\text{O}_2)_2 \cdot 3\text{H}_2\text{O}$. Vigier (1878) prepares this salt by heating salicylic acid with distilled water, adding gradually oxide of zinc suspended in a little water, and, when the oxide is no longer dissolved, filtering the solution. The salt crystallizes in long satiny needles, has a sweet somewhat styptic and bitter taste, dissolves in about 20 parts of cold water, and is freely soluble in hot water, alcohol, ether, and methylic alcohol. The crystals represent 20.6, and the anhydrous salt 23.9, per cent. ZnO .

ZINCI SULPHOCARBOLAS, *Br.*, Zincum sulfocarbolicum (s. sulfophenylicum), *P. G.*, Sulphocarbonate of zinc, $\text{Zn}(\text{C}_6\text{H}_5\text{SO}_4)_2 \cdot 8\text{H}_2\text{O}$. It is prepared by dissolving 10 parts of crystallized carbolic acid in 12 parts of sulphuric acid, heating the mixture for several hours in a water-bath, neutralizing with carbonate of barium, filtering from the precipitated barium sulphate, and precipitating the filtrate accurately with sulphate of zinc; the precipitate of barium sulphate is filtered off, and the clear liquid evaporated to crystallization. Sulphocarbonate of zinc crystallizes in reddish, or if the solution has been acidulated with sulphuric acid in colorless, inodorous prisms or tablets, which are soluble in twice their weight of water or alcohol, have an acid reaction, and when heated are decomposed without melting. The aqueous solution acquires a violet color with ferric chloride, should yield with barium nitrate merely a slight turbidity (sulphate), should not be affected by ammonium oxalate or sulphuric acid (barium, etc.), and after precipitation with excess of ammonium sulphide yields a filtrate which on evaporation and ignition should leave no residue. When heated to redness the salt yields 14.6 per cent. ZnO .

Other sulphocarbonates may be prepared in an analogous manner by substituting for sulphate of zinc the carbonate or sulphate of the metal which is desired in the form of sulphocarbonate.

Medical Uses.—Zinc is never used as a medicine in the metallic state.

Cyanide of zinc, according to some early experimenters, occasioned, in doses of half a grain repeated at intervals, cephalic congestion, anxiety, somnolence, nervous tremors, etc. Given in large doses to animals, its effects are identical with those of hydrocyanic acid and its alkaline compounds. It has been used in *epilepsy*, *chorea*, and other convulsive affections, and also in *gastralgia* and other forms of *neuralgia*. In the last-named affection, and especially in neuralgia of the fifth pair produced by cold, its good effects appear to be proven. It may be prescribed in such cases in doses of about half a grain (Gm. 0.03) suspended in mucilage, or preferably in pill, to ensure its more precise administration. It should be given at intervals of an hour or two, since its physiological operation is transient. This salt has also been used with alleged benefit in acute articular *rheumatism*, but the evidence in its favor appears to be inconclusive.

A *cyanide of potassium and zinc*, which is permanent, and also perfectly soluble in cold water, has been proposed, and is to be preferred to cyanide of zinc on account of its solubility; it is prescribed in the doses already mentioned in sweetened aromatic water.

Lactate of zinc is reputed to be efficacious in the same affections for which the oxide is used, and to be less apt than the latter to disagree with the stomach. Its dose is stated to be from $\frac{1}{2}$ grain to 1 grain (Gm. 0.03–0.06) several times a day.

Salicylate of zinc is believed to be a valuable astringent and antiseptic agent. It has been applied to cancerous and other *ulcers*, and used for the treatment of *ophthalmia* and *gonorrhœa*, in a solution containing from $\frac{1}{2}$ to 1 per cent. of the salt.

Sulphocarbonate of zinc has been employed externally as a substitute for carbolic acid in surgical dressings, for the prevention of *septicæmia*, and as an injection in *gonorrhœa*, *leucorrhœa*, etc. It is less liable than carbolic acid itself to act as an irritant. A solution in water of the strength of from 1 to 5 per cent. is used as a topical application, and for injections a solution of from 1 to 5 parts in 1000.

ZINGIBER, U. S., Br.—GINGER.

Rhizoma zingiberis, P. G.—*Gingembre*, Fr.; *Ingwer*, G.

The rhizome of *Zingiber officinale*. *Roscoe*, s. *Amomum Zingiber*, *Linne*. Woodville, *Med. Bot.*, plate 11; Bentley and Trimen, *Med. Plants*, 270.

Nat. Ord.—Zingiberaceæ.

Origin.—The ginger-plant is a perennial herb indigenous to tropical Asia, and at the present time cultivated in most tropical countries, but it is not known in the wild state. It has numerous stems, about 40 inches (1 M.) high, and covered with elongated leaf-sheaths, of which the upper ones have a lance-linear spreading blade 8 to 12 inches (20–30 Cm.) long. The flowering stems are much shorter, have a few loose leaf-sheaths, and are terminated by a short thick spike of bracted yellow and variegated flowers. The rhizome is the part employed. 3,393,860 pounds of ginger were imported into the United States, in 1880, and 1,463,139 pounds in 1882.

Description.—Ginger is seen in commerce in two forms—either with the outer integuments present or else removed by scraping. The former kind is called *coated*, the latter kind *uncoated* or *scraped*, ginger; and this variety is recognized by the pharmacopœias. Commercial ginger consists of flattened branches of the horizontal rhizome, which are somewhat palmately lobed, are known in commerce as *races* or *hands*, and bear at the somewhat thickened end of each lobe a scar from the overground stem. The coated variety has simply been washed and dried, or slightly scraped upon the flattened sides; it is externally of a brown or yellowish-brown color, wrinkled, somewhat annulate from the leaf-bases, and has a more or less shrivelled appearance. The uncoated ginger is of handsomer appearance, of a pale-buff color, striated, and nearly smooth externally, or somewhat fibrous from detached fibro-vascular bundles; it breaks with a mealy and rather fibrous fracture, which is of a whitish or yellowish color. Well-dried coated ginger is slightly darker internally, but some varieties are quite dark-colored and break with a horny fracture. Coated ginger is often designated as *black ginger*, though this name is sometimes restricted to the horny kind, which appears to have been dried by artificial heat or after having been scalded in boiling water. Uncoated ginger is sometimes called *white ginger*; and this name is also used for certain varieties which have been artificially bleached, it is stated, by exposure to the fumes of burning sulphur, whereby they acquire

FIG. 308.

Coated Ginger.

FIG. 309.

Uncoated Ginger.

a chalky color, or by immersion in a mixture of chlorinated lime and water or in lime or gypsum. A transverse section shows near the surface a nucleus-sheath, and outside of this numerous small cells containing oil and resin; the central portion contains in the loose parenchyma many scattered small fibro-vascular bundles and a smaller number of oil-cells. The starch-granules of ginger are flat, vary in shape between narrow and broadly elliptical or ovate, have a small hilum near the narrow end, and are marked by numerous fine lines. They resemble the starch-granules of East India arrowroot, but are smaller (see page 197).

The variety of ginger preferred in the United States is known as *Jamaica ginger*, comes chiefly from Jamaica, and is distinguished by being longer and having more slender lobes than the African and East Indian ginger. Jamaica ginger affords a yellowish

powder; that of the other varieties is darker-colored. Ginger has a peculiar aromatic odor and a warm pungent taste.

Constituents.—The analysis of ginger by Bucholz (1817) proved the presence of volatile oil, a pungent soft resin, starch, and gummy and extractive matters. *Oil of ginger* is obtained to the amount of about $\frac{3}{4}$ to $1\frac{1}{2}$ or 2 per cent., has a pale-yellow color, the specific gravity 0.88 or 0.90, and has the peculiar odor of ginger, but rather a mild taste. According to Papoušek, it is a hydrate of $C_{10}H_{16}$. J. C. Thresh (1881) found the oil to boil between 150° and 300° C.

FIG. 310.

Ginger Starch-Granules.

FIG. 311.

Transverse section, magnified 3 diam.

(302° – 572° F.), and to contain hydrocarbons of the formula $C_{15}H_{24}$, cymene, a little formic and acetic acids, and various oxygenated compounds, without notable quantities of ethers and aldehyds. Thresh (1879–82) recognized in ginger the presence of traces of an alkaloid, and named the pungent principle *gingerol*. It is a straw-colored, viscid, odorless fluid, has an extremely pungent taste, is sparingly soluble in petroleum benzine, freely soluble in alcohol, diluted alcohol, benzol, volatile oils, carbon bisulphide, alkalies, and glacial acetic acid. It is not a glucoside, has an alkaline reaction, gives precipitates with lead, barium, and magnesium salts, slowly loses weight at 100° C., is decomposed by boiling water and alkali, and readily oxidized; its isolation is a matter of great difficulty. Jamaica ginger yields the smallest, and African ginger the largest, amount of volatile oil, resins, and gingerol, and the former variety yielded the largest percentage of mucilage, metarabin, starch, and albuminoids. Stenhouse and Groves (1877) obtained a little protocatechuic acid on melting the resinous extract with soda. Thresh ascertained that the greater portion of the resin is a neutral compound, and the remainder consists of two acid resins. The ash of air-dry ginger varies between 3.5 and 4.8 per cent., and the moisture between 13.4 and 14.5 per cent.

Off. Prep.—Acid. sulphur, aromat., Confectio opii, Conf. scammonii, Br.; Extract. zingiberis fluid., U. S.; Infus. sennae, Br.; Oleoresina zingiberis, U. S.; Pilulæ scillæ comp., Pulv. aromaticus (P. cinnamomi comp.), U. S., Br.; Pulv. jalapæ comp., Pulv. opii comp., Br.; Pulv. rhei comp., U. S., Br.; Pulv. scammonii comp., Syrup. rhamni, Br.; Syrup. zingiberis, Tinct. zingiberis, U. S., Br.; Tinct. zingiberis fortior, Br.; Vinum aloes, U. S., Br.

Other Products of Zingiberaceæ.—ZINGIBER (*Amomum*, *Linneé*) ZERUMBET, *Roscoe*. The zerumbet-root of Java is referred to this species. The rhizome is tuberous, somewhat flattened, spongy, internally yellowish, with pale-brown fibro-vascular bundles, and has an agreeable odor and a ginger-like somewhat bitter taste.

ZINGIBER CASSUMUNAR, *Rosburgh*. The cassumunar-root of India is probably obtained from this plant; it is about 2 inches (5 Cm.) in diameter, jointed, compressed, with numerous white fleshy radicles and some white tubers; it is externally scaly and light-brown, internally yellow and rather woody, and has a camphoraceous odor and a hot, aromatic taste.

GRANA PARADISI, Grains of paradise. Under this name the seeds of two plants are met with in commerce which resemble cardamom-seeds in size and appearance, but are destitute of the furrow seen on the latter. One variety is about $\frac{1}{2}$ inch (2 Mm.) in diameter, is irregularly roundish and angular, reddish-brown, somewhat glossy and finely warty on the surface, and has a rather broad and depressed hilum; it has been referred to *Amomum Granum-paradisi*, *Azelius*, a native of Sierra Leone. The other variety is obtained from *Amomum Melegueta*, *Roscoe*, which is likewise indigenous to Western Africa; the seeds are rather larger, $\frac{1}{10}$ or $\frac{1}{8}$ inch (2–3 Mm.) in length, and are distinguished from the preceding by the conical gray-brown tufted hilum; they are also known as *melegueta pepper* and *Guinea grains*. Both varieties are feebly aromatic and have a very pungent and burning taste. They yield about 0.3 per cent. of aromatic volatile oil, and contain acrid resin, starch, gum, etc. Grains of paradise are a constituent of some cattle powders, but are chiefly used for imparting artificial strength to liquors.

See also CARDAMOMUM, CURCUMA, GALANGA, and ZEDOARIA.

Medical History.—Ginger was introduced from Asia through Arabia into Greece and Europe generally, and the Arabian and later Greek physicians employed it as a condiment and carminative, and also as an aphrodisiac and general stimulant. They also recognized the effect of its excessive use in debilitating the stomach.

Medical Action and Uses.—Ginger is a carminative stimulant when taken internally, and when applied to the skin it occasions redness, heat, and tingling. Snuffed into the nostrils it is a powerful sternutatory, and when the rhizome is chewed it causes

a copious secretion of saliva. Ginger is largely employed in cooking, as the spices proper are, to render more digestible various preparations of flour, sugar, and certain vegetables, and also to expel the flatus produced by the decomposition of food in the digestive canal. In *flatulent colic* ginger is prescribed in powder or in tincture as a carminative and anodyne. It may be given in powder mixed with hot water, but the tincture is preferable. The infusion and tincture have been largely used to correct *diarrhoea* occasioned by cold, and even for a similar purpose in the forming stage of epidemic *cholera*. Ginger has also been recommended in *chronic bronchitis*.

As a rubefacient and anodyne it is much employed in cataplasms and fomentations for the relief of *colic*, *muscular rheumatism*, *neuralgia*, *toothache*, *headache*, etc. The infusion is of use in recent cases of relaxation of the *uvula*, and of *aphonia* from a similar condition of the larynx. The rhizome may be used as a masticatory in *paralysis* of the tongue, cheek, and parts supplied by the portio dura of the fifth pair.

The *dose* of powdered ginger is from 10 to 30 grains (Gm. 0.60–2.). The infusion, tincture, fluid extract, syrup, and oleoresin are officinal.

Grains of paradise are generally ranked with cardamom-seeds, but their acrid and exciting qualities are akin to those of ginger, for which they may in most cases be substituted.

ADDENDA.

ANTIPYRINA.—ANTIPYRINE.

Antipyrine, Fr.; *Antipyrin*, G.

Formula $C_{11}H_{12}N_2O$. Molecular weight 198.

Origin and Preparation.—The hypothetical compound N_2H_4 , which has been named *hydrazine* by E. Fischer, consists of the double molecule $H_2N.NH_2$ of amidogen. One or more of the hydrogen atoms may be replaced by hydrocarbons yielding volatile bases. By a complicated process *phenyl-hydrazine*, $C_6H_5N_2$ or $C_6H_5HN.NH_2$, is obtained; it is crystalline, melts at $23^\circ C.$ ($73.4^\circ F.$), and boils at $233^\circ C.$ ($451.4^\circ F.$). On treating this base with acetic ether at the temperature of the water-bath, L. Knorr (1883) obtained the crystalline compound $C_{10}H_{10}N_2O$, which has both basic and acid properties, and is the methyloxy derivative of *chinizine*, a hypothetical base having the composition $C_9H_{10}N_2$. For the preparation of antipyrine equal parts of methyloxy-chinizine, methyl iodide, and methyl alcohol are heated together in a sealed tube to $100^\circ C.$; the mass is then decolorized by boiling with sulphurous acid; the alcohol is distilled; and on the addition of concentrated soda solution the base is separated as a heavy oil and recrystallized from toluol or ether.

Properties.—Antipyrine crystallizes readily in laminae, or from water in rhombic prisms. The commercial article is a voluminous crystalline powder of a white or whitish color, having usually a grayish or reddish tint; it is almost inodorous, and has a mild bitter taste. At $15^\circ C.$ ($59^\circ F.$) it dissolves in about two-thirds its weight of water, in about one part of alcohol or chloroform, and in about 50 parts of ether, and is freely soluble in benzol, but slightly soluble in benzin. The aqueous solution yields precipitates with basic lead acetate, mercuric chloride, and most reagents for alkaloids, except potassio-mercuric iodide, and reduces Fehling's solution. 2 Cc. of a 1 per cent. solution acquire with 2 drops of fuming nitric acid a green color, changing to red on the addition of another drop of the acid to the previously boiled liquid. One drop of ferric chloride solution, added to 2 Cc. of a $\frac{1}{10}$ th per cent. solution of antipyrine, causes a deep-red color, changing to pale yellow on the addition of 10 drops of sulphuric acid. The solution of antipyrine in water should have a neutral reaction, should be colorless or faintly yellowish, should not have an acrid taste, and should not be affected by sulphuretted hydrogen. On the addition of nitrous acid or of nitroso-nitric acid to a cold concentrated aqueous solution of antipyrine, green crystals are separated. Antipyrine melts at $113^\circ C.$ ($235.4^\circ F.$), and when further heated turns red, then brown, and acquires an empyreumatic odor resembling oil of amber, the residue being soluble in alcohol and with a red color in chloroform. Antipyrine dissolved in wine causes the gradual precipitation of the coloring-matter from the latter. Syrup, or a fruit syrup with an aromatic spirit, has been found to be a suitable adjunct for the solution. The powder as well as the solution should be carefully protected from contact with iron compounds, and the solution should not be combined with spirit of nitrous ether.

Composition.—Antipyrine is dimethyloxy-chinizine, and has the formula $C_{11}H_{12}N_2O$. It is isomeric with methyl derivatives of tolylhydrazines, which, however, have an acid character. These compounds were discovered by Knorr (*Berichte d. Chem. Ges.*, 1884, pp. 546, 2032).

Physiological Action.—*On Animals:* Antipyrine exalts the reflex excitability of frogs, and ultimately excites tetanoid spasms; but when the spinal cord is divided these spasms cease below the point of section. They differ from those induced by strychnine. The affected animals may remain rigid for twenty-four hours, after which relaxation takes place, but anaesthesia continues twice as long. These effects seem to be represented by the conclusions of certain experimenters, who describe the agent as first stimulating and

then paralyzing the nervous centres. In frogs the pupils are always dilated, and the respiratory movements, quickened at first, become slower until they cease. In these animals the heart is generally unaffected, but sometimes is arrested in systole, according to (Appola; but Denme alleges that antipyrine destroys frogs and rabbits by paralyzing the heart, and that it is essentially a muscle-poison. Six grains administered in three successive hypodermic injections suffice to kill a rabbit of medium size. Beyer, however, found that it intensifies rather than diminishes the force of the cardiac contractions unless the dose be excessive (*Amer. Jour. Med. Sci.*, Apr., 1886, p. 401). *Non nobis est tantas componere lites*. Clinical experience proves that a dose which one person will readily tolerate may, under certain conditions, become dangerous to another person. Some experimenters assert that in rabbits and other warm-blooded animals tetanoid spasm and increased blood-pressure are primarily associated, but that afterward the pulse grows weak and irregular. Anseroff found that, although the external temperature might be greatly raised, there was a corresponding depression of the temperature of internal parts. This statement differs from that of Jaccoud, given below.

On Man: When antipyrine was first introduced little allusion was made to the vomiting it is apt to occasion. But afterward depression verging on collapse, with coldness, profuse sweating, irregular pulse, feeble voice, and vomiting, especially in females, were found to be ordinary consequences of what were then held to be efficient doses. To counteract them, cordial and nervine stimulants were administered. It often happened that the pulse and temperature did not fall in an equal ratio, and sometimes, indeed, the pulse-rate was increased instead of being slightly lowered, as it usually is. In healthy persons the temperature is but little if at all reduced by antipyrine; but in fever it begins to decline soon after the medicine is administered, and its subsidence is most marked within from four to six hours after the administration of 15 grains (Gm. 1), and by a repetition of the dose or the administration of a smaller one may be prevented from rising again. It appears that in children the sedative action on the pulse is insignificant. In all cases sweating is apt to be provoked by an excessive dose. Antipyrine is eliminated largely with the urine, but does not irritate the urinary tract. According to Jacobowitzsch, the quantity of urea, sodium chloride, and acids is notably diminished in children, and sometimes the urine itself is so to the extent of one-half. The experiments of Müller and the observations of Frankenberg (*Med. Record*, xxix, 585) and of Umbach (*Therap. Gaz.*, x, 621) go to show that under the influence of antipyrine a very large proportion of urea, that should be eliminated, is retained in the system. The addition to the urine of chloride of iron and the application of heat develop a dark-reddish color. Within ten minutes after the hypodermic injection of 6 grains of antipyrine it has been detected in the urine (Hage). The experiments undertaken to explain the action of this compound have been contradictory and insufficient in their results. Jaccoud, indeed, alleges that its lowering action upon the temperature does not extend to the internal organs. In many cases antipyrine produces an erythematous, measles eruption upon the trunk and limbs. It has been described as consisting of "irregularly rounded pimples lying close together and forming patches," and followed by a slight desquamation. It abounds most on the extensor surfaces, may present a few vesicles, and occasions itching. In some cases even bloody vesicles have occurred. The sedative action of antipyrine has occasioned death. A woman suffering from metrorrhagia (?) took 35 grains of it, and three hours later half of the like dose. She fell into collapse and died in thirty-two hours (*Lancet*, Feb. 28, 1885). Another case was reported by May of collapse which threatened death after the administration of 75 grains of the preparation (*Lancet*, 1885, p. 382). Strauss reports the occurrence of collapse in two instances during the second week of typhoid fever and after the administration of antipyrine in doses of 45 grains (*Therap. Gaz.*, ix, 862); and a third case occurred in the practice of the same physician (*Lancet*, Oct. 3, 1885). Welch describes another caused by only 10 grains (*Med. News*, xlviii, 9), and Graham one of a woman in the fourth week of typhoid fever who had taken five doses of 12 grains each at intervals of three hours. She fell into collapse, and was saved only by active stimulation (*Boston Med. and Surg. Jour.*, March, 1886, p. 261). In a report on the use of the preparation in the Boston Hospital, Dr. Mason states that 6 out of 100 patients suffered collapse after taking from 20 to 30 grains of it (*Boston Med. and Surg. Jour.*, Dec., 1885, p. 536). A case of sunstroke treated with antipyrine, given hypodermically, seems to have had a narrow escape from the lethal sedation of the medicine (*New York Med. Jour.*, July 25, 1885).

Medical Uses.—We have on many occasions protested against the use of merely

antithermic medicines in the treatment of fevers. The study of antipyrine offers an occasion for renewing the protest, and declaring that the reduction of temperature in healthy animals by poisons affords no warrant for employing such poisons in treating the fevers of human beings. The conditions in the two cases are neither identical nor analogous. All antithermic agents agree in demonstrating that behind its high temperature each febrile disease presents a specific element, be it a definite morbid poison, an alteration of the constitution of the blood, or some change in the solid tissues. The fever of phthisis, for instance, has a different nature from that of malarial fever, and the fevers of both these from that of an acute exanthem. To lower the temperature merely, even if it were possible at will to reduce it to the normal degree, is therefore a very different thing from removing the cause upon which the fever depends. But the cure involves the latter. Huchard, and after him Arduin, have insisted that a high temperature alone does not call for antipyretic interference, and that a temperature which is essentially normal in one disease is excessive in another, but only to such an extent as it exceeds the ordinary temperature in that disease. The worst mischiefs of antipyretics are due to a disregard of such laws and precepts. Antipyrine has been compared with other agents of the same class. Huchard has pointed out the following contrasts: Quinine is transient in its action; salicylic acid and its salts are uncertain, and if hæmorrhage already exists are apt to increase it; carbolic acid causes sweating, pulmonary congestion, and collapse; resorcin does not moderate hectic fever: it causes vertigo and auditory disorder, and but slightly modifies the temperature in typhoid fever; while kairine, although inducing a transient subsidence of fever, also occasions profuse sweat and chills, and, indeed, acts only after having brought about serious blood-lesions (*Bull. de thérap.*, cvii. 511). This is a succinct and emphatic condemnation of the antithermic agents enumerated, but it is nearly as applicable in degree, and quite as much so in kind, to antipyrine. If, too, kairine is to be rejected because it induces sweating, then antipyrine is quite as open to the same objection, for Frankenberg relates a case in which the loss of weight in this way amounted to a pound and a quarter in two hours; and yet it is in the hectic fever of phthisis that antipyrine is emphatically recommended, even while the advice is given that its tendency to promote sweating should be combated with atropine or agaricine!

Typhoid fever has been extensively treated by means of antipyrine. According to the most trustworthy reports, it moderates delirium and dryness of tongue in proportion as it reduces the temperature, whether the pulse-rate fall or not. But it does not shorten the course or lessen the mortality of the disease. The sole indication for its use in this as in other febrile diseases is hyperpyrexia, and hence the necessity for it cannot be very frequent. It has been noted that in this as in other febrile affections the urea diminishes and the sulphates increase in the urine under its use; and for this reason some leading clinicians reject antipyrine absolutely. In *intermittent fever* antipyrine is valueless, notwithstanding the plausible reasons assigned for its efficacy. It has been used with alleged advantage in the treatment of *puerperal metro-peritonitis*, but the cases published to illustrate its virtues do not appear to sustain the claim. In *pneumonia* it seems to have been less injurious than its action upon the heart would lead one to apprehend. It reduces the pulse-rate and temperature, and has been thought sometimes to bring about a critical sweat. But on the duration and mortality of pneumonia it exerts no favorable influence. Indeed, Posadski, who treated two series of cases, the one with antipyrine and the other with calomel, concluded that the latter was the superior remedy, in that it was followed by an earlier recovery. Moreover, of the 25 patients treated with antipyrine, no less than 5 suffered collapse, and 4 vomiting; 2 presented the specific eruption; and 11 the characteristic dark-red urine. These patients lost weight more than those of the parallel series, and their convalescence was slower (*Centralblatt f. d. g. Therapie*, iv. 215). Its virtues in the hectic fever of *phthisis* have been highly lauded; but experience has shown that only moderate doses of it should be used, such as 5 to 10 grains (Grm. 0.25–0.50) every hour or two. Sometimes, when the proper dose has been learned, the medicine renders more tolerable the sweats that beset the *consumptive* in the advanced stages of his disease. Beyond this it has no influence. In some cases of acute articular *rheumatism* antipyrine has appeared to reduce the pain and swelling in the joints. Neumann inclined to admit it almost to an equality with salicylic acid and the salicylates (*Centralblatt f. d. g. Med.*, iii. 542), and even claimed efficiency for it in the treatment of chronic rheumatism and rheumatic neuralgia. But Bamberger, whose authority is very high, expressly excludes antipyrine from the treatment of rheumatism and typhoid fever (*Therapeut. Gaz.*, x. 277), and to that judgment we adhere. In *diphtheria* the natural tendency of the disease to occasion syncope is increased by antipyrine.

Demme reports the case of a boy in which its administration was followed by fluttering of the heart, dilated and fixed pupils, and spasms of the limbs. Some recorded cases seem to indicate that antipyrine may be found useful in sunstroke or "thermic fever," but not in heat-exhaustion. But it should be used cautiously, and by the hypodermic method. Huchard ascribes *hæmostatic* virtues to antipyrine, which are also claimed for its internal as well as its topical use by Casati, who employed 5- and 6-per-cent. solutions. The judgment of the latter, that it is superior to ergot and the persalts of iron, is probably premature.

The estimate we have expressed of the medicinal value of antipyrine receives stronger confirmation the longer the medicine is submitted to clinical tests. One of the largest and latest contributions to our knowledge of the subject is furnished by Reihlen (*Deutsches Archiv für klinische Medizin*, April, 1886); and his inevitable conclusion is that, except in reducing febrile temperature, it exerts no favorable influence on any disease. This is in exact accord with what we have maintained.

Administration.—Filehne proposed that from 75 to 90 grains (Gm. 5–6) be given daily in divided doses, but others have advised only 7 or 8 grains (Gm. 0.50) as the whole daily dose. These methods had reference especially to the treatment of hectic fever, and the smaller quantities have been generally preferred. Demme recommended for infants under a year old 3 grains (Gm. 0.15) as a single dose, but for adults 30 grains (Gm. 2). It must be cautiously used for children. On the whole, it is prudent in every case to begin with a minimum dose and gradually increase it, or administer the same dose at longer intervals. Antipyrine may be given in an aromatic water or in a wafer. By the rectum it is claimed that 60 grains (Gm. 4) produce a more permanent effect than three times that quantity by the mouth (*Med. Record*, xxix. 254); but the more common opinion is that the results are nearly equal whether the medicine be given by the mouth or by the rectum. Suppositories have been used containing from 8 to 15 gr. (Gm. 0.50–1.) and 30 gr. (Gm. 2) of cacao-butter. They are recommended in bleeding piles. The medicine has also been given hypodermically, and it is said not to excite inflammation if used in a solution made with equal parts by weight of hot water and antipyrine. By this method doses only one-third as large as those given by the mouth are required, and their effects are more speedily produced.

COCAINÆ HYDROCHLORAS, *Br.*—HYDROCHLORATE OF COCAINE.

Cocainum hydrochloricum.—*Chlorhydrate de cocaïne*, Fr.; *Cocainhydrochlorat*, G.

Formula $C_{17}H_{21}NO_4HCl$. Molecular weight 339.4.

Preparation.—The outline of Lossen's process for the preparation of the alkaloid has been given on page 590. Niemann's process consists in preparing a tincture with alcohol acidulated with sulphuric acid, treating this with milk of lime to remove wax and coloring-matter, neutralizing the filtrate with sulphuric acid, distilling off the alcohol, diluting the residue with water, filtering, adding sodium carbonate, and agitating with ether. The impure alkaloid left on evaporation of the ether is again treated with acidulated water, sodium carbonate, and ether, then decolorized, neutralized with hydrochloric acid, and recrystallized.

Properties.—The salt crystallizes from water in delicate radiating groups of needles, and from alcohol in short and thin prisms. It usually is seen as a white crystalline powder, which is nearly inodorous, has a slight acid reaction and a bitter taste, produces on the tongue a tingling sensation followed by numbness, and is readily soluble in water, alcohol, and glycerin, but insoluble in ether and fixed oils. Cold mineral acids dissolve the salt without color. The aqueous solution yields yellow or light-yellow precipitates with gold chloride, platinum chloride, and picric acid, and white precipitates with mercuric chloride, stannous chloride, tannin, and with the alkalies and alkali carbonates, the latter precipitates being soluble in ammonia and ammonium carbonate. Giesel (1886) observed that the solution of the salt in water, if not too dilute, gives with solution of potassium permanganate a violet-purple crystalline precipitate of cocaine permanganate. A 2-per-cent. solution of the salt should not become brown on the addition of a drop of decinormal solution of potassium permanganate (absence of coloring and other organic matter, Lyons, 1886), and should yield no turbidity with barium chloride (sulphuric acid) or ammonium oxalate (calcium salt). Heated on platinum foil, the salt burns without leaving any residue.

Allied Salt.—COCAINE BENZOATE may be obtained by combining 2 parts of benzoic acid and 5 parts of cocaine with water and crystallizing at a low temperature. A solution of the salt may

be readily prepared from the acid and alkaloid in the proportion given. The salt crystallizes with difficulty in needles, and is very freely soluble in water; its solution yields with ammonia a precipitate of cocaine, and with hydrochloric acid a precipitate of benzoic acid. These reagents do not affect a solution of *benzoyl-cocaine*, which Paul (1886) observed has been sold in the place of the benzoate; it crystallizes more readily than the latter, is less freely soluble in cold water, and is formed from cocaine by the influence of water and heat, more particularly under increased pressure.

History.—It is claimed by Dr. Samuel R. Percy of New York that in 1857 he extracted from coca an alkaloid which he called erythroxylin, and which, as a muriate, had “a peculiar but not unpleasant benumbing and paralyzing effect upon the tongue, unlike that produced by aconitia, and not so persistent” (*Med. Record*, xxvi. 550). Toretti, a chemist of Bolivia, claims that Pizzi isolated the alkaloid of coca in 1857 (*Med. News*, xlix. 111). In 1862, Schroff accurately described its action. Between that date and 1865 sulphate of cocaine was used in the treatment of intermittent fever (Guibert), and in 1868, Gubler stated the dose of the muriate of cocaine to be from 7 to 30 grains (Gm. 0.50–2) (*Commentaires thérap.*). In 1879, Kobert found that it acted on striated muscle in the same manner as lead and emetine; and even as late as 1885, Brunton wrote, “Emetine and cocaine have a similar action to lead”! Meanwhile, Buchheim in 1883 described it as a feeble narcotic with a tendency to produce vomiting, colic, and diarrhoea! Although the local anæsthetic action of the salt was unnoticed by all of these experimenters except the first named, it was observed by Frommüller in 1863, by Gazeaux in 1870, and by Fauvel in 1879. By Gazeaux it was employed to relieve some painful affections of the mouth and stomach. But these important observations attracted little attention, as well as those of Moreno y Maiz, who in 1868 asserted that the new alkaloid destroyed sensibility, but not motility, and that it dilated the pupil—a statement confirmed by Ott in 1874. In 1877, Saglia showed that tincture of coca obtunded the sensibility of the pharynx; and in 1882, Gougenheim stated that a watery solution of the extract produced a like effect upon the larynx. In 1880, Von Anrep’s experimental investigations confirmed and enlarged previous results, and drew attention to the local anæsthetic action of the preparation. These various demonstrations, however, failed to attract general attention, and it was not until the anæsthetic virtues of cocaine in operations on the eye were exhibited by Koller at Vienna in October, 1884, that this precious discovery was accepted and generally employed in America and Europe. The observations of Koller, and those of Koenigstein made at the same time, entirely coincided.

Physiological Action.—*On Animals:* Frogs are said to be much more sensitive to the action of cocaine than warm-blooded animals, and are rendered anæsthetic by cocaine applied to the skin. According to some experimenters, it also impairs reflex activity. In doses of gr. $\frac{1}{10}$ to gr. $\frac{1}{40}$ (Gm. 0.0005–0.015) it stimulates and then paralyzes the organs of volition and respiration and dilates the pupils; larger doses occasion reflex spasm and anæsthesia; and excessive or lethal doses immediately produce muscular resolution. In warm-blooded animals the effects are essentially the same, and death is said to be directly due to an arrest of respiration. The breathing becomes hurried at first in these animals, but in the cold-blooded it is at once suspended. In both species respiration ceases before the heart. In large doses it produces an unsteady gait and general inco-ordination which may end in convulsions. Like many other stimulants, it excites and then depresses the great functions. Applied in a watery 2-per-cent. solution to the eye, it causes complete anæsthesia of the cornea and conjunctiva, which lasts ten minutes on an average. The iris retains its sensibility. Koenigstein is said to have enucleated the eye of a dog after injecting the orbit with a solution of cocaine without the animal’s being secured or appearing to suffer (*Kobert’s Jahresbericht*, 1885, p. 204). He also showed by an ophthalmoscopic examination that the red vascular network of the interior of the eye of a white rabbit became pale under the action of the medicine. In this connection it is to be noted that Beyer found in terrapins that the heart was stimulated and the blood-vessels contracted by cocaine (*Amer. Jour. of Med. Sci.*, July, 1885, p. 60). Experiments by Würdinger prove that a 5-per-cent. solution applied to a rabbit’s eye, with continued exposure to the light, will produce an erosion of the cornea followed by opacity of this tissue—an effect ascribed to the action of cocaine in contracting the blood- and lymph-vessels of the part (*Centralbl. f. d. g. Therap.*, iv. 321). These results bear upon the alleged tendency of panophthalmitis to occur after operations on the eye in which cocaine is used.

On Man: Like many other nervines, cocaine in sufficient dose first excites and then

benumbs general sensibility—an effect exhibited by the mouth and throat when the medicine has been applied in a liquid form. If water is taken immediately afterward, it produces an impression of coldness upon these parts, such as is felt after they have been touched with oil of peppermint. General numbness is not observed unless the dose is large, and does not usually follow the primary stimulation as rapidly as in the case of opium or alcohol. The action of cocaine upon the nervous system was first described by Schroff as resembling that of Indian hemp. It occasioned indistinctness or confusion of thought and of the senses, a glow throughout the body, and at first a general sense of cheerfulness and well-being, but later on giddiness, disorder of the senses, buzzing in the ears, dilatation of the pupils with impaired accommodation of the eye, paleness of the conjunctivæ, headache, restlessness, a sense of walking upon air, quickened and then retarded movements of the chest and heart, eructations, occasional vomiting, and sometimes sleep. This comparatively cheerful intoxication produced by moderate doses was associated with a singular endurance of fatigue and insensibility to hunger. These effects of an internal dose of about 2 grains of the substance may last four or five hours, during which time, says Frend, the muscular power is notably increased (*Lancet*, April 4, 1885).

Dr. DaCosta in 1884 found that, whether the hypodermic injection of cocaine rendered the pulse faster or slower, it always increased its fulness and strength, and also that the urine appeared to be increased in quantity, while its specific gravity was decidedly lowered and the phosphates in it were increased (*Trans. Coll. Phys. Philada.*, 3d Ser. viii. 39). In 1886, Drs. DaCosta and C. B. Penrose reported that in eight cases in which cocaine was administered from one to three times daily, by the mouth or hypodermically, and in doses of $\frac{1}{2}$ to 1 grain, there was a marked increase in the amount of urine voided in seven, and that without any marked change in its specific gravity. These observers were disposed to attribute the diuretic action of the medicine to its raising the arterial tension, and to believe that this action persists for some time after the cocaine has ceased to be administered (*Ibid.*, xlviii. 677). Confirmation of these results is furnished by the experiments on men and dogs made by Bignon of Lima, who, however, found that the diuresis produced by cocaine is not the result of the primary action of the drug. On the contrary, he claimed that cocaine tends primarily to diminish, and in large enough dose to suppress, the urine and induce uræmic phenomena with a fatal tendency, but that in duly-apportioned doses it excites diuresis without cerebral symptoms (*Bull. de thérap.*, cxi. 121). It is to be remarked, however, that in none of the cases cited below to illustrate the action of cocaine is any mention made of its causing either diuresis or suppression of urine.

The effects of an inordinate dose taken internally were exhibited in the case of a man who is stated by Ploss to have swallowed a glass of beer containing 20 grains of cocaine. The first effect was a peaceful sleep of several hours, followed by thirst and a burning sensation and dryness in the mouth. Vomiting ensued, with retention of urine. It is said that neither heart nor mind was disturbed (Husemann and Hilger, *Die Pflanzenstoffe*, p. 882). Before an operation for stricture of the lachrymal duct a 4-per-cent. solution was applied over the lower punctum, and at the end of twenty minutes the patient complained of dryness of the tongue and dizziness, and the pupil was widely dilated (*Med. Record*, xxvii. 265). It is stated that no local anæsthesia was produced in this case, which suggests that the solution employed may have been one of atropine. A lady who had several drops of a cocaine solution instilled into the nostrils suffered chilliness, excitement followed by depression of spirits, staring eyes, nausea, wakefulness, difficulty of thinking and speaking, and her gait was tottering. She had a loathing for food (Bresgen, *Times and Gazette*, Nov., 1885, p. 709). A boy with laryngeal papilloma had a solution of cocaine liberally applied to the part. For five hours he lay in a sleepy condition, but with open eyes, whose pupils reacted normally. These symptoms lasted for ten hours, when they were followed by sleep (*Times and Gaz.*, Nov., 1885, p. 741). Ziem collected fourteen cases which occurred under similar conditions and with like results (*British Med. Jour.*, Nov. 21, 1885).

According to Grove, a solution which after a fortnight presents a fungoid growth within it does not lose its mydriatic power, although its anæsthetic virtue is impaired; and also a 1-per-cent. solution acts as a mydriatic as energetically as a 4-per-cent. solution, although the influence of the latter is more prolonged. By the same observer it is stated that blue eyes are more promptly affected than black. Meyer and Bardet, on the other hand, declare that a 10-per-cent. solution acts both more promptly and more energetically than a feebler one (*Bull. de thérap.*, cviii. 122). Dr. Warfield and Mr. Donald-

son determined that in the eye and the mouth rendered anæsthetic by cocaine the perception of heat and cold is not lost (*Med. News*, xlv. 623). The skin around the point of hypodermic injection becomes pale as well as anæsthetic within an area of from half an inch to an inch in diameter. Dr. Hepburn estimates this diameter at sixteen lines when 6 minims of a 2-per-cent. solution are injected (*Med. Record*, xxvi. 534). He made several self-injections in adjacent spots, and within half an hour found his pulse and respiration quickened, experienced an agreeable sense of warmth, some disorder of vision, and, when his eyes were closed, pleasant hallucinations. On one occasion he used sixteen injections of 8 minims each, and suffered a general impairment of cutaneous sensibility, with a tendency to walk on the heels, and, on grasping an object, a sensation as if something spongy were interposed. Another physician describes the effects of two subcutaneous injections, each of half a grain of muriate of cocaine and repeated within five minutes, as consisting only of slight dizziness, pricking of the fingers, and a sense of epigastric pressure. Later on, he employed 2 grains at once. Within two minutes his heart beat violently, the blood seemed rushing into his head, and roaring noises filled his ears. The mind and will were impaired. The fingers and toes twitched and were numb, and there was nausea with gastric oppression. The face was pale and covered with cold perspiration; the pupils were enlarged, and vision was slightly clouded; the pulse was feeble, and the heart's force somewhat reduced (*Jour. Amer. Med. Assoc.*, vi. 278).

Knapp and others early noted that the injection of a 3- or 4-per-cent. solution, especially into the loose tissue of the orbit, may be followed by pallor and faintness (*Med. Record*, xxvi. 662). A man had injected under the conjunctiva 4 minims of a 3½-per-cent. solution of cocaine muriate, and within eight minutes was seized with convulsions followed by maniacal frenzy (*Ibid.*). Possibly the patient was an epileptic. The injection of 5ss of a 2-per-cent., and immediately afterward of a 4-per-cent. solution into the urethra occasioned a tendency to collapse (*Med. News*, xlv. 138); and one-third of a grain hypodermically produced similar effects, with the addition that "the pulse remained slow and feeble for some time afterward" (*Bull. de thérap.*, cviii. 122). Dujardin-Beaumetz relates that a morphine habitué under cocaine influence fancied himself a balloon for the space of twenty minutes. It would seem that the habit either of opiate or of alcoholic intemperance renders the action of cocaine less energetic. A consumer of morphine substituted cocaine for that drug, using it hypodermically. He increased the dose until it reached to from 5 to 7 drachms of a 4-per-cent. solution. The symptoms produced resembled those of delirium tremens (Merriman, *Jour. Amer. Med. Assoc.*, v. 430). Bauer reports the case of a drunkard who could take 10 grains of cocaine in a single hypodermic injection. Its direct action, which did not extend beyond two hours, presented nothing remarkable; but ultimately the pulse-rate was increased, the appetite impaired, emaciation set in, and constipation was established (*Med. Record*, xxviii. 603). A man gradually formed the habit of taking daily 12 grains of cocaine. He grew very weak, his pulse-rate was 100, and his mind was disordered as in delirium tremens (*Med. Record*, xxviii. 604). Medical Inspector Spear, U. S. N., has reported the case of an intemperate marine who took hypodermically 10 grains of muriate of cocaine within eighteen hours. About two hours after the last injection his face was ashy pale, his lips and hands blue, and his skin bathed in perspiration. The pulse was feeble and fluttering, his breathing slow and almost imperceptible, and the pupils contracted. The man recovered (*Med. Record*, xxviii. 36). Except in the state of the pupils this case is paralleled by that of a woman who snuffed 3 grains of powdered cocaine. She grew dizzy, weak, and faint, her sight was darkened, and semicoma followed, with a rapid pulse and dry hot skin. Yet she complained of cold and her teeth chattered, and her pupils were dilated. Recovery was promoted by brandy and ammonia (*Ibid.*, p. 604). The pupils were contracted in the case of a man into the sole of whose foot had been injected 10 drops of a 4-per-cent. solution. In four minutes alarming syncope occurred, the pulse was only 48, and the respiration from seven to eight a minute (*Ibid.*, p. 632).

Disorder of the nervous system was conspicuous in two cases reported by Dr. Brown (*Jour. Amer. Med. Assoc.*, vi. 61). A physician aged 30 began the use of cocaine as a remedy for hay fever, and at last took 5 grains at a dose in the morning. It excited him so much that he worked at his desk nearly all night, but on the succeeding day he had neither appetite for food nor any energy of body or mind. Gradually came on irregularity of the heart, emaciation, debility, dyspepsia, and pale stools. In the other case a physician substituted cocaine for opium, to the use of which he was addicted, and at last employed daily 15 grains of it hypodermically. He grew irritable, quarrelsome, and insisted that cocaine was a medical panacea. He became arrogant and overbearing,

and brandished a pistol in public places, meanwhile neglecting all his duties and deteriorating mentally as well as physically. Finally, he was placed in an asylum, from which he eloped and disappeared. Obersteiner enumerates among the evils attributable to cocaine a persistent wakefulness that sometimes sets in a few hours after the medicine is used; sexual excitement, which is, however, seldom observed; and, at a later period, vivid hallucinations (*Centralblatt f. d. ges. Therap.*, iii. 496). The only case we have found recorded in which death seemed to have been at all the consequence of poisoning with cocaine is that of an insane woman with a suicidal tendency, who, however, appears to have been affected with disease of the brain (*Jour. Amer. Med. Assoc.*, vi. 166). A case reported by Schilling (*Centralblatt f. d. ges. Therap.*, iv. 88) is of special interest. A woman seven months pregnant, requiring the extraction of a tooth, had 2 drops of a 20-per-cent. solution injected into the gum. The usual toxic symptoms ensued, but persisted so long as to become alarming, when they were entirely dissipated by the inhalation of *amyl nitrite*.

The first trials with cocaine upon the eye, by Shakespeare, showed him that 2 drops of a 2-per-cent. solution instilled between the lids caused no pain, and rendered the conjunctiva insensitive to pain within five minutes, although the sense of contact and of temperature remained unimpaired. Ten minutes later the pupil expanded to nearly twice its original diameter, and the vision became slightly indistinct. Twenty-five minutes afterward the pupil was only a little larger than that of the opposite eye. At the end of four hours the pupil and the power of accommodation had become normal (*Med. News*, xlv. 508). Koller, in his original paper on this subject, says, however, that the senses of pain, contact, and temperature are abolished, as well as the reflex excitability; and such is the accepted belief. Koenigstein, and also Koller, observed that the cocaineized eye protrudes more than the other, that the palpebral opening seems larger, and that the conjunctival blood-vessels contract so much as to render the surface pale. The last-named effect occurs in all vascular tissues to a greater or less degree. The conclusions of Zierninski from a large number of observations are practically important. From 3–6 drops of an 8–10-per-cent. solution of cocaine muriate can, in about five minutes on an average, produce anaesthesia of the cornea and conjunctiva sufficient for any operation on the eye, and lasting from nine to twelve minutes. Renewed applications will prolong the anaesthesia indefinitely. It is claimed that such uses of the agent neither irritate the eye nor affect the general system (*Jahresbericht d. Pharmakotherapie*, 1884, p. 206). This statement is no longer quite accurate. Many instances have been published of toxic phenomena following the use of cocaine in operations on the eye. Five such cases are reported by Bellyarminoff. The symptoms comprised headache, vertigo, nausea, vomiting, delay in the healing of the corneal wound, and sometimes keratitis (*Lancet*, Nov. 7, 1885). Again, Meyerhausen mentions the case of a girl who had the cornea scraped while at intervals about 15 drops of a 2-per-cent. solution of cocaine were instilled into the eye. She complained of headache, irritation of the throat, nausea, and anorexia; she was languid and feeble, staggered in walking, and her speech was thick. These symptoms continued for nearly a day (*Centralblatt f. d. ges. Therap.*, iii. 457). Schwarzbach relates that a woman affected with trichiasis applied a solution of cocaine to the eye to relieve pain. She suddenly fell into a collapse, from which wine and strong coffee rescued her (*Phil. Med. Times*, xvi. 787).

The question has been asked, How can coca be a nervous stimulant when its alkaloid, cocaine, is a nervous sedative? It is merely a question of dose. All stimulants of the nervous system become sedatives of it when employed in excessive doses—*e. g.* heat, cold, alcohol, opium, ether, chloroform, etc. An internal dose proportioned to that which occasions anaesthesia in the space of a square inch would directly arrest the essential functions of life.

Surgical Uses.—The sole purpose of cocaine is to prevent or relieve pain by its local anodyne or anaesthetic action. It is evident that the number of cases in which these indications may exist is almost endless. We shall enumerate the most important of them. First in point of time, and perhaps in relation to the usefulness of the medicine, are *diseases of the eye* requiring operations. As already stated, it was in them that it was first practically made useful by Koller in 1884, and in October of that year employed in New York by Agnew, Moore, Roosa, Knapp, and Mittendorf in various minor ophthalmic operations, including *strabismus*, and shortly afterward in *cataract*, *iridectomy*, and *wounds* of the eye. Within a week or two it had been tested in the same way by ophthalmologists in Boston and Philadelphia and other cities, and all agreed that henceforth neither chloroform nor ether need be used in operations upon the eye, and

that, consequently, the safety of patients and the convenience both of patients and surgeons were greatly promoted by the new discovery. The use of this agent in operations for cataract has, however, been charged with certain untoward effects by several oculists, including ulceration and exfoliation, or opacity, of the cornea, tardy healing of the wound made in operating, and even destructive inflammation of the globe. But it is denied, on the other hand, that such results are attributable to cocaine when a fresh solution of it is employed, and certainly they are not more frequent than such as attend the use of general anæsthetics. Indeed, it is claimed that it obviates most of the risks which they involve. Among the other operations in which this agent has been found valuable are the following: *incision of the lachrymal ducts, growths on the conjunctiva and cornea*, and all operations on the *interior of the eye*, including *paracentesis, iridectomy, prolapse of the iris, enucleation, and evacuation of the eyeball*. In the two operations last mentioned it is necessary to inject the solution behind the globe. The operations for *staphyloma, pterygium, tenotomy, removing foreign bodies, cautery, and trachoma* have been greatly facilitated by its use. It has been suggested that its association with atropine, so as to obtain a maximum dilatation along with the greatest hyperæsthesia, is to be preferred in iritis, and is indicated in operating for cataract by extraction (atropine $\frac{1}{5000}$ and cocaine $\frac{1}{200}$ in solution or in gelatin disks). If the dilating action is excessive, it can be corrected by eserine. This agent has also been used to combat the injurious effects of cocaine in *glaucoma*, as it had already been for a similar purpose where atropine was employed to dilate the pupil. But the dominant opinion is that cocaine is not adapted to the operation for *glaucoma*. Indeed, there is also laid to its charge that it tends to cause opacity of the cornea after operations for cataract; and this effect is explained by its constricting action upon the blood-vessels: it has certainly seemed to occasion exfoliation of the corneal epithelium. Objection has also been made to introducing it into the anterior chamber of the eye to blunt the sensibility of the iris: it is charged with having in this way caused panophthalmitis. Cocaine is incomparably the best application for relieving *photophobia* in cases of ulcer of the cornea or conjunctiva, and for facilitating *ophthalmoscopic examinations*. An East Indian surgeon states that a 2-per-cent. solution reduced greatly the size of *hypopion*. In a word, the most important indication for the use of cocaine is the spontaneous existence or the mechanical production of pain. It is thought by some that the *oleate* is superior to the muriate of cocaine, especially in ophthalmic surgery, on the ground that it is a more powerful anæsthetic, that it causes more prolonged mydriasis, and that it is less liable to be washed away by the tears (*Med. Record*, xxvii. 264).

Cocaine is of singular utility in affections of the *nasal cavity*, owing not only to its anæsthetic virtues, but also to its power of contracting or constricting the Schneiderian membrane and thereby enlarging the nostrils. In ordinary *coryza*, whether acute or chronic, this action is of marked advantage. A roll of fine and soft cambric saturated with a 5-10-per-cent. solution of cocaine muriate has been introduced into the nostril, but the mechanical irritation thus produced is very objectionable. Absorbent cotton is preferable to any woven tissue for this purpose. Cocaine mixed with an inert powder and used as a snuff has also been employed, especially in *hay fever*, but it also is irritating to the inflamed membrane. Dr. DaCosta has recognized the truth that in this disease cocaine is rather a palliative than a cure, but, still, a very valuable remedy. He recommends that from 5 to 8 drops of a 4-per-cent. solution should be injected into each nostril with a syringe while the head is thrown backward and care is taken not to irritate the nasal membrane with the instrument (*Trans. Coll. of Phys. Philadelphia*, 3d Ser. viii. 197). Some persons have advised that the solution be applied to the eyes and allowed to reach the nostrils through the lachrymal ducts. But this is an indirect and unpractical method. The constricting and anæsthetic action of the preparation facilitates all *operations* within the nose, such as the removal of *polypi* and other *tumors*, the reduction of *hypertrophy* of the lining membrane, the overcoming of nasal *stenosis*, the use of *caustics*, etc. It is also valuable as a means of arresting *epistaxis*.

The application of cocaine to the *pharynx* has been of great value in facilitating the use of *instruments* employed in treating affections of this region and of the larynx, including the use of the *rhinoscope* and the *laryngoscope*, and also the introduction of the *stomach-tube*. In removing tumors of the larynx the previous great difficulties of the operation have in a great measure been overcome by its use. It has also rendered more tolerable the difficulties of *deglutition* which occur in certain cases of pulmonary *tuberculosis*, *syphilis*, *cancer*, etc. Strong solutions are here to be preferred, such as from 4 to 6 per cent., but some German operators have used even 20-per-cent solutions. It has been

claimed that a 4-per-cent. solution will dissolve the false membranes of *diphtheria* (*Med. News*, xlv. 455; *Therapeutic Gaz.*, ix. 657). *Tonsillotomy* is said to be painless after the enlarged gland is well painted with a 3-per-cent. solution. The operation for *cleft palate* is greatly facilitated by it. In *hydrophobia* it is alleged to have enabled the patients to swallow liquids (*Therap. Gazette*, ix. 395). Before the introduction of cocaine infusions of coca were used as gargles, and also as atomized liquids, in various affections of the air-passages and throat, and particularly in the treatment of *whooping cough*; the alkaloid and its preparations have been applied to the same purpose, and with good effect, in palliating the paroxysms and preventing vomiting, but not in shortening the disease.

Various painful affections of the *ear* are mitigated by cocaine, such as *inflammation*, *neuralgia*, *tumors* of various sorts, etc. It greatly facilitates specular examination of the *auditory canal*, the use of instruments in this part, the catheterism of the *Eustachian tube*, and all operations upon either. Dr. Burnett (*Med. News*, xlvii. 100) enumerates as follows the limits of its usefulness: "It is not efficient when the pain is due to inflammation in the dense tissues of the external auditory canal, as in furuncles of the part, nor when acute inflammation occurs in chronically-thickened periosteal and mucous tissues in the tympanic cavity. It is, however, efficient to induce local anæsthesia, as a 4-per-cent. solution, in cases of not excessive congestion of the skin of the fundus of the auditory canal, and in the *membrana flaccida* of the drum membrane as it is observed in acute coryza. . . . But solutions of cocaine are not competent to produce local anæsthesia in the external auditory canal profound enough to permit painless incisions into it." Paracentesis of the *membrana tympani* is not painful enough to require local anæsthesia. It is, however, very difficult to anæsthetize this membrane: Kircher found that nothing short of a 20-per-cent. solution would have this effect; and Zaufel, confirming this statement, also mentions that in large perforations the mucous membrane can be reached and anæsthetized (*Philada. Med. Times*, xvi. 4). *Tinnitus* is palliated by cocaine, but, as this symptom usually depends on permanent conditions, palliation is of little value.

A 10- to 20-per-cent. solution of hydrochlorate of cocaine is a palliative of the pain and swelling of the lining membrane of the mouth in *mercurial salivation*. It is certain that *toothache* due to exposure of the pulp in a carious tooth is greatly mitigated by filling the cavity with cotton wool saturated with a solution of cocaine; it is also certain that rheumatic toothache and the pains of dentition are palliated by painting the painful gum with the same solution. The severe aching in the socket of a molar tooth which had just been extracted was at once relieved by filling the cavity with cocaine solution on cotton wool. On the other hand, its claim to prevent the pain caused by excavating sensitive teeth is denied by some dental surgeons, and it has been suggested that in these cases and in the extraction of teeth the expectation of the patients must be given due weight (*Ephemeris*, p. 762). Dr. Marshall of Chicago, having failed to prevent pain by using muriate of cocaine in excavating carious teeth, employed instead the *citrate*, which had been applied to this purpose in Germany. He found it much more efficient than the muriate, although when first applied it occasioned a stinging pain. The application usually made by him was of $\frac{1}{16}$ grain (*Jour. Amer. Med. Assoc.*, v. 290). Martindale and Tuttle report that a 5-per-cent. solution of the *oleate* of cocaine rubbed into the gum, and the hypodermic injection of 2 or 3 minims of a 4-per-cent. solution of it, enabled him to extract a tooth with little or no pain, and that a carious maxillary bone may be painlessly removed after a similar procedure. In extracting teeth about eight minutes should elapse between the application and the operation (*Med. Record*, xxviii. 651). Dr. Marshall, above quoted, on the other hand, did not find the oleate as efficient as the muriate or the citrate. Undoubtedly, the only way of rendering this method efficient is by injecting the solution into the gum in two doses. External *neuralgia* may be palliated by muriate of cocaine applied upon the superficial and painful points of the affected nerve, and probably better still by hypodermic injections.

In the various painful affections and operations involving the *urethra* and the *bladder* cocaine is incomparably the best anæsthetic. It renders the passage of all appropriate instruments painless, and therefore lessens the shock of operations requiring this procedure. Hence it has greatly facilitated the treatment of *urethral strictures* by dilatation or by cutting, and operations for removing *stone* in the bladder by crushing it. In one reported case the bladder was injected with half an ounce of a 4-per-cent. solution of cocaine, and the operation was begun and completed painlessly in a quarter of an hour (*Lancet*, Jan. 17, 1885). It is the most efficient agent in promoting the reduction of *phimosis* and *paraphimosis*, and in preventing pain in surgical operations for their cure. The operation of *circumcision* may be rendered painless by its use. Suppositories or

enemata containing it are very serviceable in cases of enlarged *prostate* causing vesical or rectal tenesmus, and also for *irritable bladder*. *Spasm* in the female as well as in the male urethra has been completely overcome by injections of this preparation; and there is no better remedy for *chordée* than it is when applied by the urethra or the rectum. In that most painfully distressing affection, *vaginism*, this preparation has repeatedly overcome a spasm that had recurred again and again for years, and has permitted the full and painless accomplishment of the generative act. In like manner it has been used in a 4-per-cent. ointment, or preferably in a watery solution, to mitigate the pains of *labor*, and especially of its first stage, and in appropriate forms to relieve *dysmenorrhœa* and other uterine pains, such as depend upon endometritis, lacerated cervix, etc. It has been employed with like advantage in many operations upon the vagina and uterus, as in those for *lacerated cervix*, *vesico-vaginal fistula*, extraction of a *vesical calculus* through the vagina (*Med. News*, xlvii. 602), etc. This preparation renders all exploratory examinations of the vagina and rectum painless, as well as such operations as those for *fissure*, *w'eer*, *hæmorrhoids*, *fistula*, etc. It is even claimed that it removes the chief objections to the operation of excision of piles. A 4-per-cent. solution may be painted over the swellings, and a minim of the same injected into each one at the muco-cutaneous junction. The rectal symptoms of *dysentery* may be greatly palliated by cocaine enemata or suppositories. Various small tumors have been removed without pain under the action of cocaine, which, as in the case of hæmorrhoids, have first been rendered insensitive by injecting a solution of it into the substance of each tumor and around its base; and in like manner foreign bodies lodged in the nostrils, in the ears, or in the tissues have been removed. In the latter cases it causes the swollen tissues to shrink as well as to become insensible. It has also been applied to removing *epithelioma* by means of the curette. In the operation for *hydrocele*, after the withdrawal of the liquid from the sac a drachm, more or less, of a 5-per-cent. solution of a cocaine salt is injected, which is allowed to bathe the interior during from five to ten minutes, after which the usual iodic solution may be employed. The pain of *burns* is greatly mitigated by a 2-per-cent. solution of this preparation; and *wounds* of the eye and other delicate parts may in like manner be so benumbed as to bear the necessary manipulation without difficulty; and *fractures* with displacement of the fragments belong to the same category. *Irritable tumor*, or *caruncle*, of the female urethra may be also rendered insensible before excision or destruction by cautery. *Abscesses* may be treated in like manner before puncture, and especially that very painful variety, *whitlow*. Even *amputations* have been performed with its aid. Dr. Mott has reported two cases of amputation of the finger treated hypodermically with cocaine, and also by means of Esmarch's bandage; and Dr. Varick, a case of amputation of the thigh, which in this manner was rendered nearly painless (*Med. Record*, xxix. 94; *Amer. Jour. of Med. Sci.*, Apr., 1886, p. 622). The excruciating pain caused by the operation for *ingrown toe-nail* has been entirely annulled by this anæsthetic applied in a 10-per-cent. solution so as to saturate the raw portions of the part (*Med. Record*, xxvii. 627, xxviii. 257; *Med. News*, xlvii. 34). *Vaccination* may be rendered altogether painless by painting a small area of skin with a strong solution of muriate of cocaine, and after a few minutes scraping away the epidermis from the spot and reapplying the anæsthetic. *Pruritus vulvæ* and other analogous affections are greatly palliated by this agent. In a case of spontaneous *hæmorrhage* from the gums, with ecchymoses elsewhere, bleeding was arrested by a 4-per-cent. solution of cocaine after various styptics had failed (*Philada. Med. Times*, xv. 380).

The application of cocaine to the treatment of internal diseases has not hitherto been very extensive, because its action has appeared to be almost entirely local except when it is taken in toxic doses. But for this reason it must have appropriate uses in *cancer*, *simple ulcer*, *neuralgia*, and *hæmorrhage* of the *stomach*, and in the *vomiting* occurring in sea-sickness and in pregnancy. In *sea-sickness* it has been employed with excellent results, according to Manassein (*Med. News*, xlvii. 320). He used the following formula: Muriate of cocaine 0.15 parts, rectified spirits of wine q. s., distilled water 150 parts; of which a teaspoonful was to be taken on starting for sea, and every two or three hours subsequently until the danger of sickness ceased. It seemed to act both as a prophylactic and a remedy. These results were confirmed by Wieherkiewicz (*Ibid.*, p. 626) and by Mason (*Med. Record*, xxix. 706). Otto, who employed $\frac{1}{4}$ to $\frac{1}{2}$ grain two or three times a day, was not so uniformly successful (*Ibid.*, xxviii. 656); and Bissell, who seems to have fairly tested the medicine, condemns it as worthless, and even injurious (*Ibid.*, p. 683). It has been employed to promote a cure in the *alcohol habit* and also in the *opium habit*, and success has been claimed for it when it was administered hypodermically as

well as by the stomach. But Smidt and Rank (*Med. News*, xlvii. 454) state that when given hypodermically, even in doses of $\frac{5}{8}$ gr., it sometimes caused *maniacal excitement*. It would seem, from the cases above cited, that this effect is peculiarly liable to occur in the slaves of opium and alcohol. Accurate observers generally agree with Erlenmeyer and Obersteiner that the action of cocaine is too fugitive to be permanently useful to these persons. Mosler claims to have cured a number of cases of *asthma* by the hypodermic use of salicylate of cocaine. As coca was originally employed to prevent or relieve excessive *fatigue*, so cocaine has been found to counteract the exhaustion experienced by *loss of sleep* and anxiety (*Boston Med. and Surg. Jour.*, March, 1885, p. 287); but it may be doubted whether coffee or tea would not have answered equally well. It has also been known to dissipate the gloom of *hypochondria* due to mental or physical causes of a temporary sort. In chronic melancholy with delusions it is useless. If the diuretic action which Drs. DaCosta, Penrose, and Bignon observed should be confirmed to this medicine, it may be added to the several remedies for *dropsy* and other disorders depending upon debility of the *heart*; and in *uræmia*, with scanty secretion of urine, it may be worth a trial.

Administration.—The mode of using cocaine has been fully set forth in the preceding pages, but some additional remarks may here be made. It is essential that the part to which the solution is to be applied should, if accessible, be cleansed of any secretion or deposit it may hold. For this purpose, especially in operations upon the eye, a solution of boric acid, 1 : 26, has been recommended. The strength of the solutions of cocaine salts employed has varied greatly. In ophthalmic surgery a 4-per-cent. solution is the most usual one, and it should be instilled at intervals of three or four minutes during a quarter of an hour. The portion of the solution used should be held in a vessel apart, to prevent contamination of the body of the liquid, and it should be applied with a dropping-tube rather than with a brush. All acid solutions are to be discarded. Some European ophthalmic surgeons have recommended 8–10-per-cent. solutions, but they are generally unnecessary. To economize and concentrate the anæsthetic, small disks, either of filtering-paper or fine linen or cotton fabric, or of gelatin, have been made use of. The last have been made each to hold $\frac{1}{2}$ grain of cocaine muriate. In Vienna solutions applied within the larynx have usually had a strength of from 15–20 per cent. A 4-per-cent. solution in almond oil has been used to anoint urethral instruments. A vaseline 2-per-cent. ointment may be applied with advantage to the eye when lachrymation is profuse. It is alleged (Corning) that by compressing the veins above the point at which the solution of cocaine is employed its action may be intensified and prolonged. In January, 1885 (*Med. News*, xlv. 49), Drs. Randolph and Dixon found that when a saturated solution of cocaine muriate in strong nitric acid was applied to the skin, it produced an eschar such as the acid alone would occasion, but more slowly than usual, and that the process was almost entirely painless. In October of the same year they applied this method to destroying cancerous growths by means of a paste formed by cocaine muriate, fused potassa, and vaseline, after having previously bathed the parts with a 10-per-cent. solution of the cocaine salt. Gilliam observed that a mixture of cocaine and salicylic acid rendered friable a supposed epithelioma of the face, and permitted the curette to be applied painlessly. Doubtless the action was in this, as in other cases, anæmiating as well as anæsthetic.

In cases of poisoning by cocaine it is probable that nitrite of amyl would be the proper antidote.

EXTRACTUM CASCARÆ SAGRADÆ, *Br.*—EXTRACT OF CASCARA SAGRADA.

Extractum Rhamni Purshiani.—*Extrait de cascara sagrada*, Fr.; *Cascara-sagrada-Extrakt*, G.

Preparation.—Take of Cascara Sagrada, in No. 40 powder, 1 pound; Proof Spirit, Distilled Water, of each a sufficiency. Mix the cascara with 2 pints (Imperial) of the spirit, and macerate in a closed vessel for 48 hours; then transfer to a percolator, and when the fluid ceases to pass continue the percolation with water until 3 pints of liquid have been collected or the cascara is exhausted. Evaporate the percolated liquid by a water-bath until the extract has acquired a suitable consistence.—*Br.*

Dose, from 2 to 8 grains (0.12–0.50 Gm.).

EXTRACTUM CASCARÆ SAGRADÆ LIQUIDUM, Br.—LIQUID EXTRACT OF CASCARA SAGRADA.

Extractum Rhamni Purshiani liquidum.—*Extrait liquide de cascara sagrada*, Fr.; *Flüssiges Cascara-sagrada-Extrakt*, G.

Preparation.—Take of Cascara Sagrada, in coarse powder, 1 pound; Rectified Spirit 4 fluidounces; Distilled Water a sufficiency. Boil the bark in three or four successive quantities of the water until exhausted. Evaporate the strained liquors by a water-bath to 12 ounces; when cold add the spirit, allow the mixture to remain for some hours, then filter, and make up to the volume of 16 fluidounces with distilled water.—Br.

The menstruum contains about 22 volumetric per cent. of alcohol. A stronger alcoholic menstruum like that directed for the fluid extract of frangula (see p. 633) would seem to be better adapted for the United States.

The dose is from $\frac{1}{2}$ to 2 fluidrachms (2–4 Gm.). (See p. 712.)

FABIANA.—FABIANA.

The branches of *Fabiana imbricata*, Ruiz et Pavon.

Nat. Ord.—Solanaceæ, Nicotianææ.

Origin and Description.—The plant is tree-like, or more frequently shrubby, and grows in sandy fields and on dry hills in Chili, where it is known as *pichi*. It is about 15 or 18 feet (4.5–5 M.) high, and bears single flowers terminating the numerous branches, and having a tubular white and purplish corolla $\frac{1}{2}$ to $\frac{3}{4}$ inch (12–19 Mm.) long, much exceeding the small calyx; the fruit is a small, two-celled, and two-valved capsule, containing few subglobular and angular seeds. The larger branches are covered with a thin, smoothish, somewhat warty, brown-gray bark, which adheres firmly to the yellowish tough wood. The younger branches are $\frac{1}{12}$ to $\frac{1}{8}$ inch (2–5 Mm.) thick, and are densely covered by the scale-like and closely-imbricated leaves, which are about $\frac{1}{24}$ inch (1 Mm.) long, sessile, ovate, entire, smooth, and of a bluish-green color. The drug has a peculiar aromatic odor and a disagreeable bitter taste.

Constituents.—Dr. Rusby's experiments (1885) indicated the presence of an alkaloid. Dr. Lyons (1886) obtained about 0.1 per cent. of this alkaloid, which is soluble in ether, forms crystallizable bitter salts, and yields precipitates with the usual reagents; also, a considerable quantity of bitter resin soluble in alcohol, ether, chloroform, and alkalies; a tasteless crystalline, neutral body, soluble in benzine and ether, and crystallizing from the alcoholic tincture; some volatile oil and a fluorescent compound resembling æsculin in behavior and possessing a very bitter taste. Benzine dissolves about 3 per cent., and ether about 33 per cent., of the drug; the alcoholic tincture yields a dense precipitate with water.

History and Uses.—*Pichi*, or *fabiana*, is a popular medicine in Chili for urinary disorders, and has even been credited with cures of stone and gravel. It was also used in dyspeptic, and especially hepatic, diseases. Relief obtained by a prominent citizen from its use in some vesical affection attracted attention, and induced Dr. Ramirez to inquire into its real value. It was found to resemble very closely that of various terebinthinate, balsamic, and other medicines that impregnate the urine and either heal or protect the mucous lining of the urinary passages. Like them, it is totally unfit for use in structural diseases of the kidneys. Several cases illustrating its utility in *vesical catarrh* have been published (Wyman, *Therapeutic Gaz.*, x. 221). The virtue attributed to it in hepatic disease is believed to depend upon its favorable influence upon gastric digestion. *Pichi* is regarded by the Chilean shepherds as very efficacious in a disease of sheep which is supposed to be hydatids of the liver.

A decoction prepared by boiling $\mathfrak{zj}$ (Gm. 32) of the coarsely-powdered twigs in 2 pints (Gm. 1000) of water should be taken in four equal portions in 24 hours; or a fluid extract, of which a tablespoonful represents $\mathfrak{zij}$ (Gm. 8) of the plant, may be given, diluted, at similar intervals.

FRANCISCEA.—FRANCISCEA.

Franciscea uniflora, Pohl.

Nat. Ord.—Solanaceæ, Salpiglossideæ.

Origin and Description.—This shrub is indigenous to Brazil, and, according to Martius (1829), is known there as *manacán*, and in some parts as *geratacáca* or *cam-*

gambá; in Para it is called *mercurio vegetal*. The stem, which is about 6 feet (1.8 M.) high, together with the root, has been introduced under the name of *manaca*, and is seen in commerce in pieces 6 or 8 inches (15–20 Cm.) long and $\frac{1}{4}$ to 1 inch (6–25 Mm.) thick. The bark is quite thin, adheres firmly to the wood, is smooth and dark brown, and on older parts scaly and rust-brown; the wood is reddish-yellow, tough and hard, and encloses a thin pith; the drug is inodorous and has a bitter taste. The leaves, which are also employed, are short-petioled, about 2 inches (5 Cm.) long, 1 inch (12 Mm.) broad, elliptic, acute, entire, and on the lower side grayish-green. The bell-shaped corolla is white and purplish, the fruit capsular, two-celled, and the seeds somewhat triangular and finely pitted. *White* and *red* manaca have been met with in commerce, the two kinds being probably of different origin; and in some parts of South America the bark of *Piscidia Erythrina*, *Jacquin*, is said to be known as manaca.

Constituents.—R. Lenardson (1884) analyzed red manaca, which, from the microscopic structure, he believes may belong to the Apocynaceæ. Besides fat, resin, 1.07 per cent. of ash, 11.25 starch, and various other compounds, a poisonous alkaloid, manacine, and a fluorescent compound were isolated. The latter is readily soluble in alcohol, chloroform, and spirit of ether, less freely in water, benzol, and ether, reduces alkaline copper solution, is not a glucoside, and is probably identical with *gelsemic acid*; the aqueous solution has an acid reaction, is yellow in transmitted light and blue in reflected light, the fluorescence being increased by ammonia. *Manacine* is a weak base, has a slight bitter taste, dialyzes readily, but has not been obtained in crystals; it dissolves readily in water, alcohol, and methyl alcohol, is insoluble or nearly so in other liquids, is easily decomposed in solution, with separation of a brown resin, the hydrochloric acid solution being more stable than others, and is precipitated from its more or less concentrated solution by the reagents for alkaloids, but not by alkalis; the precipitate by phospho-molybdic acid dissolves in potassa with a blue color. Characteristic color reactions were not observed. The alkaloid *franciscine*, which is stated to have been recently extracted from manaca, is probably the same as that just described.

History and Action.—In 1867, Edmon, who lived on the Amazon, reported that at Para the flowers of manaca, or francisceæ, were applied to indolent ulcers, and that a decoction of the root was regarded as a sovereign remedy for “rheumatism.” It was given in a decoction, which at first produced pains in the head and back, and afterward a profuse critical perspiration. Manaca, we are further told, is in small doses an emeto-cathartic diaphoretic and diuretic, and in large doses an acrid poison. It was employed not only in rheumatism, but in syphilis and other diseases “in which mercury is indicated” (*Therapeutic Gaz.*, v. 24). This description suggests the operation of sarsaparilla, guaiacum, and mezereum. From other sources we learn that the “rheumatism” here spoken of was the muscular and tendinous form of the disease, and also that the whole plant, but the root especially, acts as an irritant of the stomach and bowels, causing vomiting and purging, abortion in pregnancy, and even death (*Kobert's Jahrsbericht*, 1885, p. 310).

In 1882, Brewer studied the action of francisceæ. In man one or two fluidrachms (Gm. 4–8) of the fluid extract produced restlessness, which was allayed by walking, and was followed by a peculiar sense of fatigue, as if it cost an effort to move. From these observations, and from experiments on frogs and kittens, Dr. B. concluded—“1, that there is no effect upon the brain; 2, that the special senses are uninfluenced; 3, that the spinal cord is the chief field of action wherein (a) the motor centres are stimulated, and (b) the reflex function is abolished in the full physiological effect; 4, the cardiac reflex centre is depressed; 5, the respiratory reflex centre is depressed; 6, the glands are stimulated, especially the salivary, gastric, intestinal, and cutaneous, the liver and kidneys; 7, the duration of action is about three and a half hours; 8, the infusion prepared from the ground root contains the virtues of the drug” (*Therapeutic Gaz.*, iii. 326). Dragendorff and Lenardson found that manacine in the dose of $\frac{1}{8}$ grain (Gm. 0.01) occasioned in frogs muscular contraction, profuse sweating, and paralysis of the nerves of sensation. Larger doses paralyzed also the motor nerves: 5 grains (Gm. 0.30) administered to a cat produced diarrhœa, muscular twitching, and dyspnoea (*Kobert, loc. cit.*).

Uses.—Manaca has been employed almost exclusively in the treatment of “rheumatism,” but the reporters have not always distinguished between muscular and articular rheumatism, nor between the acute and chronic forms of both, between the simple and the syphilitic forms, etc., nor between the effects of the medicine and the natural tendency of the disease under favorable hygienic conditions to get well. The chief contributors to the history of this matter are Gottheil (*Med. Record*, xxiv. 258), Pepper

(*Therap. Gaz.*, Sept., 1882), Rogers (*Ibid.*, Dec., 1884, p. 532), Garland (*Boston Med. and Surg. Jour.*, July, 1885, p. 80), and Caldwell (*Med. Record*, xxvi. 31). After a careful comparison of the statements of these witnesses, we have reached the conclusion that manaca has little or no influence on the course or issue of articular rheumatism, and that it may be used, as numberless other diaphoretics, sedatives, etc. are employed, with more or less advantage in the so-called muscular form of the disease.

The fluid extract of manaca may be given in doses of fʒss-fʒj (Gm. 2-4).

GLYCERINUM ALUMINIS, Br.—GLYCERIN OF ALUM.

Glyceritum aluminis.—*Glycéré d'alum*, Fr.; *Alaunglycerit*, G.

Preparation.—Take of Alum, in powder, 1 ounce (1 part); Glycerin 5 fluidounces (5 fluid parts). Stir them together in a porcelain dish, gently applying heat until solution is effected. Set aside, and pour off the clear fluid from any deposited matter.—*Br.*

Uses.—Like all solutions of astringents in glycerin, this one is of inferior value to that of a watery solution of alum. It is, however, used, like other astringent glycerins, to check mucous secretions and slight passive hæmorrhages, to constrict soft granulations, relaxed membranes, etc.

GLYCERINUM PLUMBI SUBACETATIS, Br.—GLYCERIN OF SUBACETATE OF LEAD.

Glycéré de sous-acétate de plomb, Fr.; *Bleiglycerit*, G.

Preparation.—Take of Acetate of Lead 5 ounces; Oxide of Lead, in powder, 3½ ounces; Glycerin 20 fluidounces; Distilled Water 12 fluidounces. Mix together and boil for a quarter of an hour; then filter, and evaporate until the water is dissipated.—*Br.*

This is used for preparing Unguentum glycerini plumbi subacetatis, *Br.* (See p. 1564.)

GLYCERINUM TRAGACANTHÆ, Br.—GLYCERIN OF TRAGACANTH.

Glycéré de gomme adragante, Fr.; *Traganth-Glycerit*, G.

Preparation.—Take of Tragacanth, in powder, 110 grains (3 parts); Glycerin 1 fluidounce (12 fluid parts); Distilled Water 74 fluidgrains (2 fluid parts). Mix the tragacanth with the glycerin in a mortar, add the water, and rub until a translucent, homogeneous jelly is produced.—*Br.*

This preparation is useful as an excipient for many pill-masses. (See p. 1163.)

GYMNOCLADUS.—GYMNOCLADUS.

The seeds of *Gymnocladus canadensis*, *Lamarck*.

Nat. Ord.—Leguminosæ, Cæsalpinieæ.

Origin.—This handsome tree attains a height of about 70 feet (21 Mm.), grows from Tennessee to the Indian Territory, Wisconsin, and Western New York, and is cultivated for ornament; it is usually known as *coffee tree* or *Kentucky coffee tree*, and also as *Kentucky mahogany* on account of its rose-colored, close-grained wood, which is very tough and susceptible of a high polish. The oddly bipinnate leaves are 2 or 3 feet (0.6-0.9 M.) long, widely-branched; the lowest division has a single pair, the others from 7 to 13 ovate, short-stalked leaflets. The flowers are diœcious, racemose, greenish-white, and produce an oblong flattened brown legume about 6 to 8 inches (15-20 Cm.) long, with two light-brown ridges along each suture, and with more or less prominent veins on the valve. The four to six seeds are separated by transverse partitions, surrounded by a sweetish brown pulp, are flattish orbicular or roundish quadrangular, about ¾ inch (19 Mm.) broad and ⅓ inch (10 Mm.) thick, and have a whitish oblong hilum, to which a portion of the firm podosperm is attached; the testa is dark-brown, somewhat glossy, delicately veined, minutely pitted, and very hard and thick; the embryo is whitish, firm, granular, inodorous, has a bean-like taste, and consists of two closely-appressed, flattish cotyledons and a small curved radicle.

Constituents.—The plant has not been analyzed.

Action.—In a preliminary report upon this product by Dr. Bartholow it is stated that under the name of coffee-bean it has been known to be poisonous to flies. Its botanical affinities pointed to its analogy with physostigma, and an experimental investigation has demonstrated the fact. Applied to frogs, it affected sensibility first, and afterward motility, finally inducing a soporose and insensible condition. On the motor nervous

system its first action was exhibited by spastic rigidity, followed by paresis in the hind limbs. The motor nerves and the muscles, however, did not lose their irritability to the faradic current. Hence its operation was central, and not peripheral. It reduced the pulse-rate one half, and lowered, after having raised, arterial tension (*Amer. Jour. of Med. Sci.*, April, 1886, p. 582).

HYDROQUINONUM.—HYDROQUINONE.

Hydrokinone, Hydrochinone.

Formula $C_6H_4(OH)_2$. Molecular weight 110.

Preparation.—Hydroquinone was discovered by Wöhler (1844) amongst the products of dry distillation of kinic acid, and was shown by Strecker to be identical with Kawaller's *arcturin*. (See p. 1584.) It is also obtained on the dry distillation of the salts of succinic, gentisic, and oxysalicylic acid, and from aniline by oxidizing 2 parts of it with a solution of 5 parts of potassium dichromate in 60 parts of water and 16 parts of sulphuric acid; after the reaction has taken place sodium sulphite is added and the hydroquinone is dissolved by ether.

Properties.—Hydroquinone crystallizes in hexagonal colorless prisms, which are inodorous, have a sweetish taste, melt at $169^\circ C.$ ($336.2^\circ F.$), and sublime when carefully heated in shining scales resembling benzoic acid, but when rapidly heated are partly decomposed into yellow quinone and green quinhydrone. It dissolves at $15^\circ C.$ ($59^\circ F.$) in 17 parts of water, and is freely soluble in hot water, alcohol, and ether. The aqueous solution is colored red-brown with ammonia, and after having been mixed with solution of lead acetate yields with ammonia a yellowish precipitate changing to green. The rather concentrated solution gives with a small quantity of ferric chloride or of other oxidizing agents lustrous green needles of *quinhydrone*, $C_{12}H_{10}O_4$, and with an excess yellow *quinone*, $C_6H_2O_2$. From its two isomerides hydroquinone is distinguished as follows: *Resorcin* melts at $110^\circ C.$, boils at $271^\circ C.$ ($519.8^\circ F.$), and in aqueous solution is colored violet by ferric chloride; *pyrocatechin* melts at $104^\circ C.$ ($219.2^\circ F.$), boils at $245.5^\circ C.$ ($473.9^\circ F.$), and in aqueous solution assumes with ferric chloride a dark-green color, changing to violet with a little ammonia, sodium bicarbonate, or tartaric acid.

Action and Uses.—The action of hydroquinone is analogous to that of resorcin, but it is much more powerful. Experiments on frogs by Dr. Kinnicutt showed that 5 c. cm. of a 1:1000 solution produced convulsions in a few minutes and death in four and a half hours (*Med. Record*, xxvii. 593). In rabbits a half gram occasioned slight spasms, and three-quarters of a gram clonic convulsions, dyspnoea, dilatation of the arterioles, increased salivary and lachrymal secretions, diminution of reflex irritability, a rise of temperature of $2.7^\circ F.$, and death in one and a half hours. In another experiment, 4 grains (gram .25) given hypodermically excited violent muscular twitching, salivation, fecal and urinary discharges, and priapism, opisthotonos, and clonic spasms, followed by complete resolution. During the convulsions the temperature in the rectum rose to 104° or 105° (*Ibid.*, xxviii. 182). Beyer, experimenting with the frog and terrapin, concluded that hydroquinone reduces temperature mainly by increasing heat-radiation through its dilating action upon the veins, capillaries, and arterioles, while it diminishes the heat-production of the red corpuscles of the blood. In other words, its action is similar to that of kairine and thalline (*Amer. Jour. of Med. Sci.*, Apr., 1886, p. 391). Like them, it tends to paralyze the auricles and greatly to lower the tone of the walls of the veins; hence the danger to the animal experimented upon, says Beyer, "of bleeding to death into its own veins."

Dr. Kinnicutt found that single doses of 10 and 20 grains produced no appreciable symptoms in healthy persons. The pulse, respiration, and temperature were unaffected. A single dose of 40 grains was followed in ten minutes by a feeling of slight fullness in the head and dizziness, which disappeared in fifteen minutes.

Seifert found that in daily quantities of from 15 to 90 grains (Gm. 1-6), hydroquinone exercised a favorable antipyretic influence, and without any drawbacks, in *typhoid fever*, *pneumonia*, *scarlatina*, *pleurisy*, and *phthisis*, and that it maintained clearness of the mind and senses. In typhoid fever he observed that a 15-grain dose would cause a fall of temperature of from 1.8° to $3.6^\circ F.$, and sometimes much more than this. Dr. Kinnicutt (*loc. cit.*) confirmed these observations in cases of general tuberculosis, erysipelas, and septicæmia, and noted that the pulse and respiration subsided along with the temperature. He also observed that the medicine rendered the urine greenish-brown or dark-brown. As a general conclusion, he stated that hydroquinone is a safe and efficient

antipyretic, but that it does not arrest or abridge the specific febrile process. It may therefore be added to the list of agents which have been employed for the same purpose, but whose real utility in the treatment of febrile diseases has never been demonstrated.

Hydroquinone has been given in doses of from 15 to 20 grains to control the febrile exacerbations in phthisis. Where there is a tendency to a continuously high temperature, as in pneumonia, three or four such doses may be administered in the course of twenty-four hours. By the rectum the dose should be twice as large as that by the mouth.

HYPNONUM.—HYPNONE.

Acetophenone, Phenylmethyl-ketone.

Formula C_6H_5O or $C_6H_5.CO.CH_3$. Molecular weight 120.

Preparation.—The name hypnone has been proposed for phenylmethyl-ketone, which is formed by the action of zinc-methyl upon benzoyl chloride, and was first prepared by Friedell (1857) by the dry distillation of a mixture of molecular weights of benzoate and acetate of calcium, and subjecting the product to fractional distillation for the separation of acetone, benzol, and other compounds.

Properties.—Hypnone crystallizes readily in large laminæ, which, if pure, melt at $20.5^{\circ}C.$ ($68.9^{\circ}F.$) (Staedel, 1880). Liquid hypnone is colorless, mobile, very refragent, has a persistent odor of bitter almond and cherry-laurel water, and is not inflammable, but intensifies the combustion of substances impregnated with it. It boils at $200^{\circ}C.$ ($392^{\circ}F.$), has the specific gravity 1.032, remains for some time suspended in water in the form of globules, is insoluble in water, sparingly soluble in glycerin, and freely soluble in alcohol, ether, chloroform, benzol, and fixed oils. It is not affected by cold sulphuric acid, hydrochloric acid, or ferric chloride, is colored yellow by nitric acid, dissolves iodine and bromine freely and with the development of heat, and by chromic acid is converted into benzoic acid and carbon dioxide. From 38 to 40 drops of hypnone weigh one gram.

Pharmaceutical Preparations.—GELATIN CAPSULES OF HYPNONE, containing 2 drops of hypnone and 4 or 6 drops of expressed oil of almond, have been proposed by Limousin (1885).

SYRUP OF HYPNONE. Hypnone 1 drop, alcohol (60 per cent.) 1 Gm., syrup of orange-flovers 6 Gm. (Vigier).

ELIXIR OF HYPNONE. Hypnone 1 drop, alcohol 3 Gm., syrup of peppermint 3 Gm.

Action and Uses.—Dujardin-Beaumetz, who in 1885 described the virtues of this product, pronounced it to be a pure hypnotic, and gave it the name it bears. Administered hypodermically to a guinea-pig in the dose of from 7–15 grains, it occasioned a general torpor, followed by insensibility, and in five or six hours by death. It seemed to this physician to be a soporific rather than an anodyne. Its action on man was compared to that of chloral and also of paraldehyde. In the dose of 6–8 drops it usually caused tranquil sleep, but many persons did not feel its influence. Some immediately after swallowing it complained of heat in the throat and stomach, pricking in the nostrils, a slight cough, and even nausea or retching. Offensive eructations (of acetone) were apt to follow. Headache and slowing of the pulse were noted among its remoter effects. The sleep produced by it is said to be calm, and the awaking not attended with unpleasant feelings. These conclusions, more or less confirmed by Vigier, Limousin, Lailier, and others, are opposed by those of Hirt, who found the medicine absolutely null in its action when employed by him in hospital practice (*Centr. bl. f. d. g. Ther.*, iv. 260). Mairet and Combenvale also found it of little value.

Hypnone cannot be relied upon to secure sleep for those who cough or suffer pain, but only when wakefulness is due to nervous excitement.

It is best administered in capsules, each containing 4 drops (Gm. 0.10) of hypnone dissolved in almond oil.

INJECTIO APOMORPHINÆ HYPODERMICA, Br.—HYPODERMIC INJECTION OF APOMORPHINE.

Injection hypodermique (sous-cutanée) d'apomorphine, Fr.; Subcutane Apomorphin-Einspritzung, G.

Preparation.—Take of Hydrochlorate of Apomorphine 2 grains; Camphor-Water 100 minims. Dissolve and filter. The solution should be made as required for use.—Br.

Dose, by subcutaneous injection, 2 to 8 minims (Gm. 0.12–0.50). (See also p. 223.)

INJECTIO ERGOTINI HYPODERMICA, Br.—HYPODERMIC INJECTION OF ERGOTIN.

Injection hypodermique (sous-cutanée) d'ergotine, Fr.; *Subcutane Ergotin-Einspritzung*, G.

Preparation.—Take of Ergotin 100 grains; Camphor-Water 200 fluidgrains. Dissolve by stirring them together. The solution should be made as required for use.—*Br.*

Dose, by subcutaneous injection, 3 to 10 minims (Gm. 0.2–0.6). (See also p. 585.)

IODOLUM.—IODOL.

Pyrrol tetriodide.

Formula $C_4H_3NI_4$. Molecular weight 573.4.

Preparation.—Iodol is stated to be prepared from pyrrol by precipitating it with iodine dissolved in potassium iodide. Pyrrol was discovered by Runge (1834), and was first prepared pure by Anderson (1857). It exists in empyreumatic animal oil and in coal-tar, and is formed on the dry distillation of ammonium mucate and saccharate. It is prepared from animal oil by distilling its solution in somewhat diluted sulphuric acid, heating the distillate with potassa until the impurities have been volatilized, dissolving the potassium-pyrrol in water, and rectifying the separated oil.

Properties.—Iodol is a brown or reddish-brown powder, nearly inodorous, and decomposed by heat with the evolution of iodine, leaving a bulky charcoal as residue. It is almost insoluble in water, but dissolves freely in alcohol, ether, and chloroform; the alcoholic solution is not affected by the addition of glycerin, but is precipitated by water, and on being heated with nitric acid acquires a bright red color. Iodol gives with sulphuric acid a green color. It contains 88.3 per cent. of its weight of iodine.

Pharmaceutical Preparation.—IODOL GAUZE. Dissolve 1 part each of iodol and resin in 10 parts of alcohol, add 1 part of glycerin; saturate gauze with this mixture, and let dry.

Surgical Uses.—In 1885–86 iodol was tested in the syphilitic wards of Rome by Silber, Ciamiccian, and Mazzini as a dressing for ulcers. It acted upon them as a wholesome stimulant, like iodoform, but was free from the disagreeable smell of the latter agent. It was applied in the same manner—*i. e.* was sprinkled as a powder upon the raw surfaces or on prepared gauze or in a vaseline ointment, or suspended in glycerin or in an alcoholic solution diluted with glycerin (iodol 1 part, alcohol 16 parts, glycerin 34 parts). After from four to six applications the sores began to granulate, and the glandular swellings connected with them either subsided, or, if they went on to suppuration, were evacuated and injected with the iodol solution. This method availed in simple as well as in syphilitic ulcers and abscesses. It failed when the parts were gangrenous or sloughing. Iodol appears to act as a superficial caustic, and forms a whitish film on the ulcerated surface (Mazzini, *Centralblatt f. d. g. Therap.*, iv. 33). Experiments by Sternberg show that it is destitute of germicide powers (*Med. News*, xlviii. 150). As a dressing it does not display any poisonous qualities. In *lupus* it showed a healing power after injections of it were made into the morbid tissue; and in *fungous disease* of the joints its alcoholic solution shrivelled the vegetations, and a cure ensued. In *cancer* of the rectum and of the uterus it has promoted cicatrization when applied upon tampons. Applied as a fine powder or in a 20–30-per-cent. vaseline salve by Glässner, it was found useful in *pannus*, *corneal opacities*, *serous iritis*, and *blepharitis*; but it was not beneficial in *phlyctenous conjunctivitis*. In the same class of affections, but especially in the ulcerous forms of ophthalmia, it has been employed as an ointment, and with marked success, by Trousseau. He found the alcohol and glycerin solution too painful for ordinary use (*Bull. et Mém. de la Soc. de Thér.*, 1886, p. 99).

JACARANDA.—JACARANDA.

Jacaranda procera, Sprengel, s. *Bignonia Copaia*, Aublet, s. *B. Caroba*, Velloso.

Nat. Ord.—Bignoniaceæ.

Description.—This tree, which grows to the height of about 40 feet (12 M.), is found in the forests of Guiana and southward, and is known in Brazil as *caroba*. The root is of a deep red-brown and internally yellowish color; the bark is ash-gray; the leaves are bipinnate, the leaflets nearly sessile, varying in length between about $\frac{3}{4}$ and $2\frac{1}{2}$ inches (0.9 and 6 Cm.), elliptic, oblong or lance-oblong, rather obtuse, or more frequently acute, the base uneven and oblique, the margin entire or occasionally with one or two

irregular teeth, the texture rather leathery, the lower surface somewhat velvety near the veins, both sides with short hairs and glands; the odor is slight and the taste bitter and astringent.

Constituents.—Hesse (1880) found the leaves to be free from alkaloid and to contain mainly aromatic resin, which Peckolt (1881) named *carobone*; it exists in the leaves to the extent of 2.67 per cent., is greenish, amorphous, and has slight acid properties. Peckolt found also 1.44 caroba-balsam of a tonka-like odor, a bitter principle, tannin, crystallizable inodorous *carobin*, tasteless resin, and several acids. The bark likewise contains carobin, bitter principle, tannin, resin, etc.

Allied Plants.—Several plants of the same order are known in Brazil as caroba, and are more or less employed like the preceding—namely, *Jacaranda subrhombea*, *De Cand.*; *Jac. oxyphylla*, *Chamisso*; *Bignonia nodosa*, *Manso*; *Cibistax antisiphilitica*; *Martius*; and *Sparattosperma lithontripticum*, *Martius*.

Uses.—Mennell (*British Med. Jour.*, Feb. 14, 1885) and Wright (*Lancet*, Feb. 28, 1885) have employed this drug, the latter in *gonorrhœa* alone, and the former in the acute and chronic form of that disease and in *vesical* affections attended with purulent and muco-purulent urine. In its native country, Colombia, S. A., it is said to be used as a remedy for venereal diseases, and that its administration causes neither nausea nor any other inconvenience. It may be given, as a fluid extract made from the leaf, in doses of from 20 to 30 minims three or four times a day.

Carobin, the active principle of *jacaranda*, has been regarded as nearly analogous to sarsaparillin. Peckolt recommended it in doses of about 1 grain (Gm. 0.05) in syphilis and scrofula.

LAMELLÆ, *Br.*—DISCS, GELATIN-DISCS.

Laminæ gelatinosæ.—*Disques de gélatine*, *Fr.*; *Gelatinplatten*, *G.*

The preparation of gelatin-discs or *medicated gelatin* has been briefly described on page 725. They are usually made about 1 Mm. ($\frac{1}{25}$ inch) thick, and a small quantity of glycerin is added to the mixture to prevent the discs from becoming hard and brittle on keeping. The British Pharmacopœia has admitted three kinds of medicated gelatin-discs, but does not give formulas for their preparation. In each case the discs are to be of gelatin, with some glycerin, and each is to weigh about 1.3 Mgm. ($\frac{1}{50}$ grain).

LAMELLÆ ATROPINÆ, *Br.* Discs of atropine, *E.*; *Disques d'atropine*, *Fr.*; *Atropinplättchen*, *G.*—Each disc is to contain 0.00013 Gm. = 0.13 Mgm. ($\frac{1}{7500}$ grain) of sulphate of atropine.

LAMELLÆ COCAINÆ, *Br.* Discs of cocaine, *E.*; *Disques de cocaïne*, *Fr.*; *Cocainplättchen*, *G.*—Each disc is to contain 0.00032 Gm. = 0.32 Mgm. ($\frac{1}{2000}$ grain) of hydrochlorate of cocaine.

LAMELLÆ PHYSOSTIGMINÆ, *Br.* Discs of physostigmine, *E.*; *Disques d'ésérine*, *Fr.*; *Physostigminplättchen*, *G.* Each disc is to contain 0.000064 Gm. = 0.064 Mgm. ($\frac{1}{15625}$ grain) of physostigmine.

LANOLINUM.—LANOLIN.

The fat prepared from sheep's wool.

Origin and Preparation.—The keratin-holding tissues, such as sheep's wool, hair, feathers, skin, hoofs, etc., contain peculiar fats which in wool are partly combined with potassium and are known as *suint* (*Wollschweiss*, *G.*). The total amount is between 30 and 45 per cent. of the weight of the wool, of which, on the average, about 15 per cent. is soluble in water. In the scouring and washing process to which crude wool is subjected it is heated with a weak solution of alkali; the emulsion thus obtained is treated with sulphuric acid, and the fat separated from the impurities by expression. In this condition it is of a dark-brown or blackish color, and has a disagreeable animal odor. For further purification the fat is boiled with diluted sulphuric acid, washed with water, and bleached by treatment with potassium chlorate or chromate and sulphuric acid. Treatment of the crude fat with charcoal has but little effect. A much purer fat is at once obtained from wool which has been thoroughly washed with water and cleaned from dirt by exhausting it with solvents which do not injure the softness and flexibility of the wool, such as benzoin, benzol, or ether; the pure fat is left behind on distilling off the solvent.

Properties.—Lanolin is a yellowish, light-brown, or pale greenish-brown solid, greasy

to the touch, of a rather tough consistence, and should have the characteristic odor of wool only in a slight degree. Rubbed on the skin, it renders the latter greasy, but is gradually absorbed, the odor disappearing at the same time. Its density is .973, it melts at about 40° C. (104° F.), burns with a smoky flame, is soluble in the usual solvents for fats, but, unlike the latter, may be mixed with its own weight of water by trituration in a mortar, and on boiling with alkalis is saponified with considerable difficulty. Jaffé and Darmstaedter recommend testing the purity of lanolin by heating a little of it with caustic soda solution, when ammonia should not be given off; by heating 1 part of lanolin with 5 parts of water, when the melted lanolin should form a clear layer upon the water, and the latter should not contain any glycerin; and by kneading lanolin under water, when it should take up its own weight of water without becoming soapy. The solution of lanolin in glacial acetic acid, on the addition of concentrated sulphuric acid, acquires a rose color, which rapidly changes to blue and green. Lanolin mixed with water is less tough, and when kept in the melted condition separates the water.

Composition.—Lanolin does not contain any glycerides, but is a mixture of the cholesterin-ether of stearic acid, $C_{26}H_{43}C_{18}H_{35}O_2$, with those of palmitic, oleic, valerianic, benzoic, and probably other acids, and with a resin-like body and coloring-matter.

Pharmaceutical Uses.—For the preparation of ointments, more particularly such as are to be combined with aqueous liquids.

Medical Action and Uses.—The medicinal employment of the fat obtained from sheep's wool is very ancient. Pliny says that its uses are numberless, and he describes the manner of procuring it from the wool beneath the fore legs and the thighs of the animal by boiling the wool in water and skimming off the floating fat (*Hist. Nat.*, xxix. 10). These directions were rehearsed from age to age. In the seventeenth century they were repeated by Culpepper. More recently, according to Strumpf (*Handbuch*, i. 128), this fat had a place in the Spanish Pharmacopœia, and uncleansed wool was employed as a dressing for serofulous and other swellings, and also in gout and rheumatism. The value of lanolin in medicine is due to its power of absorbing its own weight of water and nearly twice its weight of glycerin. It is not at all irritating to the skin, but does not render it as supple as some other emollients do. The former property makes it a valuable excipient for many medicines which are applied to the skin, including metallic mercury and mercurial salts, iodoform, potassium iodide, chrysarobin, etc. After friction with a lanolin ointment containing $\frac{1}{100}$ of corrosive sublimate a metallic taste may be perceived in the mouth; and a 5-per-cent. carbolic-acid ointment prepared with it occasions a sense of numbness in the skin in the course of a few minutes, but does not irritate it. Rubbed with the finger upon the back of the hand, it is promptly absorbed, leaving the skin dry and with a feeling of tension.

Lassar (*Berlin klin. Wochenschrift*, 1886, No. 5) made use of lanolin ointments in 400 cases of diseases of the skin. A case of *eczema* of the scalp and face was cured in a week by a 2-per-cent. lanolin-salicylic ointment. One of contagious *impetigo* was cured in ten days by means of a paste composed of salicylic acid 2 parts, lanolin 50 parts, and oxide of zinc and starch, of each 24 parts. *Pityriasis versicolor* with extreme itching was successfully treated by means of an ointment containing salicylic acid 2, sulphur 10, and lanolin 88 parts. In many cases of inveterate *scabies*, in *tylosis*, and especially in *syccosis* and other acneiform eruptions, it was often of great service, and in all affections in which the epidermis is thickened or hard it lessened this obstacle to cure. The following paste is particularly recommended in scabies: Naphthol 5–10, green soap, chalk, sulphur, and lanolin, of each 25 parts; and in *psoriasis* an ointment made with lanolin and 25 per cent. of chrysarobin. Lanolin forms the most appropriate excipient for ointments of iodine, potassium iodide, etc., to be applied by friction to *glandular swellings*; for all such as are applied to the *hairy scalp*; and also for those employed in *seborrhœa*, *chilblain*, *chapped hands*, *pruritus ani* and *vulvæ*, etc. If the object be to render the skin softer, it may be desirable sometimes to dilute the thicker ointment with 20 per cent. of vaseline; but in superficial affections, and where a lenitive and protective action is desired, lanolin may be applied alone after thoroughly cleansing the skin with warm water and soap, bran, or Indian corn meal.

The results obtained by Lassar have been fully confirmed by those of O. Liebreich, who tested its virtues clinically. He recommends it, on account of its unirritating qualities, as the best unguent for *massage*. It appears to form the best excipient for chrysarobin in the treatment of *favus*. A number of formulæ for the use of this preparation have been published by Liebreich (*Brit. Med. Jour.*, Feb., 1886, p. 282; and *Braithwaite's Retrospect*, xciii. 159).

LIQUOR FERRI ACETATIS, Br.—SOLUTION OF ACETATE OF IRON.

Preparation.—Take of Strong Solution of Acetate of Iron 5 fluidounces; Distilled Water sufficient to produce after admixture 20 fluidounces.—*Br.*

This solution has the specific gravity 1.031, and is of the same strength as the tincture of acetate of iron, *Br.*

Dose, from 5 to 30 minims (Gm. 0.30–2).

LIQUOR FERRI ACETATIS FORTIOR, Br.—STRONG SOLUTION OF ACETATE OF IRON.

Preparation.—Take of Solution of Persulphate of Iron 5 fluidounces; Glacial Acetic Acid 3 fluidounces; Solution of Ammonia, Distilled Water, of each sufficient. Mix 8 fluidounces of solution of ammonia with 1 pint of distilled water; to this gradually add the solution of persulphate of iron, previously diluted with about a pint of distilled water; stir the whole thoroughly, taking care that the ammonia is, even finally, in slight excess, as indicated by the odor of the mixture. Let the whole stand for 2 hours, stirring occasionally; then put it on a calico filter, and when the liquid has drained away, wash the precipitated ferric hydrate with distilled water until the liquid which passes through the filter ceases to give a precipitate with solution of chloride of barium. Let the ferric hydrate drain; squeeze it to remove superfluous moisture; dissolve it in the glacial acetic acid; and make the volume up to 10 fluidounces with distilled water. Allow any insoluble matter to subside, and pour off the clear solution.—*Br.*

(For explanations of the process and for the chemistry of ferric acetate see pp. 899 and 900.) The strong solution of the *Br. P.* is about one-third stronger than the liquor of the *P. G.*, and consists of normal acetate with excess of acetic acid. Its specific gravity is 1.127, and it contains 6.4 per cent. of iron or 9.2 per cent. of Fe_2O_3 . 1 fluidrachm of it, diluted with water, yields with ammonia 5.7 grains of ferric oxide.

MENTHOL, Br.—MENTHOL.

Menthol, Fr., G.

Formula $\text{C}_{10}\text{H}_{20}\text{O}$. Molecular weight 156.

Origin and Preparation.—The Chinese and Japanese solid oil of peppermint, which consists mainly of menthol, was shown by E. M. Holmes to be prepared from the varieties *glabrata* and *piperascens* of *Mentha arvensis*, *De Candolle*. Within the past few years A. M. Todd has prepared a very handsomely crystallized and perfectly dry menthol from oil of peppermint distilled from *Mentha piperita* grown in the United States. This volatile oil, carefully rectified by steam, is cooled by means of ice and salt to -22.2°C . (-8°F .), and after it has solidified the temperature is allowed to rise very slowly, the liquid portion being drained off from time to time. This article has become known in our commerce as *pipmenthol*. The yield is about 20 per cent. of the weight of the oil.

Properties.—Menthol forms colorless acicular glossy crystals, which, seen in quantity, have a white appearance; if rapidly congealed the crystals are thin, stellately arranged, and of a satiny lustre. They melt at 42°C . (107.6°F .) to a colorless liquid, boiling at 212°C . (413.6°F .), and have an agreeable odor and taste of peppermint, producing, if air is inhaled, a sensation of coolness. The Chinese menthol appears either in fused crystalline masses or in colorless acicular crystals, which are more or less moist from adhering oil, melt at about 41°C . (105.8°F .), and differ somewhat in odor from that of pipmenthol; the melting-point is increased to 42°C . by prolonged exposure to the air. Menthol dissolves sparingly in water, but is freely soluble in alcohol, ether, chloroform, and other solvents of volatile oils; the solutions have a neutral reaction to test-paper. Boiled with sulphuric acid diluted with half its volume of water, menthol acquires an indigo-blue or ultramarine color, the acid becoming brown. Menthol should be entirely volatilized by the heat of a water-bath (absence of magnesium sulphate and other saline or waxy impurities). In contact with thymol, which has a higher melting-point, it becomes liquid (Flückiger, 1885). Triturated with an equal weight of chloral at 35°C . (95°F .), an oily colorless liquid is produced, soluble in alcohol, benzin, chloroform, ether, and carbon bisulphide, and on being mixed with sulphuric acid acquiring a blue color, the mixture yielding with alcohol a nearly colorless solution (H. V. Becker, 1886).

Uses.—To the statements made under *Oleum menthæ piperitæ* (p. 1067) the following may be added: Menthol in a solid form has but a trifling advantage over the oil of peppermint. Like it, and like various other essential oils, counter-irritants, and anodynes, it

is a palliative of superficial *neuralgia*. It has been employed to relieve itching and burning pain in *pruritus ani*, *eczema*, *zora*, *bites of insects*, superficial *burns* and *scalds*, *boils*, *carbuncles*, and all analogous affections. It has been tried to obtund the sensibility of the *pharynx* and *larynx* in manipulations and operations involving these parts, but is not as eligible as cocaine. For some of its applications it may be mixed with cocaine or with chloral.

PHORMIUM.—PHORMIUM.

New Zealand flax (hemp), E.; *Lin (Chanvre) de la Nouvelle-Zélande*, Fr.; *Flachslilie*, *Neuseeländischer Flachs*, G.

The root and leaf-bases of *Phormium tenax*, *Forster*.

Nat. Ord.—Liliaceæ, Liliæ.

Origin and Description.—The plant is indigenous to New Zealand and the Chatham Islands, has been introduced into Australia, the Azores, and other countries, and in temperate climates is cultivated as an ornamental hot-house plant. It has a fleshy rhizome, beset with nearly simple roots, and sending forth from its end a tuft of leathery linear-lanceolate leaves, which are from 5 to 8 feet (1.5–2.4 M.) long and 3 to 4 inches (7–10 Cm.) broad. The leaves, sufficiently matured, are cut off above their base, the remaining portion attached to the rhizome, and, with the rootlets, constituting the drug. The straight fibres of the leaves, separated from the other tissue, are brought into commerce as New Zealand flax; they are cream-colored, of a silky lustre, tough, but rougher than hemp, and are mainly used for cordage. The flowering stalk attains a height of about 15 feet (4.5 M.).

Constituents.—The drug has not been subjected to analysis.

Uses.—New Zealand flax was made use of in a strong decoction by Mr. Monckton (*Therapeutic Gaz.*, ix. 320) as a dressing for all manner of lesions of continuity, including *lacerations* and *amputations*. As it readily deteriorated by fermentation, he added to each quart of the decoction about an ounce of equal parts of carbolic acid and glycerin. With this he washed the part and maintained cotton wool or lint soaked in it constantly, and declared that the discharges were altogether insignificant. Without further knowledge of the constitution and qualities of *Phormium tenax*, it would be unjust to suggest that its value is perhaps overestimated; but unless the results of its use without the adjunction of carbolic acid were furnished, we can scarcely refuse to the latter agent a large part in the success of the compound.

SULPHOPHENOLUM.—SULPHOPHENOL.

Sulphocarbolic acid, Aseptol, Orthophenol-sulphonic acid.

Formula $C_6H_4.OH.SO_3H$. Molecular weight 174.

Preparation.—Two of the three sulphophenols are obtained by the action of sulphuric acid upon carbolic acid, the para-compound being produced at an elevated temperature, while the ortho-compound is formed in the cold by leaving together for a week 10 parts of carbolic acid and 12 parts of sulphuric acid, after which time the excess of the latter is removed by calcium carbonate or barium carbonate.

Properties.—Sulphophenol is a reddish or amber-colored viscous liquid having the specific gravity 1.45, an odor resembling that of carbolic acid, and a caustic taste. It is readily soluble in water, alcohol, and glycerin. The commercial article, known as aseptol, is mostly a straw-colored, slightly caustic liquid of the density 1.167, and containing between 30 and 35 per cent. of sulphophenol. Its aqueous solution should give no precipitate with barium chloride.

Action and Uses.—In 1884, Vigier described the action and uses of this compound (*Bulletin et Mém. de la Soc. de Thérap.*, Juin, 1884, p. 82); he stated that it was not caustic, nor, like carbolic acid, poisonous in its medicinal use. He satisfied himself of its power to arrest fermentation, showing that urine containing it in the proportion of $\frac{1}{4}$ of 1 per cent. might be kept for months without putrefying, and that blood and other animal matters remained equally unchanged under its influence. Fermentable liquids containing glucose were protected from change by the addition to them of 1 part of this compound to 1000 of the liquid. Solutions of it in the proportion of from 5 to 10 per cent., and properly diluted, did not act poisonously when given internally, although its coagulating power on the contents of the stomach was decided. In this, as in other respects, it was contrasted with carbolic acid. Injected into the veins of dogs, solutions

varying in strength from 1 to 20 per cent., and in small portions at a time, did not occasion much disorder of the functions, but stronger solutions or in greater bulk rendered the heart and respiration irregular, and brought on copious frothy salivation, etc. When the individual injections amounted to f̄ss (14 c.c.), containing 42 grains (Gm. 2.80) of sulphophenol, the animal was bent backward spasmodically, respiration and circulation were suspended, a copious discharge of urine took place, the pupils were dilated, and the animal died. The cause of death was disclosed by the coagulated blood, especially on the right side of the heart, and the blood-vessels communicating with it. Animals thus poisoned resist putrefaction indefinitely. Numerous wounds in different animals, including fresh granulating and suppurating wounds, and also abscesses, were washed with a 10-per-cent. solution, with the result of quickening granulation, arresting suppuration and fetid secretions, and hastening the cure. The application did not appear to cause pain, and no symptoms of poisoning by the preparation arose.

Vigier states that in the course of a day he took about 150 grains of sulphophenol dissolved in 2 pints of water without experiencing any inconvenience. Lightly applied to the tongue, it caused a slight pricking and astringent sensation; the mucous membrane was whitened, and the epithelium exfoliated on the following day. In view of its antiseptic virtues, Vigier recommends solutions of sulphophenol (1-5 per cent.) as an ordinary dressing for *wounds*, in various diseases of the *uterus*, *bladder*, and *urethra*, in open *cancer*, and in fetid *ulcers* of every sort. He particularly insists upon its superiority over carbolic acid and corrosive sublimate in *obstetrical* medicine and surgery for its freedom from smell and irritating properties. He recommends solutions of 1-10 per cent. as lotions in *eruptive fevers* and in *parasitic diseases of the skin*.

THALLINÆ SULPHAS.—SULPHATE OF THALLINE.

Thalline, E., Fr.; *Thallin*, *Thallinsulfat*, G.

Formula $(C_{10}H_{13}NO)_2H_2SO_4 \cdot 2H_2O$. Molecular weight 460.

Preparation.—The base thalline, which is the methyl ether of tetrahydro-paraoxy-*chinoline*, and its salts were discovered by Skraup in 1884, and is prepared from *para-guainanisol* by treatment with tin and hydrochloric acid. This last-named compound is an oily base, and is obtained by heating to about 145° C. (293° F.) a mixture of *para-midoanisol*, *paranitranisol* (or another nitro-compound), glycerin, and sulphuric acid. The base thalline forms thick white prisms, which are freely soluble in alcohol, ether, and benzol, but dissolve sparingly in benzin and water. The sulphate, which has become known by the name of the base, thalline, is formed by dissolving the latter in dilute sulphuric acid and crystallizing or granulating.

Properties.—Thalline sulphate is usually seen in the form of a white or whitish granular crystalline powder, which is permanent in the air, and has a slight anise-like odor and a nauseous, bitter, saline, and pungent taste, becoming more agreeable and aromatic in dilute solutions. The salt is freely soluble in hot water, sparingly soluble in chloroform and in ether, and requires for solution 5 parts of cold water and 100 parts of alcohol, the solutions becoming darker on exposure to light. A solution of the salt in 10,000 parts of water acquires an emerald-green color on the addition of a little ferric chloride or other oxidizing agent, the color being not altered by sulphuric acid, but changed to purplish, reddish, or yellow by reducing agents. The solution of thalline is colored deep red on being heated with fuming nitric acid; it is not affected by tannin or mercuric chloride, but yields a yellow precipitate with picric acid, and alkalies separate from it the base in oily drops, becoming crystalline and having a coumarin-like odor.

Allied Salt.—THALLINE TARTRATE closely resembles the sulphate in appearance and taste, but has a coumarin-like odor, and is much less soluble, requiring at 15° C. (59° F.) about 10 parts of water.

Action and Uses.—According to Brouardel and Loye, thalline deteriorates the hæmoglobin of the blood, converting it into methæmoglobin, and thereby diminishing its oxidizing power. Huchard, while he failed to detect the latter product, observed a great reduction in the oxyhæmoglobin, in consequence of which guinea-pigs employed in his experiments perished as if they were anæmiated. He also found that thalline was rapidly eliminated in the urine, and, indeed, in all the secretions (*Bull. et Mém. de la Soc. de Thérap.*, Avril, 1885, p. 46). The experiments of Beyer (*Amer. Jour. of Med. Sci.*, Apr., 1886, p. 386) on the frog and terrapin proved that "repeated thallinization of the heart is followed by a peculiar shrinkage of the organ, during which it presents the dark color of thallinized blood;" that, as had already been shown, "it reduces the temperature by

diminishing heat-production and increasing heat-radiation;" and that "its influence upon the blood-corpuscles is sufficient to condemn it" as a medicine.

In man, thalline produces a fall of temperature which is nearly always attended with profuse sweating; it reaches the minimum in from one to three hours, and recovers its former height in from four to five hours, but sometimes more rapidly, and in that case chilliness is experienced. Yet not unusually both chill and sweat are wanting. The rise and subsequent fall of temperature are more rapid than are caused by antipyrine, but less so than kairine occasions; yet it maintains the maximum longer than is done by either of these preparations (Mengazzini; Anseroff). After its completed action the temperature is apt to rise higher than at first. According to Welt, a watery diarrhœa is frequently produced by thalline, and vomiting in about 7 per cent. of the cases (*Deutsch. Arch. f. klin. Med.*, Dec. 3, 1885). The repeated administration of medicinal doses now and then occasions a papular erythema, especially of the limbs. Some clinical observations of Dr. Griffith on the use of thalline point to its sometimes causing profuse sweating in phthisis. Twice in thirty-eight cases of this disease and in acute febrile affections a decided depression of strength occurred, which "indicated that it must be given with great care to debilitated subjects" (*Med. News*, xlviii. 370). Jaccoud maintained, but we believe without adequate evidence, that the reduction of temperature produced by thalline is limited to the surface of the body; and he adds that this peripheral cooling does not benefit, but rather weakens (*Archives gén.*, Dec., 1885, p. 796).

Thalline is unquestionably an antipyretic, probably the most certain and powerful of its class, and for that reason calls for the condemnation which was pronounced upon it by Jaksch in Vienna, who first brought the preparation into notice. "Drugs," he said, "which are only antipyretics are of very little use" (*Times and Gaz.*, Dec., 1884, p. 797). In this sentence Prof. Nothnagel concurred, protesting against the indiscriminate use of "antipyretics," as if fever were a substantial disease, and not the outcome of necessary chemical and physiological changes in the tissue-elements. We have long inculcated the opinion he thus expressed: "Fever is not a symptom to be removed in every case. According to my conviction, which is also that of many other investigators, it is a very beneficial phenomenon—one of those processes of reaction which one must look upon as compensatory. . . . Although we may succeed in lowering the temperature, we do not shorten the duration of an acute fever by a single day. . . . In general, a temperature that does not exceed 104° F. does not injure the patient." In relapsing fever the temperature often rises to 105° F., and even to 106° F., without in the least disturbing the mind, and the patient recovers—exhausted indeed, but not otherwise injured. Jaksch claimed for thalline that it provoked neither vomiting, cyanosis, nor collapse, and that only occasionally did it produce sweating and rigors. Now that this judgment is known to be too favorable, we may all the more readily accept his further conclusions, confirmed by later observers. He confessed that the medicine neither shortens nor radically modifies febrile affections, including intermittent fever, acute articular rheumatism, measles, puerperal septicæmia, pneumonia, erysipelas, and tuberculosis. "Fever, indeed, it suppressed, but all the rest remained unchanged" (*Wiener med. Wochenschr.*, No. 48, 1884). Hallopeau pronounced a similar judgment in the matter (*Bull. et Mém. Soc. de Thérap.*, 1885, p. 57). Maragliano's observations confirm the conclusions already stated. He found that in non-febrile states the temperature was but slightly affected by thalline; that in these, as in febrile states, it occasioned a decided loss of heat; that during its action the excretion of urea and the elimination of carbonic acid are diminished; and that it also lessens the absorption of oxygen by the blood in the lungs (*Zeitschr. f. k. Med.*, 1886, x. 462).

Thalline salts, the sulphate or the tartrate, may be prescribed in doses of from 4 to 12 grains (Gm. 0.25–0.75). They may be administered in powder, contained in wafers, or in solution. They are said to act perfectly through the rectum. Hypodermically, they do not produce abscess or otherwise irritate the tissues.

URETHANUM.—URETHANE.

Ethyl carbamate, E.; *Uréthane*, Fr.; *Uræthan*, G.

Formula $C_3H_7NO_2$ or $CO.NH_2.OC_2H_5$. Molecular weight 89.

Preparation.—Urethane was discovered by Dumas in 1833, and may be prepared, according to Cahours, by leaving ethyl carbonate in contact with ammonia, when urethane and alcohol are produced. A similar reaction takes place between ethyl chlorocarbonate and ammonia, resulting, however, in the production of ammonium chloride and urethane.

The same compound is also formed by heating urea (or preferably nitrate of urea) with alcohol, when ammonia will be liberated. Numerous other processes are known.

Properties.—Urethane crystallizes in white or colorless tables, which are not deliquescent, are inodorous, have a pleasant saline taste, and melt below 100° C., the liquid congealing again in a pearly crystalline mass resembling spermaceti. Urethane boils at 180° C. (356° F.), but sublimes at a much lower temperature; it is readily soluble in water, alcohol, and ether. Heated above its melting-point in the presence of moisture, it is partly decomposed with the evolution of ammonia; and when heated with ammonia urea is formed. It is decomposed by potassa, with the formation of potassium carbonate, ammonia, and alcohol.

Action and Uses.—Schmiedeberg, in his experiments with urethane upon frogs (*Practitioner*, xxxv. 279), found that by gradually increasing the dose he could produce various degrees of hypnotism in these animals, from mere dulness to profound and prolonged stupor. Huchard gave to a rabbit three successive doses of 18 grains (Gm. 1.25): the temperature and respiration declined, and in about half an hour the animal fell into a state of cataleptic insensibility of several hours' duration. Smaller doses only rendered it dull and torpid. A rabbit was kept insensible for a whole day by repeated hypodermic injections, amounting in all to 45 grains (Gm. 13), and another animal of the same species was not killed by 135 grains (Gm. 9) administered in a similar manner (*Bull. de therap.*, ex. 104). The punctures became sore, but other observers—and notably Coze—declare that urethane is not a local irritant. A solution containing 120 grains and thrown into the peritoneal cavity caused no ill results. Under the primary action of this compound Coze found that the blood-pressure increases, but soon returns to its normal standard; that it causes the blood to absorb an increased proportion of oxygen, and probably to retain it with abnormal tenacity; and that it slows the respiration and lowers the temperature (*Ibid.*, ex. 337). The most important fact determined by Coze is the power of urethane as an antidote to *strychnine*. It was manifested in frogs, guinea-pigs, rabbits, and dogs (*Ibid.*, ex. 342).

In 1885, Jaksch found that in man a dose of from 8–15 grains of urethane produced peaceful slumber of several hours' duration (*Times and Gaz.*, Oct., 1885, p. 485). It did not appear to exert any direct anodyne influence. Friedländer's investigations seemed to prove that even in the minute dose of $\frac{1}{30}$ grain (Gm. 0.001) it occasioned lassitude and depression, with retching and vomiting. The visible mucous membranes turned pale, the pupils acted irregularly, and the pulse and heart failed. But no such effects from similar doses have been noted by other observers. While suffering from pain he took a drachm of urethane, and secured thereby a comfortable night's rest, while on the following night it excited him (*Therap. Gaz.*, ix. 852). The inharmonious statements concerning the effects of this preparation do not appear to diminish as its use becomes less restricted. Hübner and Sticker affirm that it occasions no unpleasant after-effects, and that a dose of 30 grains is not less hypnotic than a dose of 60 grains; but Otto and Koenig allege that it is more apt than paraldehyde to occasion vomiting, and that its narcotic action is less decided. They also accuse it of producing loss of appetite, etc. On the whole, the action of this preparation resembles that of paraldehyde, over which it has the advantage of being free from unpleasant smell and taste.

The therapeutical value of urethane has not yet (Oct., 1886) been sufficiently tested. Kroepelin found it a useful hypnotic for melancholic patients suffering from *insomnia* and in cases of "mild excitement or depression accompanied by exhaustion or depressed nutrition" (*Med. News*, xlviii. 626). Otto and Koenig, on the other hand, claim it to have had a very favorable action in violence of a hysterical or epileptic nature, and Rottenbiller seems to have used it with general advantage for the relief of *insomnia* in the insane in doses of from 30 to 60 grains. He also employed with similar results hypodermic injections, two of which, of 4 grains each, sufficed (*Therapeut. Gaz.*, x. 474). A case of traumatic *tetanus* in a boy of fifteen years is related as having been cured by urethane given in 4-grain doses every two hours—a result that it would be desirable to have confirmed by experience. A case of severe and obstinate *chorea* is reported in which urethane procured sleep and tranquillity after the bromides had failed to do so (*Boston Med. and Surg. Jour.*, May, 1886, p. 419). In many cases it has been found an efficient substitute for opiates.

Urethane may be given in capsules or in a flavored and sweetened watery solution. Its average dose is about 15 grains, but three times as much has frequently been taken without untoward effects.

APPENDIX.

TABLE OF MAXIMUM DOSES.

Based upon Table A of the Pharmacopœia Germanica, 1882.

In Germany physicians are not permitted to prescribe heroic medicines in larger doses than those given in the table, without adding the sign ! indicating that the larger dose has been intentionally ordered. With very few exceptions, these doses are larger than the maximum doses given by the Belgian Pharmacopœia. The doses of those preparations not contained in or differing materially from those of the German Pharmacopœia, have either been reduced to the United States standard or are quoted from the Belgian or first German Pharmacopœia; they are indicated by x. All doses are intended for adults.

of distilled water at its greatest density (4° C.) was denominated *gram* (Fr. *gramme*), and adopted as the unit of weight. The subdivisions of all measures are named by prefixing to the name of the unit the Latin numerals *deci* (.1), *centi* (.01), and *milli* (.001), and the larger denominations by prefixing the Greek numerals *deka* (10), *hekto* (100), *kilo* (1000), and *myria* (10000).

Rules for Converting Apothecaries' Weights and Measures into their respective Equivalents in Metric Terms for Medical and Pharmacal Purposes.

The following rules are condensed from those prepared by Professor Oscar Oldberg, Phar. D., adopted by John M. Woodworth, M. D., Surgeon-General United States Marine Hospital Service, and approved in 1878 by Hon. John Sherman, Secretary of the Treasury.

1. TO EXPRESS QUANTITIES BY WEIGHT OF THE APOTHECARIES' SYSTEM IN METRIC TERMS, OR TO WRITE MEDICAL PRESCRIPTIONS IN METRIC WEIGHTS.

RULE A. *Reduce each quantity to grains; then divide the number by 10 (or move the decimal point one place to the left), and from the quotient subtract one-third.* The remainder is in each case the number of grams representing (nearly) the same quantity. Or,

RULE B. *Reduce each quantity to drachms, and multiply the number by 4.* The product is in each case the number of grams representing (nearly) the same quantity. Or,

RULE C. *Reduce each quantity to ounces, and multiply the number by 32.* The product is in each case the number of grams representing (nearly) the same quantity.

To illustrate: By Rule B, 4000 Gm. would be (nearly) equivalent to 1000 drachms; but 4000 Gm. is equal to exactly 61,729.40 ÷ troy grains, while 1000 drachms is only 60,000 troy grains. The deviation from exactness, therefore, in the answer arrived at by Rule B (as also in the answers arrived at by Rules A and C), is equivalent to an excess of 1729.40 ÷ troy grains for every 1000 drachms, or about 14 grains for every ounce, or 28.82 ÷ grains for every 1000 grains, or less than 2.9 per cent. To ensure greater accuracy, if in any case deemed necessary, 3 per cent. may be deducted from the answer arrived at by either of the Rules, A, B, or C. The deviation from exactness will then be reduced to $\frac{1}{3}$ of 1 per cent., the remainder being less than the exact equivalent sought by only 2.04 grains for every 1000 grains, or about 1 grain for every ounce.

2. TO EXPRESS QUANTITIES BY MEASURE OF THE APOTHECARIES' SYSTEM IN METRIC TERMS, OR TO WRITE MEDICAL PRESCRIPTIONS IN METRIC CUBIC MEASURES.

RULE D. *Reduce each quantity to minims; then divide the number by 10 (or move the decimal point one place to the left), and from the quotient subtract one-third.* The remainder is in each case the number of cubic centimeters representing (nearly) the same quantity. Or,

RULE E. *Reduce each quantity to fluidrachms, and multiply the number by 4.* The product is in each case the number of cubic centimeters representing (nearly) the same quantity. Or,

RULE F. *Reduce each quantity to fluidounces, and multiply the number by 32.* The product is in each case the number of cubic centimeters representing (nearly) the same quantity.

To illustrate: By Rule E, 4000 Ccm. would be (nearly) equivalent to 1000 fluidrachms; but 4000 Ccm. is equivalent to exactly 64,924.67 ÷ minims, while 1000 fluidrachms is only 60,000 minims. The deviation from exactness, therefore, in the answer arrived at by Rule E (as also in the answers arrived at by Rules D and F) is equivalent to an excess of 4924.67 ÷ minims for every 1000 fluidrachms, or about 41 minims for every fluidounce, or 82.08 ÷ minims for every 1000 minims, or 8.2 per cent. To ensure greater accuracy, if in any case deemed necessary, 8 per cent. may be deducted from the answer arrived at by either of the Rules D, E, or F. The deviation from exactness will then be reduced to less than $\frac{1}{3}$ of 1 per cent., the remainder being less than the exact equivalent sought by only 4.49 ÷ minims for every 1000 minims, or less than 2½ minims for every fluidounce.

Table for Converting Apothecaries' Weights and Measures into Gram Weights.

The gram-values given below are practical approximations to the correct values. The column for *liquids lighter than water* refers to the official spirits and tinctures prepared with stronger alcohol, also to volatile and fixed oils, not exceeding 0.95 in specific gravity. The column for *liquids of specific gravity of water* refers to medicated waters, to tinctures prepared with diluted alcohol, and to fluid extracts prepared with diluted alcohol and alcohol, all having approximately the specific gravity of water. The column for *liquids heavier than water* refers to glycerin, syrups, honeys, and to fluid extracts prepared with glycerin:

Troy weight.	Grams.	Apothecaries' measure.	Grams for liquids.		
			Lighter than water.	Spec. grav. of water.	Heavier than water.
Grain		Minim

Approximate Measures.

In Great Britain prescriptions are compounded by weighing the solids and measuring the liquids, and the same course is very generally followed in the United States; but on the continent of Europe weights alone are employed in the making of preparations as well as in the compounding of prescriptions. Medicines are, however, taken by familiar domestic measures, which are subject to considerable variations, but are usually estimated as having the following capacity:

In the United States.		In France.	
A teaspoonful	1 fluidrachm		5 grams of water.
A deserts spoonful	2 fluidrachms	10	" " "
A tablespoonful	$\frac{1}{2}$ fluidounce	15	" " "
A wineglassful	2 fluidounces		
A glassful	—	150	grams of water.
A teacupful	4 fluidounces		
A tumblerful	8 fluidounces		

The approximate measures by the *handful* (Fr. *poignée*) and pinch (Fr. *pincée*) are almost completely discarded, or employed only for the least active drugs.

The measuring of small quantities of liquids by drops gives very uncertain and variable results, which are influenced by the viscosity of the liquid, the size, shape, and fulness of the vessel, the curvature of the lip, the temperature, the rapidity of dropping, and probably by other circumstances. As a rule, it may be said that aqueous liquids yield larger drops than those containing little or no water; but very different results are obtained with the same liquid dropped from different bottles, or even from the same bottle under different conditions; the differences amount frequently to 50, and occasionally to 200, per cent. For these reasons medicated liquids should not be ordered in drops, but preferably by weight or measure; and whenever it is desirable for the patient to take a medicine by drops, the dose may be approximated by estimating each minim to contain of—

Ether and ethereal solutions	$2\frac{1}{2}$ to 3 drops.
Tinctures, alcoholic solutions, and volatile oils	$1\frac{1}{2}$ to 2 or $2\frac{1}{2}$ drops.
Medicated wines	1 to $1\frac{1}{2}$ drops.
Water and aqueous solutions	$\frac{3}{4}$ to 1 drop.

In order to avoid to some extent the discrepancies resulting from the dropping of liquids under various conditions, dropping-measures (*compte-gouttes*) have been constructed in France, yielding at 15° C. drops of distilled water, 20 of which weigh 1 Gm., at least within a limit of 2 per cent. The French Codex gives a table containing the weight of 1 drop, and the number of drops for 1 Gm. of various liquids, dropped under the conditions stated, which may be summarized as follows:

Number of drops		for 1 Gm. of the following liquids:
20		Hydrocyanic acid, Diluted sulphuric acid, Aqueous solutions of the salts of metals and the alkaloids.
21-26		Mineral acids, Ammonia-water, Glycerin, Fowler's solution, Vinegars.
31		Solution of chloral ($\frac{1}{3}$).
33		Wine (Grenache) and medicated wines.
43		Creasote.
48		Fixed oils.
50-57		Glacial acetic acid, Carbolic acid (alcoholic solution), Alcohol (sp. gr. .864 and over), Chloroform, Volatile oils, Tinctures, Spirit of nitrous ether.
61		Alcohol (sp. gr. .834), Tincture of iodine.
72		Spirit of ether.
90		Ether.

TABLE SHOWING THE RELATION OF THE DEGREES OF BAUME'S HYDROMETERS TO SPECIFIC GRAVITIES.

The hydrometers most frequently used in the United States are those constructed upon the plan of Baumé. For liquids *heavier* than water the point to which the instrument sinks in pure water is 0, and the point to which it sinks in a solution of 15 parts of dry table-salt in 85 parts of water is marked 15, the distance between the two points being divided into 15 equal parts, and the scale continued with divisions of the same size. For liquids *lighter* than water the instrument is floated in a solution of 10 parts of dry table-salt in 90 parts of water, and afterward in pure water, the distance being divided into 10 equal parts, and the scale continued in like manner; the point indicating the density of water is marked 10. The hydrometers were originally constructed at a *medium* temperature. In the United States they are made for the temperature of 60° F. (15.55° C.), and the scales as originally published by Henry Pemberton (1852) are recognized. They agree closely with the determinations made by Schober and Pescher for liquids heavier than water, and differ but little for liquids lighter than water.

Cartier's hydrometer, which is occasionally employed in France, agrees with Baumé's scale for liquids lighter than water, except that 16° of the latter are equal to 15° Cartier.

For Liquids Heavier than Water.

Réaumur's scale is rarely used at the present time; the freezing-point of water is indicated by 0, and the boiling-point by 80°. Therefore 4 degrees of Réaumur are equal to 5 degrees of Centigrade and to 9 degrees of Fahrenheit. The freezing-point of water in Fahrenheit's scales is at 32°.

TABLE OF ELEMENTS.

	Sym- bols.	Atomic value.	Atomic weight.		Sym- bols.	Atomic value.	Atomic weight.
Aluminium . . .	Al	III	27	Molybdenum . .	Mo	II, IV, VI	95.5
Antimony (Stib- ium)	Sb	III, V	120	Nickel	Ni	II, VI	58.1
Arsenic	As	III, V	74.9	Niobium	Nb	III, V	94
Barium	Ba	II, IV	136.8	Nitrogen	N	I, III, V	14
Beryllium (Glu- cinum)	Be	II	9	Osmium	Os	II, IV, VI, VIII	198.5
Bismuth	Bi	III, V	210	Oxygen	O	II	16
Boron	B	III	11	Palladium	Pd	II, IV	105.7
Bromine	Br	I, III, V, VII	79.8	Phosphorus . . .	P	III, V	31
Cadmium	Cd	II	111.8	Platinum	Pt	II, IV	194.4
Cesium	Cs	I	132.6	Potassium (Kali- um)	K	I	39
Calcium	Ca	II	40	Rhodium	Rh	II, III, IV	104.1
Carbon	C	II, IV	12	Rubidium	Rb	I	85.3
Cerium	Ce	III, IV	141	Ruthenium	Ru	II, IV, VI, VIII	104.2
Chlorine	Cl	I, III, V, VII	35.4	Scandium	Sc	III	44
Chromium	Cr	III, VI	52.4	Selenium	Se	II, IV, VI	78.8
Cobalt	Co	II, III, VI	58.9	Silicium	Si	IV	28
Copper (Cuprum)	Cu	I, II	63.2	Silver (Argentum)	Ag	I	107.7
Didymium	D	III	144.6	Sodium (Natrium)	Na	I	23
Erbium	Eb	III	165.9	Strontium	Sr	II, IV	87.4
Fluorine	F	I	19	Sulphur	S	II, IV, VI	32
Gallium	Ga	III	68.8	Tantalum	Ta	V	182
Gold (Aurum) . .	Au	I, III	196.2	Tellurium	Te	II, IV, VI	128
Hydrogen	H	I	1	Thallium	Tl	I, III	203.7
Indium	In	III	113.4	Thorium	Th	IV	233
Iodine	I	I, III, V, VII	126.6	Tin (Stannum) . .	Sn	II, IV	117.7
Iridium	Ir	II, IV, VI	192.7	Titanium	Ti	IV	48
Iron (Ferrum) . .	Fe	II, III, VI	55.9	Tungsten or Wolf- ram	W	II, IV, VI	183.6
Lanthanum	La	III	138.5	Uranium	U	IV, VI	238.5
Lead (Plumbum)	Pb	II, IV	206.5	Vanadium	V	III, V	51.3
Lithium	Li	I	7	Ytterbium	Yb	III	172.7
Magnesium	Mg	II	24	Yttrium	Y	III	89.8
Magnesium	Mn	II, IV, VI	54	Zinc	Zn	II	64.9
Mercury (Hydrar- gyrum)	Hg	II	199.7	Zirconium	Zr	IV	90

In addition to the above, the discovery of the following elements has been announced, but little is known of their properties: Actinium (Ac), Decipium (Dp), Holmium (Ho), Ilmenium (Il), Lævæcium (Lv), Mosandrium (Mo), Neptunium (Np), Philippium (Pp), Samarium (Sa), Terbium (Tb), and Thulium (Tu).

LIST OF REAGENTS

employed in Chemical Testing, according to the United States, British, and German Pharmacopœias.

1. General Reagents and Test Solutions.

For preparing the test solutions and in the application of tests *pure (distilled) water*, free from mineral or other impurities, is used. The proportions adopted by the pharmacopœias are for 1 part of the reagent usually 10 or 20 parts (9 or 19 parts, *P. G.*) of distilled water: when the difference in strength is considerable it is indicated in the following list. All test solutions should be perfectly transparent, and if necessary should be obtained clear by decantation, or, if admissible, by filtration.

Acetic acid: Acetic acid, spec. grav. 1.040 to 1.048.

Boric acid: Boric acid dissolved in 8 parts of alcohol.

Hydrochloric acid: Pure hydrochloric acid, spec. grav. 1.12 to 1.16.

Hydrosulphuric acid: Sulphuretted hydrogen gas generated from sulphide of iron and diluted sulphuric acid: or a fresh saturated solution of the gas in water, 1 part of ferrous sulphide, 1.5 parts of sulphuric acid, and 15 parts of water will generate gas sufficient for about 50 parts of water.

Nitric acid: Pure nitric acid, spec. grav. 1.185 (*P. G.*), 1.420 (*U. S.*).

Nitroso-nitric or Fuming nitric acid: Spec. grav. 1.45 to 1.50.

Oxalic acid: Oxalic acid purified by recrystallization, and leaving no residue when heated to 176.7° C. (350° F.). For solution dissolve it in 10 parts of water.

Picric acid: Crystallized picric acid dissolved in 100 parts of water.

Sulphuric acid: Sulphuric acid, spec. grav. 1.840.

Diluted sulphuric acid: Sulphuric acid, spec. grav. 1.067 (*U. S.*), 1.114 (*P. G.*).

Tannic acid: Tannic acid dissolved in 9 parts of water, with 1 part of alcohol (*U. S.*). (a fresh solution in 19 parts of water, *P. G.*)

Tartaric acid: Tartaric acid dissolved in 5 parts (*U. S.*), 4 parts (*P. G.*) of water; in 8 parts of water with 2 parts of alcohol (*Br.*).

Albumen: The white of one egg dissolved in 100 Ccm. = 3.4 fluidounces (*U. S.*), 4 oz. av. (*Br.*) of water.

Alcohol and Absolute alcohol (see page 140).

Aluminium in the form of wire or ribbon.

Ammonia-water: Pure ammonia-water, spec. grav. 0.960.

Ammonium carbonate: Carbonate of ammonium in small pieces dissolved in 10 (*U. S.*), 20 (*Br.*) parts of water. 1 part ammonium carbonate, 1 part ammonia-water, and 3 parts water (*P. G.*).

Ammonium chloride: Pure chloride of ammonium dissolved in 10 parts of water.

Ammonium oxalate: Crystallized oxalate of ammonium dissolved in 20 parts of water.

Ammonium phosphate: Phosphate of ammonium dissolved in 10 parts of water.

Ammonium sulphide: Saturate 3 ounces of ammonia-water with sulphuretted hydrogen; to this liquid add 2 ounces of ammonia-water.

Barium chloride: Chloride of barium dissolved in 10 parts of water.

Barium nitrate: Nitrate of barium dissolved in 20 parts of water.

Benzol (see page 313).

Bismuth subnitrate (see page 321).

Bromine-water: Bromine dissolved in 40 parts of water.

Calcium hydrate or Lime-water: A saturated solution of calcium hydrate in water.

Calcium chloride: Chloride of calcium dissolved in 10 parts of water.

Calcium chloride, saturated solution: Chloride of calcium 4 parts dissolved in 5 parts of water.

Calcium sulphate: A saturated solution of sulphate of calcium in water.

Carbon bisulphide (see page 386).

Chlorine-water: A saturated solution of chlorine gas in water.

Chloroform (see page 437).

Cochineal solution: Powdered cochineal 3 Gm., alcohol 50 Ccm., water 200 Ccm. It is used as an indicator, the yellowish-red color being changed to violet by alkalies and restored by mineral acids; the color is only slightly modified by carbonic acid.

Copper: Pure thin and bright copper-foil or wire.

Copper acetate: Subacetate of copper 1 part, acetic acid 2 parts, water sufficient for obtaining 10 parts of filtrate.

Copper ammonio-sulphate: Carefully add ammonia-water to test solution of copper sulphate until the precipitate formed is nearly redissolved, and filter.

Copper anhydrous sulphate: Sulphate of copper deprived of its water of crystallization by heat of 205° C. (400° F.).

Copper sulphate: Crystallized sulphate of copper dissolved in 10 parts of water.

Ether (see page 122).

Ferric chloride: Ferric chloride dissolved in 10 parts of water.

Ferrous sulphate: A fresh solution of ferrous sulphate in 10 parts (2 parts, *P. G.*) of water.

Gelatin: Russian isinglass dissolved in 50 parts of warm water.

Gold: Pure metallic gold in the form of leaf.

Gold chloride: Pure chloride of gold (see page 291) dissolved in 20 parts of water.

Guaiacum-paper: Unsized white paper steeped in diluted tincture of guaiacum (1 resin to 100 alcohol) and dried. Used as *Scheerborn's test*: the paper, moistened with diluted solution of copper sulphate, turns blue in presence of free hydrocyanic acid.

Indigo solution or Sulphate of indigo: Heat in a water-bath for one hour indigo 1 part in sulphuric acid 12 parts (20 parts, *Br.*); then add to sulphuric acid 500 parts (1600 parts, *Br.*), and decant from the undissolved powder.

Iodine solution: Iodine 1 part and potassium iodide 3 parts, dissolved in water 50 parts.

Lead acetate: Crystallized acetate of lead dissolved in 10 parts of water; if necessary, add a few drops of acetic acid, so that the solution has a faint acid reaction.

Litmus solution or Tincture: Litmus 1 part, diluted alcohol 10 parts.

Litmus-paper, blue: Unsized white paper steeped in tincture of litmus.

Litmus-paper, red: Unsized white paper steeped in tincture of litmus previously reddened by a very minute quantity of dilute sulphuric acid.

Magnesium hydrate: Precipitate a solution of 3 parts of magnesium sulphate with excess of soda solution: wash the precipitate thoroughly, and then add water to make the weight 10 parts.

Magnesium test solution (ammonio-sulphate): Magnesium sulphate 1 part, ammonium chloride 2 parts, water 8 parts, ammonia-water 4 parts; dissolve and filter, *U. S.* Magnesium sulphate 2 parts, ammonium chloride 1 part, water 18 parts, and ammonia-water 1 part, *Br.*

Magnesium sulphate: Sulphate of magnesium dissolved in 10 parts (2 parts, *P. G.*) of distilled water.

Mercuric chloride: Corrosive sublimate dissolved in 20 parts of distilled water.

Mercury and Potassium iodide: Mix test solutions of mercuric chloride 100 parts, and of potassium iodide 367 parts.

Phenolphthalein: Dissolve phenolphthalein 1 Gm. in 60 per cent. alcohol 100 Gm. The colorless solution is turned red by alkalis, and again colorless by acids, including carbonic acid: used as an indicator.

Platinum black: Platinum in a state of minute division, obtained by adding excess of carbonate of sodium and some sugar to solution of perchloride of platinum, and boiling until a black precipitate is formed, which is washed and dried.

Platinic chloride: Dissolve platinic chloride (see p. 1184) in 20 parts of water.

Potassium acetate: Potassium acetate dissolved in 10 parts (2 parts, *P. G.*) of water.

Potassium bichromate: Potassium bichromate dissolved in 10 parts of water.

Potassium chromate: Potassium chromate dissolved in 10 parts of water.

Potassium ferrieyanide: A fresh solution of potassium ferrieyanide in 10 parts (20 parts, *Br.*) of water.

Potassium ferrocyanide: Potassium ferrocyanide dissolved in 10 parts (20 parts, *Br.*) of water.

Potassium iodate: Digest 5 parts each of iodine and chlorate of potassium, 1 part of nitric acid, and 20 parts of water, until the color of iodine disappears: boil for a minute, evaporate to perfect dryness at 100° C. (212° F.), and dissolve the residue in 430 parts of water.

Potassium iodide: Iodide of potassium dissolved in 20 parts (9 parts, *P. G.*: 10 parts, *Br.*) of water.

Potassium permanganate: Permanganate of potassium dissolved in 1000 parts of water. 62.8 Cem. of this solution, acidulated with 5 Cem. of diluted sulphuric acid, should require 2 Cem. of volumetric solution of oxalic acid for complete decoloration, *U. S.* 0.1 Gm. of pure iron wire dissolved in diluted sulphuric acid should require the addition of 562 Cem. of the test solution before a permanent red color appears, *P. G.*

Potassium sulphate: Sulphate of potassium dissolved in 15 parts of water.

Potassium sulphocyanate: Sulphocyanate of potassium dissolved in 19 parts of water.

Silver ammonio-nitrate: Drop ammonia-water into test solution of silver nitrate until the precipitate formed is nearly redissolved; filter, *U. S.* Crystallized nitrate of silver 1 part, ammonia-water 2 parts, water sufficient to make 40 parts, *Br.*

Silver nitrate: Nitrate of silver dissolved in 20 parts of water.

Silver sulphate: Sulphate of silver dissolved in 250 parts of water.

Soda solution (see page 922).

Sodium: Metallic sodium preserved under petroleum.

Sodium acetate: Acetate of sodium dissolved in 10 parts (*Br.*), 4 parts (*P. G.*) of water.

Sodium bitartrate: A saturated solution of sodium bitartrate in water.

Sodium carbonate: Pure carbonate of sodium dissolved in 10 parts (4 parts, *P. G.*) of water.

Sodium hyposulphite: Hyposulphite of sodium dissolved in 10 parts of water.

Sodium molybdate: Used as *Fröhde's reagent*, which is a solution of 1 part of sodium molybdate in 100 parts of sulphuric acid.

Sodium phosphate: Pure phosphate of sodium dissolved in 10 parts (19 parts, *P. G.*) of distilled water.

Sodium sulphite: Sodium sulphite dissolved in 9 parts of water.

Starch gelatinized: A gelatinous mixture prepared from 1 part of starch and 200 parts of boiling water, *U. S. A.*; a filtered weak solution of indefinite strength, *P. G.*

Stannous chloride: Heat moderately granulated tin 2 parts, hydrochloric acid 7 parts, and water 2 parts, until gas ceases to be evolved; then dilute with sufficient water to obtain 12 parts, and preserve the liquid together with the undissolved tin.

Tin: Metallic tin in the form of a granular powder.

Turmeric solution or Tincture: Bruised turmeric 1 part, alcohol (diluted alcohol, *U. S.*) 6 parts, *Br.*

Turmeric-paper: Unsized white paper steeped in tincture of turmeric.

Zinc: Chemically pure metallic zinc; the absence of arsenic is determined by Marsh's test (see page 27).

Zinc iodide and Starch: Dissolve 4 Gm. of starch by boiling in 20 Gm. of zinc chloride and 100 Gm. of water; add 2 Gm. of zinc iodide, and dilute to 1 liter. It is a test for chlorine, bromine, etc., and is used as an indicator.

2. Volumetric Solutions for Quantitative Tests.

The test liquids for volumetric analysis are made so that one liter contains the hydrogen equivalent ($H = 1$) of the reagent weighed in grams (normal solutions), or one-tenth of this weight (decinormal solutions $\frac{N}{10}$); occasionally centinormal solutions ($\frac{N}{100}$) are used, which are one-hundredth of the normal strength. All the pharmacopœial volumetric solutions are decinormal except those of oxalic acid and soda, which are normal. The solutions of the United States and British Pharmacopœias are identical, and agree also with three solutions of the German Pharmacopœia, while the latter authority has admitted normal solutions of hydrochloric acid and of potassa in place of oxalic acid and soda, potassium bromide ($\frac{N}{20}$) and potassium bromate ($\frac{N}{10}$) for the estimation of phenol, and sodium chloride ($\frac{N}{10}$) for the estimation of silver: in addition to these solutions of cochineal, phenolphthalein, and zinc iodide with starch, described above, are admitted as indicators, and solution of potassium permanganate for the determination of iron.

In the preparation and use of these solutions metric weights and measures are employed: but, for the convenience of those who have not the necessary apparatus and weights, the British Pharmacopœia expresses the quantities of test solutions employed in testing in *grain-measures*, the grain-measure being the volume of a grain of distilled water at 15.55° C. (60° F.). Weight and measure of each system bear to each other precisely the same relation; but since the *gram* is more than fifteen times greater than the *grain*, it will be found convenient, in employing the metric system, to reduce the values of all the numbers to one-tenth of the values of the grains and grain-measures given by the *Br. P.*

Volumetric solution of oxalic acid ($H_2C_2O_4 \cdot 2H_2O = 126$): Pure oxalic acid in crystals, quite dry, but not effloresced, 63 Gm.; distilled water sufficient for obtaining 1000 Cem. (1 liter) of solution. 100 Cem. of this solution contain, in grams, $\frac{1}{10}$ molecule of oxalic acid, and will neutralize $\frac{1}{10}$ of an equivalent in grams of an alkali or alkaline carbonate; as an indicator, phenolphthalein is preferable to litmus (see above). The following articles are tested with this solution: Ammonii carbonas, Aqua ammoniæ fort., *U. S., Br.*; Borax, Liquor calcis, Liq. calcis sacchar., *Br.*; Liq. plumbi subacet., Liq. potassæ, Liq. sodæ, *U. S., Br.*; Liq. potass. efferv., Liq. sodæ efferv., Plumbi acetat., Potass. bitartras, *Br.*; Potassa, Potassii acetat., Potass. permang., *U. S.*; Potass. bicarb., Potass. carb., Potass. citras, Potass. et sod. tartr., Potass. tartras, Soda, Sodii bicarb., Sodii carb., *U. S., Br.*; Sodii carb. exsicc. and Spiritus ammoniæ, *U. S.*

Volumetric solution of hydrochloric acid ($HCl = 36.4$): Hydrochloric acid (sp. gr. 1.124) 146 Gm.; distilled water sufficient for 1 liter. The actual strength of this solution should be determined by titration with volumetric solutions of soda and silver nitrate, or by pure sodium carbonate, and should correspond with the strength of the preceding solution, in the place of which it may be employed except for the lead compounds.

Volumetric solution of iodine ($I = 126.6$): Iodine 12.66 Gm.; iodide of potassium 18.0 Gm.; distilled water sufficient for obtaining 1000 Cem. (1 liter) of solution. 100 Cem. of this solution correspond to 0.17 Gm. of sulphuretted hydrogen, 0.32 Gm. of sulphurous and 0.495 Gm. of arsenious acid. This solution is used as an oxidizer, and is added to the solution to be tested (the latter containing a little gelatinized starch as an indicator) until the blue color ceases to be discharged. The strength is determined by sodium hyposulphite or by pure arsenious acid. The following articles are tested by this solution: Acidum arseniosum, Acid. sulphurosus, Liquor acidi arseniosi, Liq. potass. arsenit., *U. S., Br.*; Potassii sulphis, Sodii bisulphis, Sodii sulphis, *U. S.*

Volumetric solution of potassium bichromate ($K_2Cr_2O_7 = 294.8$): Bichromate of potassium 14.74 Gm.; distilled water sufficient for obtaining 1000 Cem. (1 liter) of solution. 100 Cem. of this solution are capable of converting 1.677 Gm. of iron from the state of ferrous to that of ferric salt. The solution is added to the ferrous solution acidulated with sulphuric acid, and the ferrous salt is known to have been converted into ferric salt when a minute drop of the liquid, placed in contact with a drop of the solution of ferricyanide of potassium on a white plate, ceases to strike with it a blue color. The following articles are tested with this solution: Ferri arsenias, Ferri oxid. magn., Ferri phosphas, *Br.*; Ferri carb. sacch., *U. S., Br.*; Ferri sulphas, Ferri sulphas exsicc., *U. S.* Ferric salts may likewise be tested by this solution after having been previously reduced to ferrous salts by an excess of zinc and diluted sulphuric acid.

Volumetric solution of potassium bromate ($\text{KBrO}_3 = 166.8$): Pure dry potassium bromate 1.668 Gm.; distilled water sufficient for 1 liter.

Volumetric solution of potassium bromide ($\text{KBr} = 118.8$): Pure dry potassium bromide 5.94 Gm.; distilled water sufficient for 1 liter.

On mixing 50 Cem. each of these two solutions, and adding 5 Cem. of sulphuric acid, sufficient bromine is liberated to convert 0.0469 Gm. of carboic acid into tribromophenol. Paper previously steeped in solution of zinc iodide with starch is used as an indicator.

Volumetric solution of potassa ($\text{KHO} = 56$): Solution of potassa free from carbonate, and of such a strength that 15.873 Cem. of it are exactly neutralized by 1 Gm. of oxalic acid, or 100 Cem. by 6.3 Gm. of the acid or by 100 Cem. of the volumetric solution of oxalic acid. The solution may be employed in precisely the same manner and for the same purposes as the volumetric solution of soda.

Volumetric solution of silver nitrate ($\text{AgNO}_3 = 169.7$): Dry crystallized or pure fused nitrate of silver 16.97 Gm.; distilled water sufficient for obtaining 1000 Cem. (1 liter) of solution. 100 Cem. of this solution contain $\frac{1}{100}$ of an equivalent in grams of nitrate of silver (or 1.697 Gm.). This is used by adding it to the solution to be tested, the latter being neutral and containing a little potassium bichromate as an indicator, until the liquid acquires a red tint which does not disappear on stirring. Potassium cyanide may be tested without using the indicator by adding the volumetric solution until the white precipitate just begins to be permanent. The strength of the solution is conveniently determined by $\frac{N}{10}$ solution of sodium chloride. The following articles are tested by this solution: Acidum hydrocyan. dil., Potassii bromidum, *U. S., Br.*; Ammonii bromidum, Potassii cyanidum, Sodii bromidum, *U. S.*; Sodii arsenias, *Br.*

Volumetric solution of soda ($\text{NaHO} = 40$): Solution of soda free from carbonate, and of such a strength that 15.873 Cem. of it are exactly neutralized by 1 Gm. of oxalic acid, or 100 Cem. by 6.3 Gm. of the acid or by 100 Cem. of the volumetric solution of oxalic acid. The solution is used by adding it to the liquid to be tested, the latter containing either solution of litmus or of cochineal or of phenolphthalein as an indicator, until the mixture has a neutral reaction. The following articles are tested with this solution: Acetum, *Br.*; Acid. acet., Acid. acet. dil., Acid. acet. glac., Acid. citric., Acid. hydrochlor., Acid. hydrochlor. dil., *U. S., Br.*; Acid. hydrobrom., Acid. lactic., *U. S.*; Acid. nitro-hydrochlor. dil., *Br.*; Acid. nitric., Acid. nitric. dil., Acid. sulphuric., Acid. sulph. arom., Acid. sulphur. dil., Acid. tartar., *U. S., Br.*; Syrupus acidi hydriodici, *U. S.*

Volumetric solution of sodium chloride ($\text{NaCl} = 58.4$): Dry pure sodium chloride 5.84 Gm.; distilled water sufficient for obtaining 1000 Cem. (1 liter) of solution. This is a decinormal solution, and if mixed with a little potassium bichromate is completely precipitated by an equal volume of the volumetric solution of silver nitrate before the mixture acquires a permanent red tint.

Volumetric solution of sodium hyposulphite ($\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O} = 248$): Dissolve hyposulphite of sodium 32 Gm. in enough distilled water to make the solution measure 1000 Cem. Measure exactly 100 Cem. of the volumetric solution of iodine, and add to it a sufficient quantity of the solution of hyposulphite of sodium, from a burette, nearly to decolorize the iodine solution; then add freshly gelatinized starch, and continue the addition of the hyposulphite until the blue color of the mixture is just destroyed, noting the number (*n*) of Cem. added. Then take of the solution of hyposulphite of sodium ten times (10*n*) this number of Cem., and add thereto enough distilled water to make the solution measure 1000 Cem. (1 liter). 100 Cem. of this solution correspond to 1.266 Gm. of iodine ($\frac{1}{100}$ of an equivalent). The strength is determined by volumetric solution of iodine, of which it should decolorize an equal volume. It is used for the determination of free or liberated iodine by adding it to the liquid until the color of iodine is discharged, a little gelatinized starch being added to the mixture toward the close of the process, and the addition of the volumetric solution being continued until the blue color has just disappeared. The following articles are tested with this solution: Aqua chlori, Calx chlorata, Iodum, Liquor sodæ chloratæ, *U. S., Br.*; Liq. calc. chloratæ, *Br.*; Liq. iodi compositus, Tinctura iodi, *U. S.*

CLASSIFIED LIST OF MEDICAL SURGICAL PUBLICATIONS

ISSUED BY

LEA BROTHERS & CO.,
706 & 708 Sansom Street, Philadelphia.

ANATOMY.

- ALLEN'S** System of Human Anatomy, Including its Medical and Surgical Relations. For the use of practitioners and students of medicine. With an introductory section on Histology, by E. O. SHAKESPEARE, M. D. In six sections, containing 813 double-columned quarto pages, with 380 figures on 109 lithographic plates, and 241 woodcuts in the text. Price per section, in handsome portfolio, \$3.50. Also bound, in cloth, \$23.00; half Russia, raised bands and open back, \$25.00.
- GRAY'S** Anatomy, Descriptive and Surgical. New American from tenth London edition. To which is added the third edition of HOLDEN'S LANDMARKS, MEDICAL AND SURGICAL. In one imperial octavo volume of 1023 pages, with 564 engravings. Cloth, \$6.00; leather, \$7.00; half Russia, raised bands, \$7.50.
- TREVES'** Surgical Applied Anatomy. In one 12mo. volume of 540 pages, with 61 illustrations. Cloth, \$2.00. See *Students' Series of Manuals*, page 1.
- CLARKE & LOCKWOOD'S** Dissectors' Manual. In one 12mo. volume of 396 pages, with 49 illustrations. Cloth, \$1.50. See *Students' Series of Manuals*, page 1.
- CURNOW'S** Medical Applied Anatomy. In one 12mo. volume. (*Preparing*.) See *Students' Series of Manuals*, p. 1.
- WILSON'S** System of Human Anatomy, General and Special. Edited by W. H. GOBRECHT, M. D. In one large and handsome octavo volume of 616 pages, with 397 illustrations. Cloth, \$4.00; leather, \$5.00.
- ELLIS'** Demonstrations in Anatomy; Being a Guide to the Knowledge of the Human Body by Dissection. From the eighth and revised English edition. In one very handsome octavo volume of 716 pages, with 249 illustrations. Cloth, \$4.25; leather, \$5.25.
- ROBERTS'** Compend of Anatomy. In one 16mo. volume of 196 pages. Cloth, 75 cents.
- CLELAND'S** Directory for the Dissection of the Human Body. In one small 12mo. volume of 182 pages. Cloth, \$1.25.
- HOLDEN'S** Landmarks, Medical and Surgical. A new American from the third London edition, with additions by W. W. KEEN, M. D. In one handsome royal 12mo. volume of 148 pages. Cloth, \$1.00.
- SMITH & HORNER'S** Anatomical Atlas, Illustrative of the Structure of the Human Body. In one imperial 8vo. volume of 200 pages, with 634 illustrations. Cloth, \$4.50.
- HORNER'S** Special Anatomy and Histology. Cloth, \$6.00.
- HARTSHORNE'S** Handbook of Anatomy and Physiology. Second edition, revised. In one royal 12mo. volume of 310 pages, with 220 woodcuts. Cloth, \$1.75.
- BELLAMY'S** Student's Guide to Surgical Anatomy. In one royal 12mo. vol. of 300 pages, with 50 cuts. Cloth, \$2.25.

PHYSIOLOGY.

- DALTON'S** Treatise on Human Physiology. Designed for the use of students and practitioners of medicine. Seventh edition, thoroughly revised. In one beautiful octavo volume of 722 pages, with 252 illustrations on wood. Cloth, \$5.00; leather, \$6.00; half Russia, \$6.50.
- FOSTER'S** Text-book of Physiology. New third American from the fourth English edition. In one 12mo. volume of 908 pages, with 271 illustrations. Cloth, \$3.25; leather, \$3.75.
- POWER'S** Human Physiology. In one 12mo. volume of 396 pages, with 47 illustrations. Cloth, \$1.50. See *Students' Series of Manuals*, page 1.
- BELL'S** Comparative Physiology and Anatomy. In one 12mo. volume of 561 pages, with 229 illustrations. Cloth, \$2.00. See *Students' Series of Manuals*, page 1.
- ROBERTSON'S** Physiological Physics. In one 12mo. volume of 537 pages, with 219 illustrations. Cloth, \$2.00. See *Students' Series of Manuals*, page 1.
- DRAPER'S** Medical Physics. In one octavo volume of 734 pages, with 376 illustrations. Cloth, \$4.00.
- CARPENTER'S** Principles of Human Physiology. Edited by HENRY POWER, M. B., F. R. C. S. A new American from the eighth revised and enlarged English edition, with Notes and Additions by FRANCIS G. SMITH, M. D. In one handsome 8vo. volume of 1083 pages, with two plates and 373 engravings. Cloth, \$5.50; leather, \$6.50; half Russia, \$7.00.
- DALTON'S** Circulation of the Blood. In one 12mo. volume of 233 pages. Cloth, \$2.00.
- LEHMANN'S** Manual of Chemical Physiology. Cloth, \$2.25.

CHEMISTRY.

- BLOXAM'S** Chemistry, Inorganic and Organic. New American from the fifth London edition. In one very handsome octavo volume of 727 pages, with 292 illustrations. Cloth, \$3.75; leather, \$4.75.

CHEMISTRY—continued.

- ATTFIELD'S** Chemistry, General, Medical and Pharmaceutical; including the Chemistry of the U. S. Pharmacopoeia, & a Manual of the General Principles of the Science, and their Application to Medicine and Pharmacy. Eighth edition, specially revised by the Author. In one very handsome 12mo. volume of 701 pages, with 87 illustrations. Cloth, \$2.50; leather, \$3.00.
- FOWNES'** Manual of Chemistry; Theoretical and Practical. Revised and corrected by HENRY WATTS, B. A., F. R. S. A new American edition. In one large royal 12mo. volume of 1061 pages, with a colored plate, and 168 illustrations on wood. Cloth, \$2.75; leather, \$3.25.
- HOFFMANN & POWER'S** Chemical Analysis, as Applied to the Examination of Medicinal Chemicals and their Preparations. Third edition, thoroughly rewritten. In one octavo volume of 621 pages, with 179 illustrations. Cloth, \$4.25.
- REMSEN'S** Theoretical Chemistry. With special reference to the Constitution of Chemical Compounds. Second edition, thoroughly revised. In one 12mo. volume of 240 pages. Cloth, \$1.75.
- SIMON'S** Manual of Chemistry. In one 12mo. volume of 410 pages, with 17 illustrations and 7 plates of actual deposits. Cloth, \$3.00; also without plates, \$2.50.
- CHARLES'** Physiological and Pathological Chemistry. In one 8vo. volume of 463 pages, with 38 illustrations and 1 colored plate. Cloth, \$3.50.
- FRANKLAND & JAPP'S** Inorganic Chemistry. In one 8vo. volume of 677 pages, with 51 illustrations and a colored plate. Cloth, \$3.75; leather, \$4.75.
- CLOWES'** Elementary Treatise on Practical Chemistry and Qualitative Inorganic Analysis. Specially adapted for Use in the Laboratories of Schools and Colleges and by Beginners. New American from the fourth and revised English edition. In one very handsome royal 12mo. volume of 387 pages, with 55 illust. Cloth, \$2.50.
- CLASSEN'S** Elementary Quantitative Analysis. Translated with Additions, by EDGAR F. SMITH, A. M., Ph. D. In one handsome royal 12mo. volume of 324 pages, with illustrations. Cloth, \$2.00.
- RALFES** Clinical Chemistry. In one 12mo. volume of 314 pages, with 16 illustrations. Cloth, \$1.50. See *Students' Series of Manuals*, page 1.
- GREENE'S** Manual of Medical Chemistry. In one 12mo. volume of 310 pages, with 74 illustrations. Cloth, \$1.75.
- WÖHLER & FITTIG'S** Outlines of Organic Chemistry. Translated, with Additions, from the eighth German edition, by IRA REMSEN, M. D., Ph. D. In one handsome royal 12mo. volume of 550 pages. Cloth, \$3.00.

DICTIONARIES.

- DUNGLISON'S** Medical Lexicon; A Dictionary of Medical Science; Containing a Concise Explanation of the various Subjects and Terms of Anatomy, Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Medical Jurisprudence, and Dentistry; Notices of Climate and of Mineral Waters; Formulae for Official, Empirical and Dietetic Preparations; with the Accentuation and Etymology of the Terms, and the French and other Synonyms—so as to constitute a French as well as an English Medical Lexicon. By ROBLEY DUNGLISON, M. D. A new edition, thoroughly revised, and very greatly modified and augmented. By RICHARD J. DUNGLISON, M. D. In one very large and handsome royal octavo volume of 1139 pages. Cloth, \$6.50; leather, raised bands, \$7.50; half Russia, raised bands, \$8.00.
- HOBLYN'S** Dictionary of the Terms used in Medicine and the Collateral Sciences. Revised, with numerous Additions, by ISAAC HAYS, M. D. In one large royal 12mo. volume of 520 double-columned pages. Cloth, \$1.50; leather, \$2.00.

MANUALS.

- STUDENTS'** Series of Manuals. A series of 15 manuals by eminent teachers or examiners. Pocket-size octavos of 300-540 pages, richly illustrated. The following may be announced: **TREVES' MANUAL OF SURGERY**, in three volumes; **KLEIN'S HISTOLOGY**, **PEPPER'S SURGICAL PATHOLOGY**, **TREVES' APPLIED ANATOMY**, **POWER'S HUMAN PHYSIOLOGY**, **RALFES' CLINICAL CHEMISTRY**, **CLARKE & LOCKWOOD'S DISSECTORS' MANUAL**, **BRUCE'S MATERIA MEDICA AND THERAPEUTICS**, **ROBERTSON'S PHYSIOLOGICAL PHYSICS**, **GOULD'S SURGICAL DIAGNOSIS**, and **BELL'S COMPARATIVE PHYSIOLOGY AND ANATOMY** (*now ready*). **BELLAMY'S OPERATIVE SURGERY**, **PEPPER'S FORENSIC MEDICINE**, and **CURNOW'S MEDICAL APPLIED ANATOMY** (*shortly*). For separate notices see various subject-heads.

MANUALS—continued.

SERIES of Clinical Manuals. A collection of authoritative monographs in a cheap and portable form. The following volumes are now ready: **MORRIS ON SURGICAL DISEASES OF THE KIDNEY**, **OWEN ON SURGICAL DISEASES OF CHILDREN**, **BUTLIN ON THE TONGUE**, **PICK ON FRACTURES AND DISLOCATIONS**, **SAVAGE ON INSANITY AND ALLIED NEUROSES**, and **TREVES ON INTESTINAL OBSTRUCTION**. The following are in press: **HUTCHINSON ON SYPHILIS**, **BRYANT ON THE BREAST**, **BROADBENT ON THE PULSE**, **LUCAS ON DISEASES OF THE URETHRA**, **MARSH ON DISEASES OF THE JOINTS**, and **BALL ON DISEASES OF THE RECTUM AND ANUS**. For separate notices see various subject-heads.

HARTSHORNE'S Conspectus of the Medical Sciences; containing Handbooks on Anatomy, Physiology, Chemistry, Materia Medica, Practical Medicine, Surgery and Obstetrics. In one large royal 12mo. volume of 1028 closely-printed pages, with 477 illus. Cloth, \$4.25; leather, \$5.00.

NEILL & SMITH'S Analytical Compendium of the Various Branches of Medical Science; for the use and examination of students. In one large royal 12mo. volume of 974 pages, with 374 woodcuts. Cloth, \$4.00; strongly bound in leather, with raised bands, \$4.75.

LUDLOW'S Manual of Examinations upon Anatomy, Physiology, Surgery, Practice of Medicine, Obstetrics, Materia Medica, Chemistry, Pharmacy and Therapeutics. To which is added a Medical Formulary. In one handsome royal 12mo. volume of 816 pages, with 370 illustrations. Cloth, \$3.25; leather, \$3.75.

MATERIA MEDICA AND THERAPEUTICS.

STILLÉ & MAISCH'S Natural Dispensary; containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopœias of the United States, Great Britain and Germany, with numerous references to the French Codex. Third edition, thoroughly revised, with numerous additions. In one magnificent imperial octavo volume of 1767 pages, with 311 accurate illustrations. Cloth, \$7.25; leather, \$8.00; half Russia, open back, \$9.00. Furnished with Patent Ready-Reference Thumb-letter Index for \$1.00 in addition to price in any of above styles of binding.

PARRISH'S Treatise on Pharmacy. Designed as a Text-book for the Student and as a Guide for the Physician and Pharmacist. With many Formulæ and Prescriptions. Fifth edition, thoroughly revised, by THOMAS S. WIGAND, Ph. G. In one handsome octavo volume of 1093 pages, with 256 illustrations. Cloth, \$5.00; leather, \$6.00.

BRUNTON'S Pharmacology, Therapeutics and Materia Medica. In one handsome octavo volume of 1013 pages, with 188 illustrations. Cloth, \$5.50; leather, \$6.50.

STILLÉ'S Therapeutics and Materia Medica; a Systematic Treatise on the Action and Uses of Medicinal Agents, including their Description and History. Fourth edition, revised and enlarged. In two large and handsome octavo volumes of 1936 pages. Cloth, \$10.00; leather, \$12.00; very handsome half Russia, raised bands, \$13.00.

FARQUHARSON'S Guide to Therapeutics and Materia Medica. Third American edition, specially revised by the Author, and edited, with additions, embracing the U. S. Pharmacopœia, by FRANK WOODBURY, M. D. In one royal 12mo. volume of 524 pages. Cloth, \$2.25.

EDES' Text-book of Materia Medica and Therapeutics. In one octavo volume of 500 pages, with illus. (Preparing.)

BRUCE'S Materia Medica and Therapeutics. In one 12mo. volume of 550 pages. Cloth, \$1.50. See *Students' Series of Manuals*, page 1.

MAISCH'S Manual of Organic Materia Medica. Being a Guide to Materia Medica of the Vegetable and Animal Kingdoms. For the use of Students, Druggists, Pharmacists and Physicians. Second edition. In one 12mo. volume of 526 pages, with 242 illustrations. Cloth, \$3.

HERMANN'S Experimental Pharmacology. Translated, with additions, by R. M. SMITH, M. D. In one 12mo. volume of 190 pages, with 32 illustrations. Cloth, \$1.50.

GRIFFITH'S Universal Formulary; containing the Methods of Preparing and Administering Official and other Medicines. The whole adapted to physicians and pharmacists. Third edition, thoroughly revised, with numerous additions, by JOHN M. MAISCOT, Phar. D. In one large octavo volume of 775 pages. Cloth, \$4.50; leather, \$7.50.

PATHOLOGY.

COATS' Pathology. In one handsome octavo volume of 829 pages, with 339 illustrations. Cloth, \$5.50; leather, \$6.50.

GREEN'S Pathology and Morbid Anatomy. Fifth American, from the sixth revised and enlarged English edition. In one handsome octavo volume of 482 pages, with 150 illustrations. Cloth, \$2.50.

SCHÄFER'S Essentials of Histology, Descriptive and Practical. In one octavo volume of 232 pages, with 281 illustrations. Cloth, \$2.25.

CORNIL & RANVIER'S Manual of Pathological Histology. Translated, with Notes and Additions, by E. O. SHAKEPEARE, M. D., and J. HENRY C. SIMES, M. D. In one very handsome octavo volume of 800 pages, with 360 illustrations. Cloth, \$5.50; leather, \$6.50; half Russia, \$7.00.

KLEIN'S Histology. In one 12mo. volume of 360 pages, with 181 illustrations. Cloth, \$1.50. See *Students' Series of Manuals*, page 1.

WOODHEAD'S Practical Pathology. In one 8vo. volume of 497 pages, with 136 colored illustrations in the text. Cloth, \$6.00.

PEPPER'S Surgical Pathology. In one 12mo. volume of 511 pages, with 81 illustrations. Cloth, \$2.00. See *Students' Series of Manuals*, page 1.

PRACTICE.

A SYSTEM of Practical Medicine, by American Authors. Edited by WILLIAM PEPPER, M. D., LL. D. Complete work now ready. In five extra-sized octavo volumes, containing 5572 pages, with 198 illustrations. Per volume, cloth, \$5.00; leather, \$6.00; half Russia, \$7.00. For sale by subscription only.

FLINT'S Treatise on the Principles and Practice of Medicine; designed for the use of Students and Practitioners of Medicine. With Appendix on the Researches of KOCH. Cloth, \$5.50; strongly bound in leather, with raised bands, \$6.50; very handsome half Russia, raised bands, \$7.00.

REYNOLDS' System of Medicine. Edited by H. HARTSHORNE, M.D. In three large octavo volumes of 3056 closely-printed double-columned pages, with 317 illustrations. Per volume in cloth, \$5.00; in leather, \$6.00; half Russia, \$6.50. Sold only by subscription.

BRIISTOWE'S Treatise on the Theory and Practice of Medicine. Second American edition. Edited, with additions, by JAMES H. HUTCHINSON, M. D. In one large and handsome octavo volume of 1085 closely-printed pages. Cloth, \$5.00; leather, \$6.00; half Russia, \$6.50.

HARTSHORNE'S Essentials of the Principles and Practice of Medicine. A Handbook for Students and Practitioners. Fifth edition, revised and improved. In one handsome royal 12mo. volume of 699 pages, with 144 illustrations. Cloth, \$2.75; half bound, \$3.00.

POTTERGILL'S Practitioner's Handbook of Treatment; or, The Principles of Therapeutics. New edition. In one very handsome octavo vol. of about 700 pages. (Shortly.)

THE YEAR-BOOK of Treatment for 1885. A Critical Review for Practitioners of Medicine. A classified summary of medical progress by 23 eminent physicians and surgeons. In one octavo volume of 321 pages. Cloth, \$1.25.

THE YEAR-BOOK of Treatment for 1884. Similar to above. 12mo., 320 pages. Cloth, \$1.25.

WATSON'S Lectures on the Principles and Practice of Physic. A new American from the fifth revised English edition. Edited, with additions, and several hundred illustrations, by HENRY HARTSHORNE, M. D. In two large octavo volumes of 1840 pages, with 190 woodcuts. Cloth, \$9.00; leather, \$11.00.

RICHARDSON'S Preventive Medicine. In one handsome octavo volume of 729 pages. Cloth, \$4.00; leather, \$5.00; half Russia, \$5.50.

BARTHOLOW on Electricity as Applied to the Practice of Medicine and Surgery. New (third) edition. In one 8vo. volume of about 300 pages, with about 125 illustrations. (Preparing.)

BROADBENT on the Pulse. In one 12mo. volume. (Preparing.) See *Series of Clinical Manuals*, page 2.

SCHREIBER on Massage. Translated by MENDELSON. In one 8vo. volume, with illustrations. (Preparing.)

FINLAYSON'S Clinical Manual for the Study of Medical Cases. For the use of Students and Practitioners of Medicine. New edition. In one 12mo. volume of 550 pages, with about 100 illustrations. (Preparing.)

TANNER'S Manual of Clinical Medicine and Physical Diagnosis. Third American from the second London edition. In one 12mo. volume of 392 pages. Cloth, \$1.50.

STURGES' Introduction to Clinical Medicine. In one 12mo. volume of 127 pages. Cloth, \$1.25.

FENWICK'S Student's Guide to Medical Diagnosis. From the third revised and enlarged English edition. In one 12mo. volume of 328 pages, with 87 illustrations. Cloth, \$2.25.

DAVIS' Clinical Lectures on Various Important Diseases. Second edition. In one 12mo. vol. of 287 pages. Cloth, \$1.75.

TODD'S Clinical Lectures on Certain Acute Diseases. In one octavo volume of 320 pages. Cloth, \$2.50.

FLINT'S Essays on Conservative Medicine and Kindred Topics. In one 12mo. volume of 210 pages. Cloth, \$1.38.

BARLOW'S Manual of the Practice of Medicine. Cloth, \$2.50.

STOKES' Lectures on Fever. 8vo., 280 pages. Cloth, \$2.00.

LYONS' Treatise on Fever. In one octavo volume of 354 pages. Cloth, \$2.25.

HUDSON'S Lectures on the Study of Fever. In one octavo volume of 308 pages. Cloth, \$2.50.

LA ROCHE on Yellow Fever, considered in its Historical, Pathological, Etiological and Therapeutic Relations. In two large 8vo. volumes of 1468 pages. Cloth, \$7.00.

ORGANS OF RESPIRATION AND CIRCULATION.

COHEN on Throat and Nasal Passages. New edition. In one octavo volume of 750 pages, with 200 illus. (Preparing.)

SEILER'S Handbook of Diseases of the Throat, Nose and Naso-Pharynx. Second edition. In one 12mo. volume of 294 pages, with 77 illustrations. Cloth, \$1.75.

BROWNE on the Throat and its Diseases. New edition. In one 8vo. volume of about 400 pages. (Preparing.)

FLINT'S Manual of Auscultation and Percussion, of the Physical Diagnosis of Diseases of the Lungs and Heart, and of Thoracic Aneurism. Fourth revised and enlarged edition. In one handsome 12mo. volume of 278 pages, with 14 illustrations. Cloth, \$1.75.

FLINT'S Physical Exploration of the Lungs by Means of Auscultation and Percussion. In one small 12mo. volume of 83 pages. Cloth, \$1.00.

FLINT'S Practical Treatise on the Physical Exploration of the Chest and the Diagnosis of Diseases Affecting the Respiratory Organs. Second and revised edition. In one handsome octavo volume of 591 pages. Cloth, \$4.50.

ORGANS OF RESPIRATION, etc.—continued.

- FLINT** on Phthisis; its Morbid Anatomy, Etiology, Symptomatic Events and Complications, Fatality and Prognosis, Treatment and Physical Diagnosis; in a series of Clinical Studies. In one 8vo. volume of 442 pages. Cloth, \$3.50.
- SMITH** on Consumption; its Early and Remediable Stages. In one octavo volume of 253 pages. Cloth, \$2.25.
- WILLIAMS** on Pulmonary Consumption; its Nature, Varieties and Treatment. With an Analysis of One Thousand Cases to Exemplify its Duration. In one octavo volume of 303 pages. Cloth, \$2.50.
- FULLER** on Diseases of the Lungs and Air Passages; their Pathology, Physical Diagnosis, Symptoms and Treatment. Second edition. In one 8vo. vol. of 475 pages. Cloth, \$3.50.
- LA ROCHE** on Pneumonia. In one octavo volume of 490 pages. Cloth, \$3.00.
- GROSS'** Practical Treatise on Foreign Bodies in the Air-Passages. In one octavo volume of 452 pages, with 59 illustrations. Cloth, \$2.75.
- SLADE** on Diphtheria. In one 12mo. volume. Cloth, \$1.25.
- WALSHE** on the Diseases of the Heart and Great Vessels. In one octavo volume of 416 pages. Cloth, \$3.00.
- FLINT'S** Practical Treatise on the Diagnosis, Pathology and Treatment of Diseases of the Heart. Second and revised edition. In one octavo vol. of 550 pages. Cloth, \$4.00.

ORGANS OF DIGESTION.

- STILLÉ** on Cholera. Its Origin, Causation, Symptoms. Prevention and Treatment. In one 12mo. volume of 164 pages, with a chart. Cloth, \$1.25.
- HABERSHON** on Diseases of the Alimentary Canal. Second American from the third and enlarged English edition. In one octavo volume of 554 pages. Cloth, \$3.50.
- CHAMBERS'** Manual of Diet in Health and Disease. In one handsome octavo volume. Cloth, \$2.75.
- PAVY'S** Treatise on the Function of Digestion; its Disorders and their Treatment. From the second London edition. In one handsome volume, small octavo. Cloth, \$2.00.

VENEREAL AND SKIN DISEASES.

- BUMSTEAD & TAYLOR** on the Pathology and Treatment of Venereal Diseases, including the results of recent investigations upon the subject. Fifth edition. In one octavo volume of 898 pages, with 139 illustrations and 13 chromo-lithographic figures. Cloth, \$4.75; leather, \$5.75; half Russia, \$6.25.
- CORNIL** on Syphilis. Translated by J. HENRY C. SIMES, M. D., and J. WILLIAM WHITE, M. D. In one very handsome octavo volume of 461 pages, with 84 beautiful illustrations. Cloth, \$3.75.
- CULLERIER'S** Atlas of Venereal Diseases. Translated and edited by FREEMAN J. BUMSTEAD, M. D., LL. D. In one large imperial 4to. volume of 328 pages, double columns, with 26 plates, containing about 150 figures, beautifully colored, many of them the size of life. Strongly bound in cloth, \$17.00.
- HUTCHINSON** on Syphilis. In one 12mo. volume. (*Preparing.*) See *Series of Clinical Manuals*, page 2.
- LEE'S** Lectures on Syphilis, and on Some Forms of Local Disease Affecting Principally the Organs of Generation. In one handsome octavo volume of 246 pages. Cloth, \$2.25.
- HILL** on Syphilis and Local Contagious Disorders. In one handsome 8vo. volume. Cloth, \$3.25.
- HUDE** on the Skin. In one very handsome octavo volume of 570 pages, with 66 illustrations. Cloth, \$4.25; leather, \$5.25.
- MORRIS** on Skin Diseases. A Manual for Students and Practitioners. In one 12mo. vol. of 316 pages. Cloth, \$1.75.
- FOX'S** Epitome of Skin Diseases, with Formulae. For Students and Practitioners. Third edition, revised by T. C. Fox, M. R. C. S. In one 12mo. volume of 238 pages. Cloth, \$1.25.
- WILSON'S** Student's Book of Cutaneous Medicine and Diseases of the Skin. In one 12mo. volume of 535 pages. Cloth, \$3.50.
- HILLIER'S** Handbook of Skin Diseases, for Students and Practitioners. Second American edition. In one 12mo. volume of 358 pages, with illustrations. Cloth, \$2.25.

DISEASES OF THE URINARY ORGANS.

- ROBERTS'** Practical Treatise on Urinary and Renal Diseases, including Urinary Deposits. Fourth American from the fourth revised London edition. In one large octavo volume, of 609 pages, with 81 illustrations. Cloth, \$3.50.
- PURDY** on Bright's Disease and Allied Affections of the Kidneys. In one handsome 8vo. volume of 288 pages, with illustrations. Cloth, \$2.00. (*Just ready.*)
- GROSS'** Practical Treatise on the Diseases, Injuries and Malformations of the Urinary Bladder, the Prostate Gland and the Urethra. Third edition, thoroughly revised by SAMUEL W. GROSS, A. M., M. D. In one handsome 8vo. volume of 574 pages, with 170 illustrations. Cloth, \$4.50.
- THOMPSON'S** Lectures on Diseases of the Urinary Organs. Second American edition. In one octavo volume of 203 pages, with 25 woodcuts. Cloth, \$2.25.
- THOMPSON** on the Pathology and Treatment of Stricture of the Urethra and Urinary Fistula. From the third English edition. In one octavo volume of 359 pages, with 2 plates and 47 woodcuts. Cloth, \$3.50.
- LEWIS** on Diseases of the Urethra. In one 12mo. volume. (*Preparing.*) See *Series of Clinical Manuals*, page 2.
- MORRIS** on Surgical Diseases of the Kidney. In one 12mo. volume of 554 pages, with 40 woodcuts and 6 colored plates. Cloth, \$2.25. (*Just ready.*) See *Series of Clinical Manuals*, page 2.

DISEASES OF URINARY ORGANS—continued.

BASHAM on Renal Diseases: a Clinical Guide to their Diagnosis and Treatment. In one royal 12mo. volume of 304 pages, with illustrations. Cloth, \$2.00.

DISEASES OF THE NERVES AND MIND.

- ROSS'** Handbook of the Diseases of the Nervous System. In one octavo volume of 726 pages, with 184 illustrations. Cloth, \$4.50; leather, \$5.50.
- MITCHELL'S** Lectures on Diseases of the Nervous System, Especially in Women. Second edition. In one handsome 12mo. volume of 284 pages, with 5 lithographic charts. Cloth, \$1.75.
- HAMILTON** on Nervous Diseases: their Description and Treatment. Second edition, thoroughly revised and rewritten. In one handsome octavo volume of 598 pages, with 72 illustrations. Cloth, \$4.00.
- CLOUSTON** on Insanity. With U. S. Laws on Custody of Insane, by C. F. FOLSOM, M. D. In one 8vo. volume of 541 pages, with 8 plates. Cloth, \$4.00. Dr. Folsom's Abstract of Laws for sale separately, see below.
- SAVAGE** on Insanity and Allied Neuroses. In one 12mo. volume of 551 pages, with 18 typical illustrations. Cloth, \$2.00. See *Series of Clinical Manuals*, page 2.
- TUKE** on the Influence of the Mind Over the Body in Health and Disease. Second edition. In one octavo volume of 598 pages, with 72 illustrations. Cloth, \$3.00.
- PLAYFAIR** on Nerve Prostration and Hysteria. In one small octavo volume of 97 pages. Cloth, \$1.00.
- FOLSOM'S** Abstract of Statutes of U. S., on Custody of Insane, in one 8vo. volume of 108 pages. Cloth, \$1.50. Also bound with Clouston on *Insanity*, above.
- JONES'** Clinical Observations on Functional Nervous Disorders. In one 8vo. volume of 340 pages. Cloth, \$3.25.

GYNÆCOLOGY.

- THOMAS'** Practical Treatise on the Diseases of Women. Fifth edition rewritten and greatly enlarged. In one large and handsome octavo volume of 810 pages, with 266 illustrations. Cloth, \$5.00; leather, \$6.00; half Russia, raised bands, \$6.50.
- EMMET'S** Principles and Practice of Gynæcology. For Students and Practitioners. New (third) edition, revised and enlarged. In one large octavo volume of 8-0 pages, with 150 illustrations. Cloth, \$5; leather, \$6.00; half Russia, raised bands, \$6.50.
